jects, with scorn unspeakable, the elderly notions of the properties of earth, water, air, and fire, still retains his spasmodic grip of the ether! He (frankly, for once) admits that he cannot work without it. The facts that it is an inheritance of the prehistoric pagan past; that its existence is but based on hypothesis, while entirely beyond the range of logical proof; and that the only statement which can be definitely made in this connection is that the modern conception thereof appears to be explanatory of, and consistent with, most recorded physical facts and observations—not all, unite to attach to our idea of ether a tremulous vitality which appeals all the more effectively to our latent tendencies to chivalrous protection. And the recognition of the origin of all matter from the primitive and universal ether offers another example of the meeting of extremes in the never ending gyration of human opinion. How seldom is the fact recognized, in those "practical" days of fading classical knowledge, when no education is likely to enjoy popular patronage but what promises to yield early results in material cash, that in the grand mythologies of pagan times Jupiter (Zebs, Jis) and Ether (A:07/p) were convertible terms; that the concentrated masses of "fire" were recognized as Apollo (Sun), Diana (Moon), and the "heavenly host" of constellations which represented the semidivinities of heroes and heroines; while fretful Juno ($E\rho\alpha$, which by transposition of a single letter becomes and), with her inexplicable alternations of smiles and tears, and angry frowns and jealous storms, was no other than the atmospheric air; subjacent to, and embraced by, her eternal overlord, Jupiter. Thus:

Tum pater omnipotens fœcundis imbribus Æther Coniugis in gremium lætæ descendit. Vergilius, Georgica, ii, 325.

While a still more significant approximation to the Hebrew cosmogony is represented in the following

A Jove Principium, Musæ: Jovis omnia plena. Vergilius, Bucciica, iii. 60.

The general diffusion of this conception is also testified by the Greek verses of Aratus, the favorite poet of Saul of Tarsus, in the introductory opening of the Phanomena-so dear to "Rome's least mortal mind":

T.z Jos dayerasaba, tar andstat didass some Appretus, asotal de Ilde tadou per apinal. Пада: б алиобтей прини, честь бе наласса. Και κιμένες, παντή δε Διώς γεχώμεθα πάντες To you ras yerns touts which were thus Englished by Mason Good:

"From God we spring-whom men can never trace, Though heard, seen, tasted, felt in every place. The loneliest path, by mortal seldom trod, The crowded city, all is full of God; Oceans, and lakes—for God is all in all— And we are all his offspring.

who also points out that "This is the passage which St. Paul so successfully refers to, and quotes in his animated oration to the Athenians on Mars Hill: 'For in him we live and move and have our being, as certain also of your own poets have said. For see are also his offspring,' Acts, xvii, 28." Thus were the old beliefs gradually prepared for the new revelation. Another of the very remarkable pagan ac-

counts of the powers and functions of omnipotent and omnipresent ether is to be found in the verses of Pacuvius, a poet who was highly appreciated by Cicero and by Horace:

Hoc vide circum, supraque quod complexu continet Terram; id quod nostrei cavum cœlum memorant, Graiei

Quidquid est hoc, omnia animat, format, alit, auget, creat, Sepelit, recipitque in sese omnia; omniumque idem est

Indidemque, eademque, oriuntur de integro; atque eodem

A very remarkable item of pre-Christian testimony, surely, to the presence and properties of the unique elementary source of life, in all its manifestations; above, around, and beneath; animal, vegetable, and mineral! Thus was the universe originally created by ether, out of ether, for ether. And to ether it returns!-according to the very newest of "modern"

Each of the four elements having a particular region alby its motion, either up or down, in a straight line, and where, when it had arrived, it naturally ceased to move. Earth where, when it had arrived, it naturally ceased to move. Earth descended till it arrived at the place of earth; water, till it arrived at that of water; and air, till it arrived at that of air; and there each of them tended to a state of eternal repose and inaction. The spheres consisted of a fifth element which was neither light nor heavy, and whose natural motion made it tend neither to the centre nor from the centre, but revolve around it in a circle. As by this motion they could never change their situation with regard to the centre, they had no place of repose, no place to which they naturally tended more than any other, but revolved round and round forever. This fifth element was subject neither to generation nor corruption nor to altera-tion of any kind; for whatever changes may happen in the heavens, the senses can scarce perceive them, and their appearance is the same in one age as in another. The beauty, too, of the supposed crystalline spheres seemed still more to too, of the supposed crystainle spiners section and more entitle them to this distinction of unchangeable immortality. It was the motion of those spheres which occasioned the mixtures of the elements, and from thence the production of all the forms and species that diversify the world. It was the approach of the sun and of the other world. It was the approach of the sun and of the other planets to the different parts of the earth which, by forcing down the element of fire, occasioned the generation of those forms. It was the recess of those bodies which, by allowing each element to escape to its proper sphere, brought about in an equal time their corruption. It was the period of those great lights of heaven, which measured out to all sublunary things the term of their duration, of their department, and of their decay either in one or a number their growth, and of their decay, either in one or a number of seasons, according as the elements of which they were composed were either imperfectly or accurately blended and mixed with one another. Immortality they could be-stow upon no individual form, because the principles out of which it was formed all tending to disengage themselves and to return to their proper spheres, necessarily at last brought about its dissolution. But, though the individuals were thus perishable, and constantly decaying, every species was immortal, because the subject matter out of which they were made, and the revolution of the heavens, the cause of their successive generations, were always the

The sentences of the foregoing quotation, which explain the origin and significance of the doctrines of astrology and of signature, can hardly, I venture to hope, fail to interest every earnest student of human nature. And so should the following summary of the pagan philosophy of the universe and its ruling Deity

The whole of nature having by their reasonings become equally the object of admiration. was equally apprehended to be animated by a universal deity, to be itself a divinity, and animal; a term which to our ears seems by no means synonymous with the foregoing, whose body was the sensible and solid parts of nature, and whose soul was that

ethereal fire which penetrated and actuated the whole. For of all the four elements out of which all things were composed fire or ether seemed to be that which bore the greatest resemblance to the vital principle which informs both plants and animals, and therefore most likely to be the vital principle which animated the universe. This infinite and unbounded ether, which extends from the centre beyond the remotest circumference of nature, and was endowed with the most consummate reason and in-telligence, or rather was itself the very essence of reason and intelligence, had originally formed the world and had communicated a portion or ray of its own essence to whatever was endowed with life and sensation, which, upon the dissolution of those forms, either immediately or some time after, was again absorbed into that ocean of Deity from whence it had originally been detached. In this system the sun, the moon, the planets, and the fixed stars were each of them also inferior divinities, animated by a detached portion of that ethereal essence which was the detached portion of that ethereal essence which was that soul of the world. In the system of Plato, the intelligence which animated the world was different from that which originally formed it. Neither were those which animated the celestial spheres nor those which informed inferior terrestrial animals regarded as portions of this plastic soul of the world. Upon the dissolution of animals, therefore, their souls were not absorbed in the soul of the world, but had a senarte and eternal existence, which gave birth to had a separate and eternal existence, which gave birth to the notion of transmigration of souls. Neither did it seem unatural that, as the same matter which had composed one animal body might be employed to compose another, the same intelligence which had animated one such being should again animate another. But in the system of the Stoics the intelligence which originally formed, and that which animated the world, were one and the same, all inferior intelligences were detached portions of the great one; and therefore in a longer or in a shorter time were one; and therefore in a longer or in a shorter time were all of them, even the gods themselves who animated the celestial bodies, to be at last resolved into the infinite essence of this almighty Jupiter, who at a destined period should, by a universal conflagration, wrap up all things in that ethereal and fiery nature out of which they had originally been deduced, again to bring forth a new heaven and a new earth, new animals, new men, new deities; all of which would again, at a fated time, be swallowed up in a light conflagration, again to be reproduced, and again to be redestroyed, and so on without end.

The liberal minded and earnestly philosophic student of the opening decade of our twentieth century (who has given some consideration to the antique views which are sketched in the above quotations, and were so formulated by the sages of old in their devoted searchings for wisdom, and unceasing efforts to penetrate, and pluck out the heart of, the mystery of the unknown) cannot fail to be struck by the persistence of the ideas of atom, and molecule, and ether, and intermolecular and interatomic space in the modern science which professes to look upon the Epicurean physics with the same lofty contempt that it does on the Epicurean philosophy. And by the parallelism which may be traced between the cosmic cataclysmal conflagrations of the teaching of the Porch, the universal downward trend of atomic motility to the cosmic abysm of absolute zero of Lord Kelvin and his school-which is also related, though very much less directly, with the everlasting down-raining of atoms taught by Epicurus, and the universal teasing out of cosmic matter into the primordial ether from which it was created, which Le Bon believes to be proved by the conduct of the corpuscular radiations that have been demonstrated within the present decade. Further, also, by the uncanny persistence of that revolutionary movement which animated the star set spheres of the ancient astronomers, and provided the cosmic harmony of Pythagoras, and has at last concentrated itself in the quasi solar system of electronic

(corpuscular) circulation which, we are now assured, constitutes the modern "atom."

That the atom did yeoman service down through the years of the unprecendentedly active and progressive nineteenth century can never for a moment be questioned. Still I will take the liberty of pointing out, in passing, that the argumentative assertion that, as its hypothetical features fitted in-for the most part-so harmoniously with observed facts, and had afforded so fruitful a source of light and guidance in the illumination of the old and the discovery of the "new" knowledge, we were bound to accept the atomic hypothesis as an incontrovertible truth-till some better was laid open to the light of science, affords a specimen of reasoning of a very unhealthy type. It need hardly be pointed out -to the discerning few-that the continued protection of this logically indefensible position would have successfully prevented the penetration of any new scientific light into the previously dark areas of knowledge undiscovered. Yet such has, substantially, been the line of argument adopted by the most prominent of our conservative scientific leaders, even up to present date. But the rampant bull of radiation has burst into our chemicophysical china shop, and ruthlessly "made smithereens" of the cherished atoms for which all its spaces had been so neatly pigeon-holed, and with which they were completely furnished throughout. And here we now are, in the opening decade of the twentieth century, plunged in the mire of the "electron" theory! And almost the only ray of hopeful illumination which has hitherto penetrated this muddy medium has been afforded by the formulation of the view of Le Bon: that all our atoms are being, by degrees, but with a wondrous evolution of explosive energy, resolving themselves-or getting teased outinto the universal ocean of the continuous fluid ether which pervades all cosmic space; whence they all came, and to which they must all return. And now the fact can hardly fail to strike the observer, who knows something of the recorded history of human opinion, that if "scientists" and "teachers" of the recent centuries had been kept informed of the attainments and achievements-theoretical and practical-of their remote predecessors, it would have saved them an incalculable expenditure of time and trouble in the rediscovery of (very rusty) editions of old hypotheses; while it would have preserved an unfortunate (inquiring) public from being periodically deluged by the intellectual emesis of the crudities resulting from the hasty ingestion of characteristically "modern" research and associated ratiocination. Atoms may [come (?) and atoms may] go, but the ether always remains; in all the freshness of its eternal youth, and in all the dignity of its acknowledged omnipotence!

From such preliminary considerations, suggested by the ever inspiring subject of the ubiquitous, and now once more unique, "element," we must hark back when we come to the important discussion of the properties and uses of one of the good old recognized units of elementary matter, in connection with the physiology of the human economy and the therapeusis of the derangements of the same. Man's intimacy with the physical properties of metallic iron, and his consequent utilization of the same for

KNOTT: IRON.

his own practical purposes, are of very ancient date, indeed. They originated in a very primitive stage of the social evolution of the human race; a fact which, in our own generation, is emphatically illustrated by its use among some of the least advanced tribes of Equatorial ("Darkest") Africa. Yet along the pathway of our Western civilization—from the eastern extremity of the Mediterranean, and along the borders of the same—the history of iron does not reach at all so far back into the mists of antiquity as does that of copper, of silver, or of the more rare and coveted gold. I find no evidence that the ferrum of the Romans (καλύψ of the Greeks) was known to the prehistoric inhabitants of those borders. Still its record is quite old enough to elicit respectful consideration. This statement is true not only of its metallurgic history, but of its therapeutic applications. There is no doubt that this metal was extensively employed by the ancient Phœnicians and Egyptians-and their Hebrew slaves; even before the days of Moses. Classical testimony goes to show that it was used by the Greeks at the siege of Troy, not only in the construction of the weapons and machines of war, but in the treatment of wounds as a therapeutic agent. There can be little doubt too, I think, that the original discovery of the loadstone in those Levantine regions, and the unavoidable observation of its weirdly peculiar properties, directed special attention to the qualities of the ores of this metal, and the useful element obtainable therefrom. Regarding the discovery and early (classical) nomenclature of this uncanny mineral, we are told by the learned (and pugnacious) Gideon Harvey, "Dr. of Phys. and Phil." (1663), that:

The loadstone is otherwise called a magnete from the first inventor thereof, Magnes, who garding his heard upon the Mount Ida, felt his slip-shoes, being fastned with Iron pegs, to stick fast to the ground, and his driving staffe, which was pegged at the bottom with an Iron peg, to stick fast likewise, whereat he was much astonisht, but searching narrowly into the cause he found they were a sort of stones that held him.

The Greeks named the stone Sideritis, which Pliny, lib. xxxvi, cap. 16, derives from σίδηρος, iron; and not without a just ground, it having a vertue of attracting Iron to it. Others knew it by the name of Lapis Heraclius, not derived from Hercules, or Heraclius, the supposed Inventor, but from Heraclia, a City of Lydia, where the best were found in great number. The Germans call it ein Seilstein, or a sailstone, because the Mariners sail by it.

And the same up to date natural philosopher (of the days of the Protectorate and of Puritanical ascendancy, of the Restoration and the foundation of the Royal Society) proceeds to further enlightenment of his readers in this connection, thus:

This stone changes its name by the places where it is usually found.

1. The Magnesium Loadstone is engendred about the City Magnesia.

An Alexandrian Loadstone is taken up about Alexandria.

3. It is found in Echio, in Bœotia.
4. The worst of them, being spungy and loose, are found near the Cape Verlychi in Natolia.
5. The best are those of Æthiopia, being the blewer,

heavier, and drawing Iron stronger.

And, as might be expected in the discussion of a natural product furnished with properties so strangely and unaccountably unique as those of the native loadstone, some illustrative magnetic mythol-

ogy is thrown in for the reader's further enlightenment:

923

Tasnierius supposing them to grow in the bottom of the Æthiopian Sea, relates an odd story, that some Ships crossing the Æthiopian Sea, and bearing near to the Promontories should have been drawn to the bottom of the Sea by some Loadstones taking hold of their Iron Pins.

(Can we be surprised that the wise Egyptians of old, whose territory was limited in one direction by that body of water, always held the practice of nav-

igation in abhorrence?)

Dr. Harvey, who had been "Physitian to his Majesties Army in Flanders," would appear to have imported the spirit of the physics of the "Father of Modern Philosophy" from the vicinity of the birthplace of the latter. For his theory of the load-stone has, I should say, been imbibed from that of Descartes-with a classical flavoring derived from the metrical Epicurianism of Lucretius:

The loadstone is (as it were) imperfect iron, but not so near resembling it as iron resembles steel. It is between a stone and a metal, and therefore in a manner is not per-fectly concocted. Its material principle is a loose earth rarefied by dense fire and incrassated air, being unequally mixt and tempered. Its forma ultima is sometimes a compleat metal like to iron, other times like to a hard reddish blew stone. Both these have been found by many, not knowing what to make of them, which in all probability were concocted loadstones. That they were loadstones is were concorred foatstones. That they were to adsorbines we evidenced by the remaining vertues, although but very weak of attracting iron. Its body being throughout porous (that is loose and not very solid,) its intrinsick parts must of necessity partake of a certain figure as all porous bodies do, although in some more, in others less. Iron it self (as also a lyzzard stone) consists of intrinsick parts cuspidally or pyramidally formed, that is with streaks transcurring as it were into pyramidal points. . . . The cause you as it were into pyramidal points. as it were into pyramidal points. The clause you know is from the manner of exhalation and proruption of the ayry and fiery parts that have left it, and minutely do still leave it. Between these triangular pointings we do imagine insensible cavities or pores, through which those emanations do continually pass, and by whose figure they are directed to their passages outward; those I say are continuous and very potent.

Manifold and multiplex have been the modifications of the atomic hypothesis of the structure of matter since the above paragraph was printed-in the infantile days of the Royal Society. And we could afford to look back (and down) on Gideon Harvey's hypothesis with a more lofty (or pityingly philanthropic) contempt than we do, had it not been for the fact that rust, the most familiar of all oxides (or comopunds) of iron, has not even yet had the mystery of its genesis and growth satisfactorily unveiled by the most curious of our twentieth century scientists! However various readers may contemplate such facts of the history of the progress of human opinion, I think it my duty to note that our philosophic Harvey, which his conception appears distinctly suggestive of Cartesian inspiration, is most vigorous in his efforts to tear to pieces the magnetic theories of the great philosopher of the Netherlands. On the other hand, his silence regarding the "Enquiries" of his own countryman, Sir Thomas Browne, who had exposed a good few of the "vulgar errours" in connection with this same subject, would seem to be almost correspondingly significant. Indeed, he reduces the theoretical views and opinions of the father of modern philosophy on this head to the position of the absurdest of most absurd absurdities! And, as both the Cartesian and Harveian hypotheses are based upon emanations (or radiations), the expressed criticisms of the emphatic Gideon Harvey should perhaps be considered wor thy of some passing attention in a generation which is just now "muddling through" the cosmopolitan throes of a radioactive revolution. And thus we find them written—introduced with a lecturer's bow, of which the modest dignity will be appreciated by the philosophic reader:

let me take the leasure to balance what Cartesius sets down upon this matter. After the enumeration of the properties of the magnete, he observes that there are striated particles, that are sent down from the south part of heaven, and bowed quite into another kind of shape, different from those that rain down from the north; whence it is that the one cannot enter into those channels and passages which the other can. He further observes, that the south particles do pass directly from their seat through the midst of the earth, and when passed return back again with the air that is cast about the earth, because the passages through which they pass are such that they cannot return back again through the same. The like is to be understood of those particles that pass through the earth from the north. In the mean time as many new parts as there do alwaies come on from the south and north part of the heavens, so many there do return or fall back through the east and west parts of the heavens, or else are dis-persed in their journey, and lose their figures, not in passing the middle region of the earth, because there their passages are made fit for them, through which they flow very swiftly without any hindrance, but in returning through the air, water, and other bodies of the outward earth, wherein they find no such passages, they are moved with much more difficulty, and do constantly meet with particles of the second and third element, by which they laboring to expel them are sometimes diminisht.

Now in case these striated particles hit against the loadstone lying in its natural position, then they find a clear passage to go through, because (he saith) a loadstone is pervious in the same manner as the earth is, and therefore

calleth the earth also a magnete.

The poles of the loadstone he states to be the middle points of its passage on both ends. That which is the middle point between the passages that are disposed to receive the particles descending from the north part of the heavens, is the north pole, and its opposite is the south

ole.

But when the striated particles that come from the poles of the earth hit against the passages of the magnete lying athwart, then they do by that force, which they have of persevering in their motion according to right lines, impell it untill they have reduced it to its natural position, and so they effect that its south pole (provided it be not detained by any external force), turns towards the north pole of the earth; Because those particles that tend from the north pole of the earth through the air to the south, came first from the south part of the heavens through the midst of the earth, and the others that return to the north, came from the north.

Having given the reader this preliminary sketch of the position occupied by the scientist whom he proposes to discredit, he proceeds to indicate more definitely the vulnerable points of the same, and to utilize them in the process of disruption of his defences. And with this object in view the advance is made along the following lines of attack:

Here you have the chief of the forementioned Author's fansic upon the demonstration of the properties of the Loadstone. In thirst place, how can any one probably conceive that there are striated parts sent down from heaven; for consider the immense distance, (which he agrees to) the interposition of thick clouds filled up with dense exhalations, and the continuous depth of the air. Is not the air potent enough to dissolve all bodies contained within its bowels, doth it not dissolve the thick frozen clouds into snow, hail, and thick rain? Doth it not dissolve the coagulated exhalations of the earth, that are so tenacious? Much more those striated parts, which he himself confesse are dissipated at their return through the force of the am-

bient air, and that in so short a time and passage. Why should these striated particles descend more from the polar regions of the heavens, than from the east and west parts? Are not the poles of the heavens immovable, of the least efficacy? Are not those parts of the firmament alwaies discerned to be clearest, and most freed from obscure bodies? Is not the north and south air so much condensed and congealed, that it is impossible for it to give passage to such subtil bodies as the pores of the magnet do require? I say impossible to subtil bodies, because they need force to press through; and so much the more, because they are discontinuated. But had our author asserted them to rain down from the east and west parts, where the air is thinnest and less nebulous, and where the celestial bodies exercise their greatest influences, it would have deserved a freer reception; but then his chimera would have been rendred monstrous, and unfit to explain the reasons of the magnetical vertues.

The south streaks (saith he) are intorted in a form different from those of the north; whence had he that news? What? Because one pole of the magnete inclineth to the north, and the other to the south, therefore these streaks must needs be sent down from the north and south. this a mathematical demonstration to conclude the cause (and a false one too) by the effect? A notion far inferior to those of the wanderers, and that which adds to this absurdity is to imagine that these streaks should retain their shape notwithstanding their continual and long grinding against the air in their descent, and not change their shape a hundred times over. Doth not a cloud, which must be supposed to be of a firmer consistency than those particles, make choice of a new shape every moment? how much the more these small tender bodies? And that which is most absurd is, to propose that such a vast number or troops of these particles should arrive hither into our north hemisphere from the south so obliquely without changing their shape; further he supposeth them to come heaving down directly through the earth, and through the magnete, which is impossible, unless it be in a right sphære; whereas we here are situated in a very oblique sphere, and consequently the magnete is also obliquely seated here, wherefore it is requisite that those streakes should alwaies beat against the magnete in these regions obliquely, and change their shape very oft. But how monstrous it is to maintain these particles to flie through the diameter of the earth and water, being bodies most

So sinks the spirit of scientific thought, which had animated the "father of modern philosophy," and to which people less well informed than Dr. Gideon Harvey had given so prominent a niche in the temple of intellectual fame (!). And to prevent the remotest probability of resuscitation, he does not neglect to administer a coup de grace (or two):

dense, close & thick in many places shutting out fire and

air, being substances by a million of degrees exceeding Des-Cartes in subtility; or how is it possible they should pass the most icy and deep thick body of water? well, and

yet through all this difficulty they should retain their shape;

this is an absurdum absurdissimorum absurdissimum.

The earth is pervious in such a manner as to fit the shape of the collestial streakes: and were it so, it certainly moving about the sun according to his assent must change its passages and so thwart the entrance of the coelestial subtilities.

As for the passages of the magnete, we grant them to be numerously seminated through its body, but their shape is quite different. My time doth even weary me in making disquisition upon so dishering and monstrous a chimera; I should easier give credit to Rabelais his Pantagruel, or the Fables of Æsope, than to so obtuse a phantasm.

The structural theory formulated by our critical Harvey as a basis on which to ground his own explanation of the physical peculiarities of the load-stone appears to me to occupy approximately the position of a halfway house between the supersubtle atomic lucubrations of Lucretius and the amazing complexities of the *electron*—and other contemporary—theories which have been arrayed for the

purpose of lighting up the hazy domain of the infancy of radioactivity. It is as follows:

perament through streams or small mixtures of the elements gradually deserting the decocting bodies, and taking their egress or fuming through their pores. These pores tend most from the transcurrent axis towards the north. That its pores tend most towards the north is evident by That its poles tend most towards the north is vertein by its intrinsick parts within (as you may see when it is cut through) running variously intorted towards the north in streaks; these streaks are distinguisht from one another through interjacent porosities, otherwise they would be continuously one. That the loadstone emits fumes, is testified from its looseness and inequality of mixture: For all parts, (as I have shewed before,) that are unequally mixt, suffer a discontinuation of their mixture, because that one element being predominant, and having its force united through the said unequal mixture, must needs make way for its effumation, and afterwards break through by egressing fumes; but such is the loadstone. Ergo. 2. That these fumes or effluvia do effumate through their northerly pores, the experiment it self doth confirm to us; For we see that they attract steel most at the north side; besides, they usually rub the cross wires of sea compasses at the north side, as being most effumous there. Thus much for the $\delta r t$, and part of the $\delta t \delta r t$. Now for the manner of its attraction, and here it is disputed whether the loadstone attracts iron, or iron the loadstone. Hereunto I answer, that neither the loadstone doth properly attract iron, or iron it: However since iron is moved toward the loadstone (but accidentally) by means of his effluvia or steames, therefore the loadstone is said to draw iron to it. Iron doth (improperly) move it self to the loadstone, being incited to the same motion through the steames of the loadstone entering through its pores into its substance. The streams of the loadstone are through their particular form and external shape or figure fitted to enter into the pores of iron, which are in like manner fitted to receive the streams of the loadstone; they being admitted do reservate the substance of iron, or through their specifick penetrability do free the volatil parts of that iron from the fixt ones, whence they do immediately through their fiery principle dilate and diffuse themselves towards that part of the circumference, where they feel the continual effumations of the loadstone yet more to unite them, which reeking out, and being further diducted by a continuation of succeding parts, do draw the course parts along with it, as being still continually united to them. Or plainer, the said fumes of the loadstone having entered the pores of iron do immediately loosen the spirits of the iron, which being dilated and united to the fumes of the loadstone must needs cover a greater place, the want of which causeth them both to spout out at those holes, which are most patent; which must necessarily be those, through which the magnetical fumes entered. This sudden spouting out must cause an attraction of the iron, because the extrinsick air doth suddenly enter its pores on the opposite side, for to recover a place within the Iron which it had lost without by being driven back out of its place by the prorupting fumes: This sudden irruption of the air on the opposite side drives the iron forwards to that place whence it was first repelled.

This you will the better understand if you compare it with our discourse set down in the chapter of Local Mo-

tion, and of a Vacuum.

These steams of the iron do effumate through all the pores, where the vertue of the loadstone hath touched it, especially at the centre of opposition to the stone, whence they breaking out in great quantity, do draw the body of iron directly towards the loadstone: But if the objected Iron be defended by being besmeared with Oil or any other greasie substance, or by being dipt into water, it puts by and obtuses the fumes of loadstone. That the loadstone doth effuse fumes from it, is further made known to us,

1. Through its inequality of mixture and looseness of

substance, as I hinted before.

2. Either it must act, that is, attract at a distance, or else operate through streams; it cannot act at a distance, that being only proper to supernatural agents, and denied to all natural ones; ergo the last.

3. If you burn it it will cast a visible blew sulphureous

smoky flame

4. It is not the iron doth primarily effuse steams towards

the loadstone, because it is more compact, and less exhalable. Hence Scaliger might now have resolved his doubt, whether the loadstone drew iron, or iron it. Why these fumes do exhale most towards the north, we have told you al-

Do not let it seem strange to you, that the emanations of this stone should reserate the mixture and temperament of iron; it being common to many other bodies, although authors are not pleased to take notice of it. The fumes of mercury do open the body of gold. The heat of the sun opens the body of water, and attracts Vapours thence. Amber through its emissives attracts dust, paper, &c. But of these elsewhere.

Why the stone moves steel variously according to its diverse position happens through the variety and obliquity directing its steames, and variously withal entering the

pores of the objected steel.

It must be admitted, I think, by all unprejudiced and inquiring readers, that this theory, while obvi-ously straining to be "all musical in its immensities," and inspiring in the supernatural insight of its intellectual (as well as physical) revelations, has succeeded in becoming almost as confusing in its complexities as any twentieth century theory of the structure of matter which has been produced since the invention of the Crookes's radiometer, and the development of the first Röntgen ray photograph! -and that is putting it as strongly, perhaps, as the scientific facts and the English language can conveniently permit. Those who have studied the cosmic theory elucidated in the (almost divinely inspired) metres of Lucretius will probably survey with the slenderest estimation the progress which had been made in the evolution of the atomic hypothesis from the days of the pre-Christian poetic apostle of Epicurus, down to those of the Flemish "Father of modern philosophy," and the English exponents of science in the years of the infancy and childhood of the Royal Society. And some of us cannot help wondering to ourselves, sometimes, what would Moschus and Lucretius, and Descartes and Sir Thomas Browne, M. D., and Gideon Harvey, M. D., and-let us, with special significance. add—Sir Isaac Newton, think of the present ultrachaotic condition of our shipwrecked and shattered atom; to say nothing of the hypothetical stability of our theory of the propagation of light (undulatory or corpuscular?). Whatever may be the visionary reply to this dreamy interrogative, it is of some interest to note that Lucretius, as he was evidently unable to avoid taking notice of the mysterious mineral, does not fail to apply the atomic system of his great master to the explanation of its unique phenomena, and in a way which offers something more than a merely plausible suggestion that Descartes drank therefrom the nectar of his own "magnetic" inspiration. Our metrical pagan philosopher, after the prefatory introduction of this subject to the notice of his reader:

> Quod super est, agere incipiam quo fœdere fiat Naturæ, lapis hicc' ut ferrum ducere possit, Quem Magneta vocant, patrio de nomine Graiei, Magnetum quia sit patriis in finibus ortis,

proceeds to give a luminous panoramic sketch of the facts and arguments derivable from the other aspects and domains of nature which appear specially to support his system, or to be most rationally explicable thereby; and then goes on to concentrate all the rays of the mental vision thus called up to the mind's eye of the inquirer:

Quapropter, bene ubi hæc, confirmata atque locata, Omma constiterint, nobis præposta, parata; Quod superest, facile hine ratio reddetur, et omnis Caussa patefiet, quæ ferri perliceat vim.

Principio, fluere e lapide hoc permulta necesse est Semina, sive æstum, qui discutit aera plagis, Inter qui lapidem ferrumque locatus. Hoc ubi inaniter spatium, multusque vacefit In medio locus; ex templo primordia ferri In vanum prolabsa cadunt conjuncta, fit utque Annulus ipse sequatur, eatque ita corpore toto. Nec res ulla magis, primoribus ex elementis Indupedita suis, arte connexa cohæret, Quam validi ferri naturæ frigidus horror Quo minus est mirum, quod dicitur; ex elementis Corpora si nequeunt, de ferro plura coorta, In vacuum ferri, quin annulus ipse sequatur Quod facit; et sequitur, donec pervenit ad ipsum Jam lapidem, cæcisque in eo conpagibus hæsit. Hoc fit idem cunctas in parteis; unde vacefit Quomque locus, sive ex transvorso, sive superne, Corpora continuo in vacuum vicina feruntur Quippe agitantur enim plagis aliunde, nec ipsa Sponte sua sursum possunt consurgere in auras.

Huc adcedit item, qua re queat id magis esse: Quod simul a fronte est annelli rarior aer Factus, manitusque locus magis, ac vacuatus; Continuo fit, utei, qui post est quomque locatus Aer, a tergo quasi provehat, atque propellat. Semper emin circum positus res verberat Sed tali fit utei propellat tempore ferrum, Parte quod ex una spatium vacat, et capit in se. Hic tibi, quem memoro, per crebra foramina ferri Parvas ad parteis subtiliter insinuatus Trudit, et inpellit: quasi naves velaque ventis.

Hæc quoque res adjumento, motuque, juvatur. Denique, res omnes debent in corpore habere Aera, quandoquidem raro sun corpore, et aer Omnibus est rebus circumdatus adpositusque. Hicc' igitur, penitus qui in ferro est abditus, aer Solicito motu semper jactatur, eoque Verberat annellum, dubio procul; et ciet intus Scilicet: atque eodem fertur, quo præcipitavit

Jam semel, et vacuam partem in conamina sumpsit. Fit quoque, ut a lapide hoc ferri natura recedat Interdum: fugere, atque sequi, consueta vicissim. Exsultare etiam Samothracia ferrea vidi;

Ac ramenta simul ferri furere intus ahenis In scaphiis, lapis hic Magnes quom subditus esset: Usque adeo fugere a saxo gestire videtur Aer interposito; discordia tanta creatur Propterea, quia nimirum prius æstus ubi æris Præcipit, ferrique vias possedit apertas; Posterior lapidis venit æstus, et omnia plena Invenit in ferro; neque habet qua tranet, ut ante: Cogitur obfensare igitur, pulsareque fluctu Ferrea texta suo: quo pacto respuit ab se, A que per æs agitat, sine eo quod sæpe resorbet.

Illud in iis rebus mirari mitte, quod æstus Non valet e lapide hoc alias inpellere item res. Pondere enim fretæ partim stant; quod genus, aurum; Ac partim, raro quia sunt cum corpore, ut æstus Pervolet intactus, nequeunt inpellier usquam: Lignea materies in quo genere esse videtur. Inter utrasque igitur ferri natura locata, Æris ubi adcepit quædam corpuscula, tum fit, Inpellant ut eam Magnesia flumina saxi.

The skilled student will not fail to perceive at a glance that the intellectual fissure which distinguishes the magnetic theory of our pre-Christian philosophical poet from that of the "father of modern philosophy" is one which can be crossed without the exercise of long jumping powers. The cousin germanship of their physical conceptions, surely, is very readily recognizable. The view of Descartes was criticised (unfavorably, of course) by Gideon Harvey, M. D., his English junior contemporary; and the emphatic and self confident version of the latter will not fail to throw collateral illumination on the text of the metric apostle of Epicurianism, as well as on the validity of the rival claim of the "modern" Netherlands philosopher to the afflatus of atomic inspiration. Harvey wrote as follows:

The poles of the loadstone are directly coincident with those of the air. You see its poles are primarily neither perpendicular to those of the heavens or of the earth: Ergo its poles do appropriate a particular situation. But before I prove their seat it will not be improper to prefer the probation of the ori of their poles. The emanations of the loadstone move circularly; ergo they must have real poles or immovable points, for a body is uncapable of a circular motion in all its parts. A real axis is no less necessary; It being impossible to conceive two extream immoveable points in a globous body without being fastned or continuated to other fixt points, (which must likewise remain void of the same circular motion) and so on from one extream point to the opposite extream point. That the steames of the said stone affect a circular motion is evident, in that the continuous effuvia of all bodies convert themselves into a like motion. Doth not the thick smoak of coales, of gunpowder, of boyling water, in fine of all things in the world turn themselves round in the open air? What is it you can cast up into the air but it will incline to a circular motion? Do not those little atoms that are seen by us in the rayes of the shining sun (the same which some author is pleased to term light it self, probably be-cause the sun through its reflection and refraction upon them engrosses its light, so as to render them, to be light glistering bodies to the eye,) make choice of a turning and winding motion? Which if so, what reason is there to move us to detract the said motion from the continuous steames of the Heraclian stone? Authors I remember, as Gilbert, Cabeus, Kircher, and others are accustomed to pronounce the loadstone to contain a collection of all the proporties of the earth in her, and reciprocally the earth to partake of the qualifications of the loadstone, but without reason: Nevertheless I may justly set down that the loadstone is enricht with all the dignities and vertues of fire and air; for as fire and air attract, move circularly, are diffused to the periphery, even so doth this stone. Here we may equally imagine poles, axis, polar, circles, æquator, meridian, horizon, a common and proper motion, &c.

These well defined conceptions of the author receive further demonstrative illustration with the aid of an elaborate diagram, in which those gyratory motions are clearly depicted. And the twentieth century student is forcibly reminded of the persistence of the idea of circular atomic movement in this connection, from the era of the original Academy down to that of the invention of the circum-molecular electromagnetic currents of Ampère! Also of the coexistent tendency to the culture of the megacosm and microcosm: in the philosophical conceptions of the zόσμος and μιχροχόσμος of the "divine" founder of the academy; of the earth and loadstone as the cosmic great and little magnets, respectively; and of our twentieth century universe, and its individual electronified atom, as the respective "imperial" and "miniature" "editions" of our intermediate solar system!

Harvey's version of the curious prophetic anticipation of the nineteenth century telegraph is thus mentioned towards the close of his chapter "Of the loadstone":

There yet remains a word or two touching the fabulous property of this stone, which you have described, by Famianus de Strada, Libavius, and others, viz., that two load stones although at a great distance, do so sympathize with one another, that they move at one another's passive impulsion, and that towards the same place; as, for two friends residing in different countries, and intending to sig nife their meaning or desires to each other, they are only to make use of two steel needles, of an equal size, & to rub them both on the same side of the magnete, and afterwards to place them in a compass box, and so turning either of the needles to any point of the compass, the other is thought to obey to the same motion, whereby they come to know one another's meaning, as having mutually at their last meeting agreed to impose a certain signification upon each point of the said compass. Hence they deduce a magnetical (or like to it) sympathy in curing of wounds, a sympathy in the affinity of bloud, a sympathy between the guts and their excrements, between superlunary and sublunary bodies, between men and men, men and beasts, men and plants, beasts and beasts, sheasts and plants, some natural bodies and other: So that whereas formerly philosophers used to excuse their ignortice by occult qualities, now having worn them out they accur to magnetical sympathies. There is not a surgeon or apothecary so ignorant, but he will as cunningly find out a cause whereby to explain the most abstruse effect of Nature, and instantly tell you such or such an effect happens through a magnetical sympathy, as the most learned Mr. Doctor. But is this the great advancement of learning and philosophy which our age doth so much boast of? Is it not rather a grand piece of impudence to propose such absurdities, and much more to give credit to them?

His famous contemporary, Sir Thomas Browne, was less opinionative—and conspicuously more charitable—in his comment on the current magnetical hypothesis, and the apostles and disciples of such doctrines:

Now whether these effluviums do flye by streated atomes and winding particles as Renatus des Cartes conceaveth, or glide by streames attracted from either pole and hemispheare of the earth unto the æquator, as Sir Kenelme Digby excellently declareth, it takes not away this vertue of the earth, but more distinctly sets downe the gests and progresse thereof, and are conceits of eminent use to salve magneticall phenomena's. And as in astronomy those hypotheses though never so strange are best esteemed which best do salve apparencies, so surely in philosophy those principles (though seeming monstrous) may with advantage be embraced which best confirme experiment, and affect the confirmation of the confirmati ford the readiest reason of observation. And truly the doctrine of effluxions, their penetrating natures, their invisible paths, and insuspected effects, are very considerable; for besides this magneticall one of the earth, severall effusions there may be from divers other bodies, which invisibly act their parts at any time, and perhaps through any medium, a part of philosophy but yet in discovery, and will I feare prove the last leafe to be turned over in the booke

(This last sentence is, I venture to suggest, one specially worthy of the attention of the present philosophical student and of the future candid historian of the genesis and evolution of our twentieth century doctrine of radioactivity!)

The very critical, and somewhat lengthy, discussion of the "magneticall vigour of the earth," by the earnest and philosophic author of the *Religio Medici*, shows very clearly that the ventilation of "Biot's hypothesis" was not quite new to the scientific atmosphere—although the fact may have long been forgotten, or deliberately ignored, by the superficially scientific majority.

For these effluxions penetrate all bodyes, and like the species of visible objects are ever ready in the medium, and lay hold on all bodyes proportionate or capable of their action; those bodyes likewise being of a congenerous nature doe readily receive the impressors of their motor; and if not fettered by their gravity, conforme themselves to situations, wherein they best unite unto their Animator.

And his examination of the phenomena of "inclination or declination of the loadstone," and of the "variation" of the same, although occasionally deficient in precision of nomenclature, and not illuminated with a sufficient number of experimental facts—as known to the student of the present day, shows clearly that rapid and well defined progress had been made in the domain of magnetic science during the forty-six years which had intervened between (its original foundation by) the publication

of Gilbert's *De Magnete* (in 1600) and that of Browne's *Pseudodoxia* (in 1646). The writer introduces an interesting speculation regarding the latter property of the magnet, and the (possible) influence which (a due foreknowledge of) the same might have exercised in maritime exploration, which, I venture to hope, will be found of special interest to American readers even in the twentieth century.

The variation of the compasse is an arch of the horizon intercepted between the true and magneticall meridian, Now the cause of this variation may be the inequalitie of the earth, variously disposed, and differently intermixed with the sea: withall the different disposure of its magneticall vigor For whereas on this side of the meridian, or the Isles of Azores, where the first meridian is placed, the needle varieth eastward, it may bee occasioned by that vast tract of earth, that is, Europe, Asia, and Africa, seated toward the east, and disposing the needle that way: For arriving at some part of the Azores, or Islands of Saint Michaels, which have a middle situation betweene those continents, and that vast and almost answerable tract of America, it seemeth equally distracted by both, and diverting unto neither, doth parallel and place it self upon the true meridian. But sayling farther it veers its lilly to the west, and regardeth that quarter wherein it is nearer or greater; and in the same latitude as it approacheth the shoare augmenteth its varialatitude as it approached the shoate augmentation and therefore as some observe, if Columbus or whosoever first discovered America, had apprehended the cause of this variation, having passed more than halfe the way, he might have been confirmed in the discovery, and assuredly foretold there lay a vast and mighty continent toward the west. The reason I confesse, and inference is good, but the instance perhaps not so. For Columbus knew not the variation of the compass, whereof Sebastian Cabot first took notice, who after made discovery in the northern part of that continent. And it happened indeed that part of America was first discovered, which was on this side farthest distant, that is Jamaica, Cuba, and the Isles in the Bay of Mexico. And from this variation do some new discoveries deduce a probability in the attempts of the northerne passage toward the Indies. . . But if in certain creekes and valleys the needle prove irregular, and vary beyond expectance, it may be imputed unto some vigorous part of the earth, or magneticall eminence not far distant. And this was the invention of Dr. Gilbert not many yeeres past, a physition in London. And theregood, but the instance perhaps not so. For Columbus knew not many yeeres past, a physition in London. fore although some assume the invention of its direction, and others have had the glory of the Carde, yet in the experiments, grounds and causes thereof, England produced the father philosopher, and discovered more in it, then Columbus or Americus did ever by it.

And we feel sure that scientists of every country, who regard the acquisition of true knowledge as a nobler pursuit than that of the culture of national prejudice, will allow that England has good reason to be proud of her medical sons: William Gilbert, the "father of the science of magnetism," and Thomas Browne, the faithful exponent of philosophic Christianity, and enthusiastic iconoclast of the time honored "errours" of the "learned vulgar." And I will just take the opportunity of adding, in way of running comment, that a deplorably instructive lesson in the modes of estimate of human reputation may be derived from the comparison of the twentieth century fame of those two members of our profession, on the standard critical scale of the "learned vulgar" of the present day, with that of the legal "Father of experimental philosophy," Francis Bacon, who discoursed so prophetically, and advised so judiciously, regarding the culture of those sciences of which he knew nothing—and very often less; while setting himself with all his power to overturn the authority and methods of Aristotle, the vast bulk of whose attainments he had never

mastered; and actually sneering—in the clumsiest fashion, too—at the enthusiastic application of the now so called "Baconian method" to the investigation of the properties of the loadstone, by which his contemporary (medical) neighbor had, in the metaphoric sarcasm of the great Lord Chancellor, "almost himself become a magnet." Such is the value of the British national standard measure, as an indicator of the value of relative reputations, in the estimation of true scientific attainment and of genuine philosophic merit!

(To be continued.)

REPORT OF SIXTEEN CASES OF ACHYLIA GASTRICA.*

By A. E. Woehnert, M. D., Buffalo.

Achylia gastrica is a condition of the stomach in which no gastric juice is secreted. Some of these cases are undoubtedly due to disturbed innervation and should be classed as neuroses. Others are plainly due to organic changes which have taken place in the gastric mucosa, and, through long continued chronic inflammation, a destruction of the glands of the stomach has been brought about. Achylia gastrica is an ætiological factor in pernicious anæmia and forms a part of the symptom complex of that disease. Achylia is also found in gastric cancer, and cancer should be excluded before a diagnosis of achylia is made. Many of these cases give a history of long continued digestive trouble; in some no such history is obtained, and the condition of the stomach is discovered accidentally in a routine examination. It is surprising how well these patients get along without their gastric diges-They do not lose very markedly in weight, the intestine is able for a time at least to carry on satisfactorily the entire work of digestion. These patients do well as long as the gastric motility is properly maintained. When the food taken is per-sistently improper in character, the intestine may gradually give out, and we have a characteristic diarrhœal condition induced.

The diagnosis of achylia depends upon the results of a chemical and microscopical examination of the stomach contents. The methods of examination are as follows: The patient is instructed to take an Ewald breakfast consisting of a roll and a glass of water, or bread and butter and a glass of water. The stomach is examined one hour after this test meal. One is struck by the difficulty of obtaining a reflow in conditions of achylia. In a majority of cases it is almost impossible to obtain undiluted stomach contents. The contents when obtained are noticeably pale and watery; the food is practically in the state in which it was taken, and appears simply water logged. Where a test dinner of Hamburger steak and bread and water is given, the meat shows no change by digestion.

The chemical analysis of the filtrate yields an acidity of from two to six degrees, and test for free hydrochloric acid shows that it is absent. Tests for combined chlorides are also negative. The biuret

reaction is absent, and a test for starch digestion shows also failure here. The tests for rennin and pepsin and their zymogens are also negative. Occasionally we may find a trace of lactic acid present, but it is not constant and usually not large in amount. The microscopical examination of the contents shows undigested meat fibres, the strize can be plainly seen showing no attempt at meat digestion. A few yeast cells may be seen, no Oppler-Boas bacilli or sarcinæ are found; some mucus may be present.

Examination of the stools may be important, particularly in those cases where there is a lienteric diarrhea. They are yeasty and offensive and contain mucus. Microscopically, we find meat fibre in large quantity totally unchanged; starch granules may also be found. In those cases where the bowel irritation has been of long standing, gross, un-

changed particles of food may be found.

During the last few years out of several hundred cases of stomach trouble, some sixteen cases of achylia gastrica have fallen under my observation. Of these patients eleven were female and five of them were male sex. They ranged in age from twenty-eight years of age to sixty years. The average age was forty-two years. Some of these patients did not complain of gastric disturbance. Case V sought relief for persistent headache; one patient had attacks of shortness of breath, and several of them complained of general weakness and palpitation. A very characteristic symptom was a diarrhœa, which is seen in many of these cases. Von Tabara (Münchener medizinische Wochenschrift, 1904) observed typical diarrhœa in twenty per cent. of his cases. It occurred periodically in three and persistently in one of these cases, or twenty-five per cent. Pain simulating the pain of hyperchlorhydria was a feature in two of my cases. Einhorn (New York Medical Journal) reports six cases with pain. Nausea and vomiting were distressing features in two of these cases, and were only relieved by porsistent lavage. Most of my patients complained of discomfort and fermentation after food was taken. The gas was so large in amount in several cases as to produce shortness of breath and palpitation. As stated before, loss of weight was not a striking feature; on the contrary, the majority of these patients appeared well nourished. Constipation was the feature in several, and a mild colitis was occasionally found in conjunction with gastric trouble. Having in mind the fact that achylia is found in many cases of pernicious anæmia, the blood was carefully examined as to its quality and quantity. Anæmia was found in five of these cases and was of a secondary type. The hæmoglobin ranged from thirty-five per cent in the severest to eighty per cent. in the mildest case. Aside from the moderate reduction in hæmoglobin, there was nothing noteworthy in the stained specimens. The red cells ranged from 3,200,000 in the severest to a trifle below the normal in the milder cases. The white cells were unchanged. The urinary examination revealed nothing noteworthy except an excessive amount of indican.

Achylia gastrica is a disease which is slow and insidigus in its progress, and the ætiology would be of necessity somewhat obscured. Bad teeth, with resulting insufficient mastication, throwing the mechanical part of digestion on the stomach, is a factor

^{&#}x27;Prop before the Lighth District Bronch of the Medical Society 61 to the of Society Vick, Battivia, September 23, 1968

of some importance. I have many times removed large pieces of meat which had been bolted without apparently any mastication. As these cases were cases of subacidity and were tending toward achylia, it seems to me reasonable to consider this as an æti-

ological factor.

That many of these cases belong to the neuroses has been stated, and causes leading to nerve exhaustion must be considered as ætiological. Eyestrain, worry, overwork, lack of rest and sleep are among such causes. One of my patients had an exophthalmic goitre which affected her nervous system. Those cases that are due to atrophic changes have as ætiological factors all causes of a chronic sclerosing gastritis, such as alcohol, syphilis, tea drinking, etc. Leo (Münchener medizinische Wochenschrift, 1906) declares that there is no evidence that achylia occurs without some anatomical changes in the stomach. There is no way by which the functional case can be distinguished from the organic except by clinical observation of the course of the case. Occasionally fragments of mucosa are found in the wash water, and histological examination of these fragments often give some hint as to the condition of the gastric mucosa. Where the fragment shows interstitial and atrophic changes it would be fair to assume that we had to deal with a case of achylia due to organic changes.

The physical examination of these cases was of value only in a general way. The anaemic patients, five in number, had generally undeveloped musculature. The stomach was low in some, and in several well marked clapotage was elicited. Those presenting diarrhœa had more or less gurgling and unrest in stomach and bowels. The majority of my patients presented nothing unusual in a physical way which would point to a gastric anacidity.

Achylia gastrica, occurring as it does in middle life, must be distinguished from cancer. The chemistry of the two conditions is very similar. In cancer we have, in conjunction with the physical signs of a tumor, a tendency to food stagnation. Lactic acid is present persistently in considerable amount. We have also the cachexia and rapid loss of weight in cancer. In achylia, as we have seen, the majority of patients are well nourished. Lactic acid is present inconstantly and only in small amount, and there is no tendency to food stagnation.

When the condition is functional, the prognosis is good for a return to normal. It may be and usually comprises a considerable period, a year or more, before acid and ferments make their appearance. In three of my cases the stomach secreted gastric juice inside of a year's time. The other thirteen cases apparently belong to a group caused by organic changes, and although some of them have been under more or less irregular treatment for years, I have failed to find any suggestion of the return of acid or ferments. As long as the patients select their diet with care, they go about their business apparently as well as anybody, and are able to lead a fairly active life. A certain proportion have exacerbations from time to time and need to be kept under more or less observation.

The treatment resolves itself into measures that will improve the local condition of the stomach and if possible restore the secretion of gastric juice.

Diet is of the greatest importance. These patients lack the dissolving action of the gastric juice, so that their intestinal digestion is carried on at a great disadvantage. As long as the food is conducted into the intestine in small amounts and at proper intervals the intestine does very well. When we have a relaxed pylorus as well as achylia, the food passes directly through the patulous pyloric opening into the intestine, the intestine is unable to handle this properly and an irritable condition is brought about which results in a lienteric diarrhœa. These patients should be instructed to prepare the food for the intestine. The meats should be soft and tender and finely divided. When there is a tendency to loose bowels, all foods containing an excess of cellulose should be omitted from the diet, and only the cooked and mashed vegetables and fruits should be allowed. The absence of free hydrochloric acid is a handicap in more than one way. Its antiseptic action in the intestine and stimulating action on the Our patient pancreatic secretion are missing. should be instructed to masticate his food thoroughly, and if the teeth are bad he should be sent to a dentist for treatment.

Hydrochloric acid and pepsin are indicated in these cases. Of course we cannot hope to supply enough of either to carry on digestion as it is normally carried on. I have been in the habit of using the concentrated acid in four or five drop doses, which would equal a drachm of the dilute acid. The effect is good, and many of these patients have taken the acid for years and feel that they cannot get along without it. Even the small quantity that we give seems to improve the digestion, particularly of the intestine. The lienteric diarrhœa will often cease when the diet is regulated and acid and pepsin are given. I have found that several of my patients have required lavage at regular intervals. They are able to get along for a few days or weeks, and then are troubled with gas or pain unless they have local treatment. I have been in the habit of using a mild silver solution after the stomach has been cleansed, and washing the silver out after it has been in contact with the mucous membrane for a moment or so. The intragastric faradism also seems of benefit particularly in those cases where relaxation is pronounced and the stomach empties rather quickly. Nux vomica and condurango act well as local and intestinal tonics. The nux vomica and electricity, diet and acid, have apparently restored the secretion in the functional cases. Occasionally it is necessary to employ peptonized milk for a day or so to rest the intestine. Where there is colitis bowel washes are useful. The extract of pancreas often does better than pepsin in these cases. Massage, general faradism, hydrotherapy to improve the general tone are also indicated in many cases. When there is anæmia iron is indicated. The cases with organic changes have exacerbations which have to be met with symptomatically. Curiously enough, those patients who have pain are relieved by alka-

In conclusion, a brief résumé of the history and chemical findings in these cases is given.

CASE I.—Mrs. E. J. M., aged fifty, married, born in the United States. Patient gave a history of having distress an hour after eating. There was more or less gas, she was

short of breath upon exertion. Her appetite was good, weight 135 pounds. She was anamic. Hæmoglobin 75 per cent. She was constipated, and gave a vague history of stomach trouble for a number of years. Lavage three hours after test dinner: Hamburger steak and bread and water; reflow very poor, bread and meat unchanged, total acidity two degrees, no free acid, no combined acid, no biuret; pepsin and rennin negative; contents very pale. Patient was put upon appropriate diet and improved.

Case II.—Mrs. G., thirty-five years of age, married, United States. This patient had had looseness of the bowels for the past two years, particularly at night. She was troubled with shortness of breath after meals; appetite variable; tongue clean; patient was anamic, very delicate looking, and was decidedly neurasthenic. Bowels were loose even if they moved only once a day; patient weighed ninety-five pounds; hæmoglobin 75 per cent.; right kidney was displaced to the second degree. Stomach had been examined many times during the past year, the acidity fluctuating between two and ten degrees. Examination for free hydrochloric acid was negative, combined negative, no biuret; rennin and pepsin negative. The meat and bread showed no digestive changes. Contents were pale, usually considerable in amount. Patient under treatment had made only moderate improvement, having periods of diarrhea.

Case III.—Mrs. C., at. forty-three, widow, Swede. Patient had always been well up to nine years ago, since then had more or less distress after eating. There was considerable gas, particularly at night. She had had a number of painful attacks like gastralgia, coming on as often as once a week; the patient was well nourished; right kidney was displaced in the first degree, appetite good, tongue clean, bowels inclined to be constipated. Examination of the stomach after test dinner: Contents pale, meat and bread unchanged, total acidity four degrees, no free hydrochloric acid, no combined acid, no ferments. The patient was treated from time to time for a year, when free hydrochloric acid began to appear; she has been practically well since

Case IV.—Mrs. K. R., sixty-two, widow, born in German. Gave a history of bowel trouble for ten years. When she was at her best bowels moved four times a day; had frequent attacks where bowels moved almost continuously. Had attacks of collicky pain over the sigmoid. Her appetite was poor; her food did not distress her. Patient was very nervous. She was anæmic; hæmoglobin seventy-seven per cent. Examination of the stomach after all kinds of test meals showed a total acidity of from four to six degrees; free or combined acids were never found; rennin and pepsin absent; contents pale, food was practically unchanged. This patient improved greatly under appropriate diet and artificial gastric juice.

propriate diet and artificial gastric juice.

Case V.—Mrs. J. D., forty, married, United States. Had
never been strong; had had sick headaches for twenty
years, two or three times a week. Her weight was 125
pounds; she was anæmic, hæmoglobin forty-nine per cent.
The anæmia was not of a pernicious type. Bowels were
occasionally loose. Examination of stomach contents after
Ewald breakfast: The contents were pale and showed no
digestion. Free and combined acids were absent, rennin
and pepsin negative. Under appropriate diet and medication and frequent lavage, the patient improved; her bowels

became less active and her headaches disappeared.

Case VI.—Mrs. J. J., aged thirty-four, married, Canadian. Had never been strong. Family physician treated her for nervour prostration. Had had more or less trouble with gas in stomach and palpitation after eating for the last three years. The patient was anæmic and thin. Three hours after a test dinner, no free hydrochloric acid, no combined acid; rennin and pepsin negative. Food showed no digestion. Two weeks later lavage was again instituted. The stomach was practically empty and two sprouting lemon seeds were obtained through the tube. The total acidity was at this time six degrees; there was no free or combined acids, no rennin or pepsin. This patient's stomach contained so little acid material and the conditions were so favorable that lemon seeds were able to provide

Case VII.—O. C., female, aged thirty-five, single. Had been troubled with nausea lasting for a considerable period. These attacks of nausea came and went; her appetite was capricious; patient was nervous and gave a history of stomach trouble dating over a number of years. Her

mother died of pernicious anaemia. Three hours after a test dinner: The total acidity was six degrees, no free or combined acid, no rennet or pepsin, no biuret. Food practically unchanged, bowels costive. Patient after some treatment gained rapidly and was in fairly good health for a number of warrs, when the requisit developed and she died

number of years, when tuberculosis developed, and she died.

Case VIII.—J. W., male, thirty-nine years of age, married. The patient gave a history of constipation all his life;
his appetite was poor as a rule; he complained more of
brain fag and the general weakness of neurasthenia than
of gastric trouble; he weighed 126 pounds; the patient was
spare. One hour after a test breakfast: The food showed
practically no change; the total acidity was four degrees,
free and combined acids absent, biuret absent, rennin and
pepsin absent. Subsequent examinations gave the same
chemistry. Under diet and intragastric faradism the patient improved generally, but not locally.

tient improved generally, but not locally.

CASE IX.—Mrs. B. F., aged sixty, married. There was a history of specific trouble in this case; she was a well nourished and very neurotic woman, and gave a history of nausea and vomiting after meals for a period of several months. Contents after a test meal showed poorly changed and poorly masticated food; total acidity from two to four degrees; no free or combined acids, no pepsin or rennin; biuret absent; some mucus present. After rather regular gastric lavage, the nausea was relieved, the chemistry remained unchanged.

Case X.—Mrs. F., aged twenty-eight, married. Patient was well up to a year ago, when she began to have severe gastric pain. Pain was increased by eating; her appetite was fair, bowels costive; pulse rate was high, from 108 to 120. She had a moderate sized goitre; her weight was 111 pounds. Examination two hours after bread and water: Contents pale, food was practically unchanged; total acidity four degrees; no free or combined acids present; no rennin; no biuret. Subsequently, under treatment, gastric interesting of the case.

remmi; no blurer. Subsequently, under treatment, gastric juice returned in this case.

CASE XI.—Mrs. A. N., aged forty-two, Swede. Patient had not been well for twenty-three years; had had more or less trouble with stomach during this time. For the past few years had had looseness of bowels. Her bowels moved from eight to twelve times a day; some tenderness over the stomach and bowels. Lately she had had some colicky pain. Weight was 140 pounds.; she was a nervous woman. A number of examinations after the usual test breakfast showed invariably no digestion; contents always pale; total acidity varied from four to ten degrees; no free or combined acids were found at any time. This patient improved somewhat after a course of lavage and regulation of diet

Case XII.—H. W., male, forty-eight years of age, carpenter. Patient had a lemon yellow color; he gave a history of being in good health up to two years ago. Had been troubled with shortness of breath and weakness; this had been increasing lately. Blood analysis: Hæmoglobin thirty-five per cent, leucocytes 8,000, red blood corpuscles 3,200,000; cells were anæmic; no macrocytosis, an occasional normoblast was found. Examination of stomach one and half hours after a test breakfast: Contents pale, food unchanged; total acidity six degrees; no free or combined acids, no pepsin or rennin. Patient was put on large doses of iron, his diet was regulated, and he was given hydruchloric acid and pepsin. He improved steadily, and six weeks later the hæmoglobin was seventy-five per cent. He went to his home in Denver and had not been hard irom

CASE XIII.—B. M. X., male, thirty-five, married. Patient had had more or less gastric trouble for some years; he had been very irregular as to meals; he had more or less pain in the region of the pylorus; lately he had had periods of severe pain in the precordial region; he complained of gas in the stomach; a week before this patient was seen he had severe pain and vomiting; he had had attacks of pain and vomiting every few weeks; there was considerable tenderness over the epigastrium. He was constipated; his tongue was coated. Fifty minutes after a test breakfast, the food was unchanged, contents pale, considerable mucus; no free or combined acid, no rennin or pepsin, no biuret. Total acidity ten degrees. A subsequent examination, a few weeks later, gave practically the same results. The patient was put on lavage, diet, and hydrochloric acid and pepsin. He was seen some months later, and after a test meal at bed time, the contents

showed poor digestion, total acidity of fourteen degrees, free hydrochloric acid six degrees; traces of rennin and

pepsin.

CASE XIV.—Mrs. M., aged forty-five. Gave a history of more or less gas and distress in the stomach; occasional attacks of severe headache; one hour after a test meal food was unchanged, contents pale, total acidity four degrees; no free or combined acid, no ferments; bowels reg-The patient was instructed as to diet; was given large doses of acid and improved as to distress in the

stomach. The chemistry of the stomach upon subsequent examinations was found to be the same.

Case XV.—E. M., male, thirty-two years of age. Patient complained of looseness of bowels which move directly after eating; he had been troubled in this way for Examination of stomach one hour after a test breakfast: Food unchanged, contents pale, no free or combined acids, no ferments. Examination of the stools showed a large amount of undigested meat. Patient was treated with lavage and faradism. He was instructed as to diet and given hydrochloric acid. A few weeks after treatment was instituted an intractable joint affection developed, practically a rheumatoid arthritis. This joint con-

dition up to the present resisted all treatment.

CASE XVI.—Miss K., aged fifty, school teacher. Patient gave the history of gastric trouble lasting over a period of several years. She was nervous, had more or less vertigo, and she had lost weight and strength, and was very much depressed. Examination of stomach one hour after test breakfast and many subsequent examinations showed an acidity varying from four to six degrees. There was no free or combined acid found at any time, and no ferments. Food was always practically unchanged. Under lavage, diet, with large doses of free hydrochloric acid, the patient improved generally, but not locally.

56 ALLEN STREET.

ADIPOSIS DOLOROSA.

Diagnosis. The Result Of Surgical Treatment. BY THEOPHIL KLINGMANN, M. D., Ann Arbor, Mich.

While this condition is not a distinct entity, Dercum applied the term "adiposis dolorosa" to a symptom complex which is pathologically closely allied to acromegalia, myxœdema, and exophthalmic goitre. Authors of the more recent textbooks on diseases of the nervous system place adiposis dolorosa with the conditions referred to under one common head

"trophoneurosis."

As the name implies the condition is characterized by accumulation of fat usually localized in which there is pain and tenderness, and in connection with this asthenia is a prominent symptom. The pain may be more or less continuous with paroxysms of sharp darting pain which is usually described as neuralgic in character. The asthenia is variable, it may be very marked or entirely absent. In a number of cases reported no mention is made of this condition. Occasionally the psychic phenomena are pronounced, patients being apathetic and depressed and often very irritable.

Without going into details' as to the variability of the symptoms and many other conditions which may arise during the course of the disorder it is worthy of emphasis that the pain is the most prominent and distressing symptom. It is this that brings the patients to seek medical aid. Pressure over the fatty deposits always causes pain. Often there is more or less constant pain described by the patient

as rheumatism or neuralgic pain.

The case which I am about to relate is interesting not only because it is a rare condition but also from the standpoint of diagnosis, which was doubtful as the condition was associated with hysteria.

CASE.—The patient a woman, forty-nine years of age, of healthy appearance, very stout, with a somewhat awk-ward gait, applied for treatment at the University Hospital on account of pain and localized swellings in various parts of the body. She was entered in the service of Dr. C. D. Camp, who referred her to me for special study and to whom I am indebted for the opportunity of seeing her

History.-The father and mother died at an advanced The mother was of a nervous temperament, one sister died at the change of life and two sisters during infancy. There was no history of tumors or constitutional disease, no nervous disorder or insanity. The patient was well during early childhood; when she was eleven years old she had a severe fall, and at sixteen she was accidentally thrown from a wagon, in consequence of which she became very nervous, was easily excited, and often very irritable. On several occasions she was overcome by marked weakness in the legs, causing her to fall on her knees, but was never unconscious during these attacks.

Later she noticed a similar condition in her arms and hands. She became awkward in holding objects, and frequently dropped things out of her hands. Menstruation began when she was eleven years old. She was always regular, the flow normal, and she had no pain. She was treated for uterine disease which she states was an ulcerated uterine cervix. At the present time she is passing through the menopause. She was married at twenty-five, two years later she became suddenly totally paralyzed following a seizure during which she stated she was un-conscious. Her body was rigid, her head retracted, the back arched, and the legs flexed upon the thighs. She also lost her voice and was unable to speak for three years The paralysis following this attack gradually disappeared, but lasted over a period of three years. During the time she was confined to bed her weight increased to the extent of 100 pounds, her total weight reaching 303 pounds. breasts became very large and very painful. The p The panniculus flabby and pendulous, overhanging the pubes and inguinal region in an apronlike fashion.

Present illness .- The patient's chief complaint was pain in the left axilla and the posterior part of the left thigh, where there were distinct swellings. She had paroxysmal sharp stinging pain in these localities and more or less wandering pain in various parts of the body which she described as rheumatism. Her arms and legs felt heavy and occasionally numb, and she had a feeling of general exhaustion. For several years she has had frequent attacks of vomiting and diarrhea lasting two or three days at a time. She stated that the vomiting was not preceded by nausea and that the stools were green with considerable mucus. Frequent micturition disturbed her sleep at night. She had become forgetful and at times stupid. Two years ago she had both breasts removed on account of the pain and the discomfort caused by their enormous size. She was much better and quite free from pain for some time. About this time she first noticed the swelling in the axilla and posterior part of the thigh. She stated that these swellings were painful on pressure, gradually

grew larger, and the pain became more severe.

Examination.—The patient was very corpulent, weighing about 280 pounds, panniculus abundant and flabby, hanging in folds over the abdomen. The hands and wrists were small, also the forearms were comparatively free from excessive fat. The feet and ankles were also small, the right leg slightly larger than the left, the thighs were very large. There was a tumor like mass in the posterior portion of the right thigh just above the popliteal space, another somewhat larger mass in the outer part of the same thigh, and the third in the right axilla. These masses were somewhat more firm than the surrounding tissue, more or less circumscribed and very painful on palpation. skin over the thorax and arms was warm and elastic and not adherent to the subjacent structures. There were two large, well healed scars the result of breast amputations. There were no enlarged glands. About the scleral vessels there were light yellow deposits of fat. The movements of the eyes were normal, the pupils equal, and they reacted

For a complete review of the subject and a detailed description of the same I refer the reader to a paper by Dr. Jules B. Franken-heumer, Journal of the American Medical Association, No. 13, March 28, 1968.

to light and in accommodation. There was no facial palsy, and the tongue protruded in the median line. I showed good resonance over the entire front. râles were occasionally heard over the right apex, bronchovesicular breathing in the right apex, vesicular in the left, and blowing rales were heard below the clavicle on inspiration. The first heart sound was slightly impure, the second sound muffled at the apex. Over the pulmonic area the first sound was faintly heard, the second was roughened over the aortic area. The radial pulse was regular, easily compressible, and of good volume. There was no enlargement of the liver, the spleen was not pal-There pable. In walking the patient carried the left knee higher and more forward than the right. She did this to carry the foot and toes over the floor, which she was unable to raise independently owing to defective action of the extensor muscles of the foot and toes. She could not move the toes, and there was but slight flexor action of the left foot and not complete in the right. There was no Romberg's sign. Muscular strength was fair in the lower extremities, repeated tests, however, showed rapid exhaustion. The patient had a coarse tremor in both hands which occurred only during volition. The grip of both hands was fair and equal, but muscular strength was easily ex-There was considerable incoordination in the hands and arms after repeated attempts to extend and flex them. The reflexes of the upper extremities were not present, the knee jerks were absent, also the Achillis tendon reflex on both sides and the plantar reflex was not obtained. Other skin reflexes were not active. There was considerable tenderness over the nerve trunks of the extremities. Hyperæsthesia principally of the arms and legs, localizing sense was somewhat disturbed in the toes and feet, loss of sense of position quite marked in the toes of both sides. The stereognostic sense was not impaired. The blood and urine analysis revealed nothing of interest.

On March 7, 1908, the patient was transferred to a surgical clinic and was operated upon by Dr. Nancrede for the removal of the tumor in the right axilla. rapid recovery and returned to her home on June 20th of the same year. Three months after the operation the patient wrote in response to a letter that she had been entirely relieved from the paroxysms of pain in the right axilla and had improved in general health.

Summary.—About two thirds of the cases on record, the total numbering about forty-five, are those of an advanced stage and some with extreme mental and physical debility of long standing. In some of these the physical debility is most marked, in others the psychic phenomena more prominent, while in others the mental faculties are not disturbed even after the disease has existed for years. The accumulation of fat, pain and tenderness in the fatty swellings, and asthenia are constant and characteristic symptoms in the majority of cases recorded.

As ætiological factors in the author's case we find early in life evidence of a marked unstable nervous system. Trauma which figured in a number of cases, was recorded, after which the first symptoms appeared. Disturbance of the sexual organs is frequently mentioned in the records of cases, and was present in this case; also pregnancy during which an exascerbation of the ailment occurred and which finally resulted in abortion at the end of the third month. A case reported by Spiller dated from pregnancy, while Schlessinger and others reported cases following abortion. The menopause seems to be a prominent predisposing cause, and so in the writer's case the patient's symptoms became more marked during this period. Clinically, marked irritability with short periods of apathy were early symptoms. These were prominent in Dercum's cases and were noted early in the disorder. In this case apathy has appeared periodically throughout the course of the disease and of late more frequent. Asthenia is

found mentioned in the records of nearly all of the cases. In this case it was apparent in the attacks of weakness and later the awkwardness in the handling of objects and subjectively the feeling of complete exhaustion, also the easily exhausted muscular strength during repeated muscular efforts. Pain and tenderness were present in all of the cases reported whose records I examined. In the case just reported the pain was rather general at the beginning and did not become paroxysmal until localized accumulations of fat appeared, then the pain was sharp and piercing and more distinctly localized. The disturbances of sensation consisted of paræsthesiæ, the patient having a great deal of numbness, prickling and tingling in the hands and feet; hypæsthesia to touch, pain, and temperature in the arms and legs less marked over the trunk. This has been found in the majority of cases, and numbness is a common complaint. Hypæsthesia of touch, pain, and temperature is the rule. Disassociation is not frequent, although mentioned in two or three of the cases. Vasomotor phenomena are comparatively frequent, especially lessened perspiration. In several cases more marked conditions, such as cyanosis, ecchymosis, and trophic ulcers of the extremities, are recorded. The condition of the reflexes is quite constant, and the reports show that the knee jerks and tendon reflexes in general are markedly depressed or entirely absent. The biceps and triceps jerks, also the knee jerks, and the Achillis reflexes were absent in the writer's case. The skin reflexes could not be elicited.

It is stated by some authorities that paralysis does not occur. This, however, is contrary to the pathological findings in one of Dercum's cases in which the post morten examination showed an interstitial neuritis, and paralysis was present in the left foot of the patient under consideration. This developed gradually, extending over a period of two or three years.

The complete paralysis following a seizure in which the patient's body was in a pose of opisthotonus accompanied by unconsciousness, referred to before, cannot be associated directly with adiposis dolorosa as a part of the symptom complex, but as in many other organic conditions of the nervous system is an expression of a neurotic temperament and frequently manifests itself in such extreme functional distortion, either through the debilitating influence of the organic disease or through some external exciting cause. This is important in the diagnosis, as frequently the symptoms due to an organic change are entirely masked by the functional disorder where hysteria accompanies organic disease.

The gastrointestinal disturbances spoken of in the history of the case have been observed in a number of cases of Dercum's disease and are probably reflex

in origin.

Pathology.—The most constant organic lesion is a change in the thyreoid gland, however the thyreoid gland was normal in one of the cases that came to autopsy. The fatty tissue does not deviate from the normal. In one of Dercum's cases referred to before there was an interstitial neuritis with some sclerosis in the columns of Goll. In three out of five cases examined there was a lesion in the pitutiary body. While the post morten examination in

cases of adiposis dolorosa are rather limited as the disease is rarely fatal and of infrequent occurrence the pathological findings are much the same as those found in acromegaly. Clinically, there is an overgrowth of fatty tissue in adiposis dolorosa, while the same is true of the osseous structure in acromegaly.

Conclusion.—In conclusion I may say that adiposis dolorosa is a neuropathic condition of unknown cause occurring in women with neuropathic heredity, and is characterized by painful, fatty swellings occurring in various parts of the body, which condition is preceded or followed by asthenia. Many other symptoms varying from a slight functional disarrangement to organic degeneration are incidental expressions of an inherited unstable nervous system occurring in many other nervous disorders.

As to treatment, we have no remedy which has given uniform results. The thyreoid extract has given relief in a few cases; in one case an apparent cure was brought about. The removal of the fatty accumulations through surgical means gave relief to this patient for a time at least. She improved in general health, and was free from pain for a considerable period after each operation. However, as the condition is progressive, we may not expect anything but temporary alleviation, recurrence of the fatty swellings, and with this an exacerbation of the symptoms.

REPORT OF THE PROCEEDINGS OF THE THIRD INTERNATIONAL SANITARY CONVENTION.*

By R. H. VON EZDORF, M. D.,

Quarantine, La.,

Passed Assistant Surgeon, United States Public Health and Marine Hospital Service.

Under the Imprimatur of the American Society of Tropical Medicine.

In compliance with a call for the assembling of the Third International Sanitary Convention of American Republics by Dr. Walter Wyman, chairman of the International Sanitary Bureau, dated June 18, 1907, the convention was held in Mexico City, December 2 to 7, 1907, to which thirteen republics sent a total of twenty-three delegates. The Bureau of American Republics also sent a representative.

The meetings were held under the presidency of Dr. Eduardo Liceaga, with Dr. Juan Jose Ulloa, as secretary. These officers had been elected at the previous convention held in Washington in 1905.

The sessions were held in a hall of the Treasury

Department in the National Palace.

The provisional program which was prepared by the chairman of the International Sanitary Bureau, Dr. Walter Wyman, was as follows:

(1) "Each delegate will bring a paper relating to the nation he represents. This paper will cover

the following points:

(a) A report on the existence of transmissible diseases which may prevail in its territory, especially with reference to bubonic plague, cholera, yellow fever, malaria, beriberi, and trachoma. This report will give detailed information on the measures which have been adopted for the prevention or stamping out of any of the diseases above mentioned, if they are unfortunately present in the coun-

try represented by the delegate.

(b) A report on the condition of the ports of his country, specifying the works which may have been executed therein, those in course of construction and those which are projected, as well as the manner in which the problem of water supply, of proper sewerage and of the connection of house drains with that system has been solved, as well as the methods that have been employed or are proposed for the sanitation of dwellings.

(c) A return of the assistance which the general governments may have furnished to the respective states or municipalities, for the execution of sanita-

tion works in the cities and ports.

(d) A report on all the sanitary police laws which have been issued since October 14, 1905.

(2) Every delegate will suggest some practical means to prevent persons who may be suffering from tuberculosis from transmitting the disease to the healthy persons who may be traveling in their company either in trains or in vessels.

(3) As forming part of the order of the day, the delegates will be at liberty to present original papers

relating to the following points:

(a) Studies directed to the discovery of the germ

of vellow fever.

(b) Studies directed to the investigation as to whether there are other means of transmission of vellow fever and malaria besides the sting of the mosquitoes.

(c) Studies directed to the perfection of the

methods of combating the mosquito.

(4) Each delegate will present a report upon the organization in his own country of the commission of three medical or sanitary officers intended to form part of the International Sanitary Commission of Information of the American republics, as provided for in paragraph 3 (b) of the resolutions adopted at Rio de Janeiro.

(5) Report upon the establishment of the Sanitary Information Bureau of Montevideo, as provided in paragraph 3 (c) and paragraph 4 of the

resolutions adopted at Rio de Janeiro.

(6) Report upon the establishment of relations between the International Sanitary Bureau at Washington and the Bureau Sanitaire International of Paris, as provided in paragraph 3 (d) of the resolutions adopted at Rio de Janeiro.

(7) Besides the full papers and reports above mentioned, each delegate will bring an extract of the same, but so concise that it can be read in fifteen minutes. These extracts alone will be read during

the meetings.

(8) All the extracts will be written in Spanish and English. Those presented by the delegates from Brazil will be in Portuguese and English, and those by the delegates from Haiti will be in French and English, so that while each delegate reads his extract in his own language, the others can follow, reading the same document in the language with which they are familiar.."

The first session was held on the morning of December 2, 1907, at 10 o'clock, and was addressed by the vice president of the republic of Mexico,

^{*}Read by title at the fifth annual meeting of the American Society of Tropical Medicine, held at Baltimore, March 28, 1908.

Don RAMON CORRAL. In his address he briefly summarized the work and results obtained by the previous two conventions, and pronounced the work of the present convention and all conventions to come, in formulating principles relating to public health for the adotpion of all nations, a duty to civilization. The spirit of his nation, he said, was to abide by such results as had already been demonstrated by the expenditure of large sums of money and free appropriations for sanitary purposes. He welcomed the delegates to Mexico in the name of the president of the republic.

Dr. Liceaga then welcomed the delegates. He reviewed the work of the previous conferences, stating that the first convention was a congress of hygienists, who expressed their adherence to the advanced position of sanitary science. The second reached an agreement between the nations concerning measures for defense against plague, cholera, and yellow fever. He then asked for the adoption of defensive measures against tuberculosis, malaria, beriberi, and other infectious diseases. The logical method was to prevent diseases from originating in the country itself, and that the ideal method would be to have cities provide good water supply, drainage, sewerage, paving, light, and ventilation, and to prevent the overcrowding of buildings, so that they cannot be invaded by transmissible diseases.

He then reviewed some of the work done in Mexico, particularly with regard to the eradication of yellow fever, which had existed along its Gulf coast for four centuries. The campaign waged against the epidemic in 1903, which had spread as far as the northern frontier, practically eradicated the disease in three months. The succeeding camthe disease in three months. paign to eradicate the latent foci in the states of Tamaulipas, Vera Cruz, and Yucatan, resulted in limiting the disease to five isolated cases in eleven

months.

He then mentioned bubonic plague, which had been eradicated after a campaign of six months following its appearance on the Pacific coast of the

He then said: "I have mentioned these examples in order to demonstrate how great is the obligation under which we all stand to attend to the sanitation of our cities; not only the great centres of population, but also the smallest ones, even the villages.'

He concluded with an axiom for the guidance of all nations of America, "To defend our legitimate interests without injury to ourselves or doing injury

to others."

Dr. O. Gonzales Cruz reported for Brazil. He said that the sanitary conditions of Brazil were improving every year as the result of the campaign waged against infectious diseases. A special organization administered sanitary measures against vellow fever: (1) The isolation of those suffering from the disease and the fumigation of the houses occupied by them. (2) The systematic destruction of mosquitoes. (3) The verification of deaths and medical vigilance over persons not immune residing in the infected centre. In order to prevent the spread of bubonic plague, the extermination of rats, the destruction of fleas, the disinfection of houses, the isolation of cases, the inoculation with antipest serum exas being practised. The use of serum was reported

to have reduced the mortality from this disease fifty per cent. The destruction of mosquitoes in cities and the administration of five grains of quinine every three days were adopted with excellent results for the prevention of malaria. Immigrants who were suffering from trachoma were debarred. Vessels were thoroughly disinfected when beriberi had

Floating plants, completely equipped with disinfecting apparatus, were in operation at Rio de Janeiro and Santos. Other ports, as Bahia, Para, Maranhao, Rio Grande do Sol were to be equipped

with like plants.

The federal authorities contemplated forming a complete sanitary organization of all ports of Brazil. Plans were in preparation for equipping all ports

with disinfecting plants and hospitals.

Dr. J. J. Ulloa reported that important port and sanitary works were in progress in Costa Rica and that the most approved modern sanitary appliances were being introduced.

No plague, yellow fever, beriberi, or trachoma

has been reported.

Malaria prevailed, especially on the Atlantic and Pacific coast regions.

About 72 per cent. of the mortality in Costa Rica occurred in children under five years of age.

The sanitary state of the country with respect to yellow fever had been excellent, owing to the adoption of measures for exterminating the stegomyia

calopus.

Dr. Hugo Roberts gave a detailed account of the sanitary organization of Cuba, which had a National Board of Health. The Quarantine Service enforced laws and regulations which were practically the same as those of the United States, the superior board of health or national sanitary department supervised all matters concerning public health and sanitation in the republic.

He discussed the work of the immigration service and the occurrence of yellow fever in Cuba since its reappearance in November, 1905. No plague had thus far occurred, but some observations were made with a view of determining the distance which rats would swim in Havana harbor. For this experiment six rats were thrown into the bay of Havana and their movements observed. The following observations were made:

(1) Rats are able to remain on the surface of the water for from thirty-five to forty-five minutes.

(2) They do not swim in a straight line

(3) If they happen to see a floating object, they steer for it, seize it, if possible, and hold on unless separated from it by force.

Consequently (1) it is sufficient to anchor the vessel requiring fumigation fifty metres from shore, as rats will not cross this distance unless carried by a current or some floating object.

(2) Floats should be placed near the vessel, so that rats falling into the water may find ready

refuge where they may be easily killed.

The delegates from Chile reported as follows: In Chile matters of public health are entrusted to a Department of the Interior and to the municipal governments.

Whatever public health measures are promulgated by the Department of the Interior, upon advice of the superior council of health and Institute of Hygiene, at Santiago de Chile, are enforced by the intendants, governors, and officers representing the executive in their respective territories. Bubonic plague formed seventy-five per cent. of the cases of plague observed in eight coast cities; the septicæmic or intestinal form gave five to six per cent., and the pneumonic formed one to two per cent.

No yellow fever was reported. Malaria and beriberi were unknown. There had been an extensive epidemic of smallpox. Typhoid fever was endemic.

The delegates from Ecuador reported: The Board of Health of Guayaquil, which is the principal port of Ecuador, is an independent body. It has representatives in all ports, and its jurisdiction extends over five provinces. In enforcing public health measures it has adopted and is guided by the rules laid down by the convention of Washington.

An effort will be made to have congress pass a

law making vaccination compulsory.

A drainage canal is to be built in Guayaquil which will be indispensable for the sanitation of the city in the work of exterminating yellow fever and malaria, which are endemic.

In Quito, the capital city, a sanatorium for tuberculosis is about to be completed, which it is said will rival any institution of its kind in Europe or

America.

Trachoma, beriberi, and bubonic plague are unknown in Ecuador. A quarantine has been established at all ports against places where plague prevails. A quarantine station was established on the island of Puna in 1903, and no expense has been spared in equipping it.

Smallpox in mild form has prevailed among persons not vaccinated, but no epidemic occurred.

For the United States, Surgeon General WALTER WYMAN, Public Health and Marine Hospital Service, reported on the work done by the Hygienic Laboratory of the service in matters of public health, its study of typhoid fever, milk industry, supervision of vaccine and antitoxin production, uncinariasis, and tuberculosis. He submitted reports on the progress of the work of the service in San Francisco for the eradication of plague; on the leprosarium at Molakai, in Hawaii; on the National Quarantine Service, which now has forty-three stations operating since the acquisition of the Gulf port stations; on the Foreign Quarantine Service in the Philippines; the inspection of immigrants, both at foreign ports and all domestic ports in the United States; on mosquito extermination work in Baltimore, and on the sanitary works contemplated and in progress in the cities of Mobile, Galveston, and New Orleans.

The report from Guatemala stated that in May, 1906, a code of health was promulgated, providing for all sanitary regulations and measures based on recent approved methods applicable to the conditions

met in that country.

Malaria prevailed in all sea coast cities. Trachoma and beriberi were said to exist in the country. Only one case of typhus fever was reported in the first six months of 1007.

There was an institute established in the capital city for the production of animal vaccine. Vaccination was compulsory.

A Superior Board of Health had been created for the direction of matters of public health. The government contemplated the erection of sanitary stations (quarantine stations?) at Puerto Barrios on the Atlantic, and at San Jose on the Pacific coast.

Since 1900 Salvador has had a Superior Board of Health. All ports are equipped with disinfecting

apparatus for marine sanitation.

Vaccination and revaccination every six years is done by the government, animal vaccine being used.

Malaria in all its forms is endemic.

Tuberculosis causes six per cent. of all deaths. No epidemic of yellow fever has occurred in Salvador since 1900. Since that date but one case of yellow fever was confirmed and six suspicious cases

reported.

On account of the financial conditions of the country, no extensive works for the sanitation of cities

and water supplies could be undertaken.

Discussion of the measures of the international sanitary policy against yellow fever. Dr. Liceaga reviewed the conditions in Mexico and spoke in favor of permitting persons arriving in good health from suspected or infected ports to land without detention. He said that in Mexico the high officials were admitted without restrictions. Suspected cases of yellow fever were allowed to land and to proceed to such places in Mexico as were known to be unfavorable for the spread of yellow fever. Suspected cases entering infectible territory would be held under observation by local authorities. So far as Mexico was concerned he did not think more stringent measures were necessary or need be applied.

Dr. Guiteras stated that such measures as advanced by Dr. Liceaga would not be applicable to Cuba, where every portion of the country had conditions favoring the propagation of that disease

tions favoring the propagation of that disease. Surgeon General Walter Wyman stated that in the United States we had infectible and noninfectible territory; that while the general conditions in each country forced themselves on the authorities, quarantine measures were about the same for all, and would need to be applied as the necessities arise and circumstances require. It was, therefore, not necessary to take the same measures against a vessel from an infected port in Boston as in our southern territory.

Dr. Cruz stated that isolation was impracticable in his country, and for that reason daily inspections were made of all sick and suspects. As many as

4.000 visits were made in one day.

Discussion on malaria.—Dr. LICEAGA opened the discussion. He said that in Mexico the sanitary forces, now engaged in the work of exterminating yellow fever infection, would be employed to do similar service in the places where malaria prevailed. He proposed that all countries carry on a crusade against malaria in the same manner as was done in tuberculosis.

Dr. GUITERAS stated that the majority of persons detained at Las Animas Hospital, in Havana, on account of fever were found to be suffering chiefly with malarial fever, for which disease they were treated before being permitted to leave the hospital and enter the country. He favored a mild quaratine and introduced resolutions to that effect.

Dr. H. L. E. Johnson proposed that the name

of diseases transmissible by mosquitoes be called "mosquito fever." That malaria be then called "anopheles fever"; yellow fever, "stegomyia fever," etc. This nomenclature, he maintained, would give the people a more accurate notion of the cause of the diseases and would facilitate the work of the sanitary authorities in enforcing preventive measures against the spread of those fevers.

Dr. Ulloa suggested the name "stegomyia mosquito fever," "anopheles mosquito fever," etc., adding the word "mosquito" to the names given by Dr. Johnson. He said that the education of the masses was the first step toward putting down any disease, and they should know the exact causes of diseases.

Dr. Guiteras brought out the fact that in Cuba malaria was not spread solely by anopheles, but also by other species, such as the cellia. He thought that the terms were, therefore, not applicable.

Dr. CRuz stated that in Brazil myzomyia were present.

Dr. R. H. von Ezdorf mentioned his experience at the New Orleans quarantine station during the past summer, where all persons from the tropics arriving with fever were held for observation. It was his experience that nearly all cases excepting about twenty, which were cases of typhoid fever, proved to be malarial fever, chiefly of the æstivoautumnal type. In all cases, however, the parasite or other evidence of malaria was found and demonstrated microscopically. He also favored the detention and quarantine of cases of malarial fever when in the active stage of the disease.

Discussion on the measures of the international sanitary policy against bubonic plague and cholera. -Dr. LICEAGA gave a detailed account of the work done at Mazatlan and emphasized the following

points in the campaign:

(1) Depopulation as far as possible, and notification of authorities at destination. (2) Inoculation of persons with antipest serum. (3) House to house inspection. (4) Hospital for suspected cases. (5) Lazaretto for positive cases of plague and for convalescents. (6) Observation camp for those exposed. (7) Destruction by fire of all houses which cannot be disinfected. (8) Destruction of rats, mice, and fleas. (9) Cordon about the infected town or city.

Dr. CRUZ stated that persons leaving Rio de Janeiro were vaccinated with antipest serum.

Dr. Espiro stated that plague had been in Montevideo in 1901; that cases had been traced to the custom house, where rat plague prevailed; that some cases were traced to bags used in packing crackers, that these bags came from Asuncion. Some cases had been traced to bags used for coffee from Rio.

Discussion on trachoma, beriberi, and other transmissible disease.—Dr. LICEAGA, in discussing the presence of some cases of trachoma and beriberi in Mexico, stated that an immigration law was in preparation providing that immigrants suffering with tuberculosis, scrofula, acute malaria, beriberi, or other transmissible diseases, be prevented from entering the country. He believed that if all nations of America adopted measures for preventing admission of immigrants sick and incapacitated for work, it would contribute materially toward the improvement of hygienic and social conditions.

Dr. Hugo Roberts stated that immigrants suffering with trachoma were not permitted to land in Cuba.

INIW YORK MEDICAL JOURNAL.

Dr. Ferrer, of Chile, stated that out of 17,000 known cases of various forms of conjunctivitis, only 0.14 per cent. were found to have trachoma.

Discussion on measures for preventing the transmission of tuberculosis in railroad cars and ships.— Dr. Liceaga opened the discussion on this subject and mentioned the use of metallic plates heated by electricity or other means for burning the expectoration. That on railroad cars a special place might be provided with a vessel or receiver where the passenger could go to expectorate, and where the spittle would be carried off by a current of water or destroyed in situ by heat. Pocket spit cups were to be used only in special cases.

Dr. Hugo Roberts, of Cuba, favored the application of prophylactic measures to vessels as well as to cities. Vessels should be looked upon as floating hotels, and frequent disinfection should be done.

Dr. FERRER, of Chile, favored the use of envelopes for napkins when not frequently changed, to

avoid contact of napkins after use.

Dr. R. H. von Ezdorf said that it was impossible to take extraordinary measures, that whatever regulations were adopted must be easy of application. The following measures were practicable:

1. Physical examination of crews before giving

employment.

2. The traveling public should be educated to understand that the practice of expectorating promiscuously might be dangerous and was filthy.

3. Notices should be posted enjoining passengers not to expectorate on floors. Receptacles should be provided for this purpose. Paraffined spit cups, which were cheap, should be provided.

4. All persons should be encouraged to use indi-

vidual drinking cups.

5. Living quarters of short trip vessels to be disinfected periodically; long trip vessels should have the steerage quarters disinfected at the end of each

6. Screening as far as practicable of the galley, dining rooms, and living quarters, to prevent the

access of flies.

Dr. Soza, of Chile, recommended the following measures

1. Avoid the use of carpets in dormitories.

2. Spittoons to be well distributed.3. The disinfection of cars and berths.

3. The disinfection of daining rooms, envelopes for 4. The disinfection of dining rooms, envelopes for the part changed frequently. napkins when the latter are not changed frequently. 5. The examination of passengers and the isola-

tion of suspected cases of tuberculosis.

Dr. H. L. E. Johnson, of the U. S., recommended that tuberculous subjects be not employed on cars or ships where, in the discharge of their duties, they would come in contact with passengers. That they be not employed as porters, cooks, or dining room attendants; the education of the people; the destruction of flies; separate apartments for tuberculosis subjects, and disinfection of berths and

Sanitation of ports and cities.—Dr. LICEAGA presented a paper on the sanitary work done, such as providing water supply, sewerage, drainage, and paving in the principal cities of Mexico, on the assistance afforded by the federal governemnt. A total of over \$45,000,000 was appropriated by the government for Tampico, Vera Cruz, Coatzacoalcos, Manzanillo, Salina Cruz, and Mexico, D. F. The amounts appropriated for the cities were in addition to sums appropriated by the states and cities themselves for carrying out the work required.

On a motion made by Dr. Espiro, of Uruguay, the delegates voted unanimously a rising congratulatory vote to Dr. Liceaga and the Mexican Board of Health in acknowledgment of the sanitary work

accomplished by them.

Dr. Juan Guiteras read a paper in which he gave a history of the spread of yellow fever and the campaign made against yellow fever in Cuba

since its reappearance in November, 1905.

Respecting an improvement in the methods for exterminating the mosquitoes he mentioned the plan by which large dwellings with their patios are completely covered with a tent and then fumigated. He said that this plan was working satisfactorily.

Dr. LICEAGA stated that a canvas cover, in sections, is used in covering *jacals* and thatched houses to make them air tight preparatory to fumigation. The canvas sections overlapped each other when applied and the ends were fastened to the ground, so that there would be no space for a mosquito to escape.

The following resolutions were approved by the Advisory Committee and were passed by the con-

vention:

I. The representatives of the governments of Brazil, Colombia, and of Uruguay are asked to adhere to the sanitary convention which was signed

in Washington in 1905.

2. To the American governments represented in this convention is recommended the codifying of all sanitary laws and regulations of the respective countries, and as soon as this is accomplished, to forward copies of them to the International Sanitary Bureau at Washington.

3. The convention is recommended to authorize the International Sanitary Bureau of Washington to establish by means considered by them to be most convenient, corresponding relations with the international sanitary bureau of Paris, in accordance with the declaration made by the third Pan American Congress, held in Rio de Janeiro, August, 1906.

4. That the secretary be authorized to include in the publications of the proceedings of the third international sanitary convention a summary of all the resolutions adopted by the first and second inter-

national conventions held in Washington.

5. That recommendations be made to the American governments of the convenience of agreeing upon compulsory vaccination against smallpox.

6. That recommendations be made to the governments represented in this convention of the convenience of declaring free from state taxes the salts of quinine, fine wire, mosquito netting to be used as a protection against mosquitoes, crude petroleum, mosquito bars, and material used for that purpose.

7. That recommendations be made through the medium of the respective authorities that the governments enter into a most active propaganda on

the ætiology, prophylaxis, and treatment of malaria, and resolve upon the establishment of public conferences on these subjects in schools, shops, barracks,

8. That recommendations be made for the establishment of centres at necessary points for the free distribution of quinine to the poor in necessary

quantities for the prophylaxis of malaria.

9. That recommendations be made to the governments that they order the maritime sanitary authorities to include in the public health reports which they issue the mortality occasioned by malaria.

10. That recommendations be made to the International Sanitary Bureau at Washington that it give information to the countries represented of the ex-

istence of malaria at the principal seaports.

11. That recommendations be made to all governments alike for the publication of a pamphlet in which is compiled in a brief, simple, and practical form, easily understood by the public, facts concerning malarial fever, for liberal distribution.

12. That recommendations be made to the governments that they prohibit the immigration of per-

sons suffering from trachoma and beriberi.

13. That recommendations be made to the various American nations for the legal and adequate steps in favor of the nationalization and centralization of sanitary authorities.

14. That to the American governments be recommended the following suggestions for the prevention of tuberculosis in railway cars and steamships:

a. To avoid, as far as possible, the use of carpets

and fixed curtains.

b. To recommend the use of spittoons well distributed.

- c. Periodical disinfection of cars and staterooms, including furniture, beds, washbowls, linen, etc. These disinfections should especially be made in the third class passenger quarters. All clothing, including napkins, should be disinfected before being washed.
- d. Disinfection of dining room service and the use of paper envelopes or covers for napkins used by passengers; also that food be covered with screens; that doors and windows of railroad cars, staterooms and habitations on vessels be screened with fine wire netting to avoid the introduction of flies.
- e. The examination of employees of passenger trains and vessels, in order that tuberculosis subjects

are not employed.

f. All vessels should have a special and comfortable department for the accommodation of tuberculosis patients, its construction not to admit of the retention of dust in any part.

g. The pasting of notices in public places con-

demning the habit of spitting on floors.

h. Recommending that physicians on board a vessel be not only titled in their profession, but, if possible, to have a special knowledge of the prophylaxis of tuberculosis.

15. That recommendations be made that it would be advantageous for the European nations to adopt the Sanitary Convention of Washington of 1905 for the colonies they have in America.

16. That recommendations be made to the Amer-

ican nations that it would be advantageous to have a uniform bill of health, and that such contain the

same class of information.

17. That recommendations be made to the American governments that it would be advantageous to establish separate hospitals for the treatment of tuberculosis, and if such is not possible, then the establishment of separate wards in hospitals for the treatment of such sick.

Costa Rica was chosen as the place of the next International Sanitary Convention of American Republics, to assemble December 25, 1909.

Dr. J. J. Ulloa was elected president.

The social features included banquets, a tea at Chapultepec Café, a visit to Chapultepec Castle, where the Mexican band rendered music, a reception by President Diaz, automobile rides, and excur-

A visit to the penitentiary proved of interest. The penitentiary occupies 32,700 square metres. Entering the administration building, the delegates were shown the administrative offices. In one room was the anthropological department, where skulls of all persons executed at this penitentiary were collected and preserved. All data concerning the individual skulls was kept on cards and a comparative study could be made with the normal skull by any one interested.

Entering the prison grounds proper, the first thing that attracted the attention was a central steel tower thirty-five metres high. This tower supported the water tanks and served as a watch tower where guards were continually on duty, and from which a perfect view was had of all parts of the prison.

The prison was said to be planned after the Irish or Crofton penitentiary system. The buildings, seven double rows of two story structures divided into cells, were built radiating from the tower.

There were two central bath houses, each built in the form of a circle, located in the prison courtyard. In the centre of each bath house was a small tower, from which a full view was had of the twenty-three individual bathrooms into which this space was divided by walls as radiating from a centre. Each individual bath or compartment was furnished with a stone wash tub, stone closet seat and closet, shower and stone bath tub.

As each prisoner entered a compartment he was locked in, and the watchmen in the tower could see that he took his bath. When the prisoners completed their baths and were ready to leave, the watchman took them through a series of setting up exercises, giving the signal and marking time for the various movements by striking a club on the rail in front of him. No prisoner could see the other, but all went through the exercises with clocklike regularity.

The water supply for the prison was from five artesian wells giving 500 litres of water per minute.

The plumbing system for sewerage and drainage was modern and of approved pattern. Toilets were

flushed automatically.

The delegates were also shown the hospital, autopsy room, schools, work shops where shoes were made, carpentry and cabinet work done, palm leaf weaving, etc. Other points of interest shown were the bakery, kitchens, mess halls, steam laundry, electric lighting plant, etc.

At the disinfecting plant all disinfecting apparatus were displayed and shown by the corps of disinfectors, all of whom were uniformed. The following is a list of apparatus shown:

Formaldehyde vaporizing apparatus; vacuum apparatus, a form of hand pump and tank provided with a hose and an attachment for going over carpets, walls, etc., for taking up dust, by which process, it was stated, sixty-six per cent. of microorganisms were removed; bichloride pump and sprays; apparatus for the safe production of hydrocyanic acid gas; a portable steam chamber; wagon, zinc lined, for bringing infected clothing to the central plant, etc.

The central plant was furnished with two chambers of the Fernand Dehaitre type, made in Paris. One was for washing and boiling clothing, the other for steam disinfection at high pressure. A partition wall completely separated the two ends of this apparatus. One room had its special entrance for receiving infected clothing to be placed into the chamber at that end. The clothing when disinfected was removed at the other end of the chamber, which

opened into a room on the other side of the partition

Rabies department. The laboratory rooms for the production of virus and for the treatment of hydro-

phobia were then shown us.

For the production of virus the first inoculation was made from a brain brought from Paris in January, 1888; animal inoculations had been made since that time. The virus caused death of the inoculated rabbit on the seventh day.

A subdural inoculation into a rabbit was made at the time of the visit; an autopsy on a rabbit which had just died was made, removing the whole spinal cord and showing the technique for making the preparations.

Since April, 1888, to November 30, 1907, the following number of persons were treated:

rabies 518 Persons inoculated by animals probably rabitic Persons inoculated by animals suspicious of rabies 3,457

Persons inoculated by animals known to have

Total A register giving a history and other data of each individual treated was kept. There were twentyeight persons under treatment at the time of the visit, Dcember 4, 1907.

Water supply for Mexico City. There were several sources of supply, but a new one now under construction from Xochimilco was visited.

The first point seen was the site for four reservoirs. The reservoirs were constructed of cement, with cement columns to support the cover, which was to be topped with a grass lawn.

A cement tunnel encasing a stout wire net tunnel of expanded metal would be the conduit from the source of water supply located near Xochimilco.

Sewerage system. The sewer flushing pump station was visited. A map showing the sewer mains throughout the city and their termination into the

Grand Drainage Canal was explained.

The pumping station had steam and electric pumps for forcing water, 1,500 litres per second, through the sewers for the purpose of flushing them,

which was made a daily service.

The sewerage system was that known as the "combined water system," comprising 1, sewers for collecting house refuse and rain water; 2, flushing pipes and pumping station; 3, main collecting sewers which discharged all waters into the Grand Drainage Canal and thence out of the valley through Tesquisquiac tunnel.

The sewer pipes were so arranged as to admit of thorough flushing, there being no blind ends where stagnant water could remain. Ventilation was provided and sewers made accessible through manholes.

The General Hospital. This hospital comprises sixty-four buildings and was constructed on the pavilion plan. Thirty-two buildings had hospital wards; seventeen were for general service, as fol-lows: Porters' house, office of administration, residence for physicians, disinfection station, electric plant, machinery, stables and carriage house, hydrotherapeutics gymnasium and electrotherapy, operating rooms, and morgue; ten other buildings were for watchmen, and five for attendants to the various infectious wards.

There was to be a school for nurses under the

direction of two German trained nurses.

Visit to the new suburbs, Juarez, Roma, and Condesa. These suburbs were real estate projects, and the plans for starting such suburb must be approved by the government. Previous to permitting the erection of any buildings, streets must be laid out and paved with asphalt, sidewalks of cement, sewer and water pipes laid, and lighting provided.

THE RESISTANT BREATHING TRACT. By W. H. FITZGERALD, M. D.,

Hartford, Conn.,

Laryngologist to St. Francis's 'Hospital.

The father of a large family, most of whom I was treating for ear and throat affections, once asked me: "Why is it my children are so afflicted?" told him it was largely due to the fact that his children had been mouth breathers; to which he replied: "Nonsense, I have been a mouth breather more than forty years and I am perfectly sound." I noted evidences of a familiar difficulty in his breathing, distinctly audible across a large room, and asked him if he had not suffered from asthma, he answered: "Yes, for years to a slight extent." I convinced him that was a result of mouth breathing his children would avoid now that their nasal organs were in form, if taking my advice they breathed at all times as Nature intends they should.

Mouth breathing is ever sure to affect, to a greater or less extent, at least one section of the breathing and accessory tracts, and so it is when one is asked why it is that all mouth breathers are not afflicted with pulmonary tuberculosis, one must answer that some are more susceptible in that particular section of the breathing tract than others; that the mouth breather never goes throughout life

with an absolutely normal breathing tract; that the lungs are only a part of the breathing tract; that some section or sections of this tract must, sooner or later, become affected; it may be but one nostril or one ear, or a section of the pharynx or larynx, or a section of but one lung; it may be the entire breathing and accessory tracts, and failure to breathe as Nature intends we should is largely responsible for these conditions.

If in our crusade against pulmonary tuberculosis we place normal breathing at the top of the list of means of resistance, instead of at the bottom, where it is usually found, if not neglected altogether, and this, I am sorry to see, is too often the case, we will soon stamp out pulmonary tubercu-

We are told that the white plague is to be a thing of the past, and doubtless it will be, but at the rate we are now going and with the present inadequate methods of procedure even the youngest of us will never witness its demise. I have often wondered since the fight against this much dreaded disease commenced how many have been its victims who might now be enjoying good health had they known, that for the preservation of health, normal breathing is at least one of the most important of Nature's laws.

I maintain, without fear of intelligent contradiction, that faulty breathing is responsible for the vast majority of affections of the breathing and accessory tracts, that to breathe through the nose is the only correct way to breathe, and this if properly followed will make not only the breathing and accessory tracts, but the ecenomy generally, resistant

to a degree otherwise impossible.

Normal breathing alone is not any more a panacea for all ills than is a well regulated digestive apparatus or any other of Nature's requisites to good health, but if normal breathing in the future is not reckoned with to a greater extent than it is to-day, we had best throw the idea of stamping out

the white plague to the winds.

Parents must understand that their child to enjoy perfect health must sleep with his mouth closed, must breathe through the nose at all times; and what is true in this regard for the child is true for the parents. If one cannot breathe through the nose, the difficulty, whatever it may be, must be remedied, and nasal breathing must then be insisted upon, the patient wearing the plaster mouth guard as I have advised, at least during sleep, taking breathing exercises, etc., as recommended, until he becomes a normal breather.

If parents would be as attentive to the breathing tract of the child as they are already to his bowels, we would in a very few years see the last of pulmonary tuberculosis as well as most other diseases, and physicians if they will give this very important suggestion a few moments' consideration will surely appreciate it, and parents generally after a little

instruction will appreciate it also.

As I have suggested, I am not advocating nasal breathing as a panacea for all ills, but as a valuable adjunct to that end. We all realize that it would be quite impossible for man to enjoy perfect health if he were not daily mindful of his bowels, for instance, or if he were not equally careful concerning indiscretions in eating or drinking, or, again, if he neglected to protect himself with proper clothing against the inclemencies of the weather, or resisted fresh air and sunshine, etc., etc. It is the duty of all medical practitioners, whatever their field in medicine, to consider these essentials and to impress their patients with the importance for health's sake, of ever living up to them, but in most of my papers and letters these facts are taken for granted, and I have purposely written little other than the necessity of breathing normally.

Concerning the breathing tract, what should parents further understand? They should understand that the nose, as well as being an olfactory organ, is a filter, that it heats or cools, as the case may be, inspired air; that the nose secretes several ounces of fluid daily; that this fluid, which is germicidal, evaporates into the air respired, assuring a moist and resistant breathing tract, provided

the individual is not a mouth breather.

If through some indiscretion, as perhaps the continuous wearing of damp clothing, especially stockings, or neglect of the bowels, any section of the breathing tract of the nasal breather becomes congested, it will be found that the condition responds much more readily to treatment than it would in the case of the mouth breather similarly affected.

Parents should further understand that it is not possible to properly aerate the lungs other than with air inspired through the nose, that one can expand his chest from one half to one and one half inches more inspiring through the nose than through the mouth, that the breathing capacity is necessarily increased, also the fact that chapped and fissured lips are usually caused by alternating currents of cold and warm air respired through the mouth; and that infected teeth and gums are usually those which have become dry due to mouth breathing. Practically all infections of the mouth and pharynx are confined to those who breathe to a greater or less extent through the mouth. That a closed mouth is ever moist should be remembered always; whether the secretions of the mouth are normal or not depends upon the general conditions of the breathing and digestive tracts.

When we reflect, therefore, that faulty breathing is largely responsible as well for nearly all so called catarrhal conditions of the upper breathing tract, for the majority of middle ear difficulties, for a large percentage of eye trouble, to say nothing of innumerable affections of the rest of the economy, it occurs to me that we should warn, not only the medical profession, whom we have repeatedly warned during the past seven years, but also nonmedical members of society engaged in one of the most commendable of projects, namely, the attempted obliteration of the white plague—that they are not doing their full duty unless they endeavor to make absolute nasal breathing a universal practice. In so doing they are not only fighting pulmonary tuberculosis along rational lines, but practically every other disease man is heir to as well.

Whether or not the child is a nasal breather is one of the very first observations a teacher should make on the first appearance of the little one at school. If he breathes with difficulty or is unable to breathe at all, appropriate treatment should be concluded before he is received into the school. Children already in advanced grades who are in like manner afflicted should be appropriately treated and instructed, and this same advice holds good in the case of teachers, who must, in the not very distant future, practise what they will be asked to teach, namely, normal breathing.

The elocution or vocal teacher who tells one it is not possible for a pupil to take practically every breath through the nose should be convinced that intelligent nasal treatment and instruction will

make it possible.

When this fact is generally appreciated the gasping-performance so common to-day of numerous so called singers and elocutionists will be relegated to the past. The vocalist or public speaker will through normal breathing protect his breathing apparatus and preserve his voice as he would otherwise be unable to do so.

904 MAIN STREET.

A CASE OF GENERALIZED XANTHOMA PLANUM IN A CHILD.

By Robert Abrahams, M. D., New York.

Two features make my case unique in dermatological affections: First, the age of the patient; second, the universal distribution of the lesion.

CASE.—The child, Harry K., three and a half years old, of Russian parents and born in New York City, was brought to the skin service of the Gouverneur Hospital Dispensary by my assistant, Dr. Louis Bernstein, in the month of May, 1908. There was nothing of importance in

the family history.

The child's history was as follows: At the age of two and a half years he had scarlet fever. During the period of desquamation, to quote the boy's father, "small, pin point pimples appeared here and there over the body. The pimples after awhile flattened and became yellow. In a short time more of the same kind appeared and kept on coming," until the day of presentation the eruption covered every part of the body except the scalp and mucous membranes. The chin, neck, upper and lower extremities, both extensor and flexor surfaces, thorax, abdomen, groins, and gluteal region, including the cleft of the nates, were the seat of hundreds of small and large citron yellow patches, some flat, some slightly raised at the edges, smooth to the touch, and all typical of xanthoma planum, as seen in adults on the upper and lower eyelids. The eyelids and upper parts of both cheeks were free from the lesion, contrary to the usual distribution of the disease. The largest of the patches were found around the nates and anus. A few good sized ones were to be seen on the deltoids, the largest patch is the size of a cent and the smallest that of a lentil. There were no subjective symptoms. There were no constitutional or local disturbances at the time of appearance of the xanthoma. The urine was repeatedly examined with negative results. The child was well nourished and was in the best of health.

The microscopical examination of the skin is yet to be made, as at present the parents are opposed to an "operation."

Some day I may succeed in adding the pathological findings to this clinical report.

It may be stated in conclusion that the child was presented to the Manhattan Dermatological Society October 2d with complete unanimity of diagnosis.

43 St. Mark's Place.

Our Beaders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXIX.—How do you treat sick headache? (Closed

October 15, 1908.)

Cather 16, 1908.)

due not later than December 15, 1908.)
Whoever answers one of these questions in the manner receive a prize of \$25. No importance whatever will be at-tached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not REQUIRED) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

address, onto or which we must be at thority to publish.
All papers contributed become the property of the Jounnal.
Our readers are asked to suggest topics for discussion.
The prize of \$25 for the best essay submitted in answer to question LXXVIII has been awarded to Dr. Charles
Floyd Burrows, of Syracuse, N. Y., whose article appeared

on page 842.

PRIZE QUESTION LXXVIII.

THE TREATMENT OF ACUTE CORYZA.

(Continued from page 895.)

Dr. Robert E. Coughlin, of Brooklyn, N. Y., observes:

Improper elimination appears to be the cause of acute coryza, as near as one can judge from the fact that preceding the attack there is generally a history of overeating, constipation, or irregular action of the bowels, inactivity of the skin, with a little overactivity of the kidneys showing the increased strain put upon them.

The treatment I advocate in this condition resolves itself into forced exercise, sweating, and the

cold plunge.

To order my form of treatment the patient of necessity must be free from any organic or constitutional disease.

No local treatment is required, as it is my experience that local treatment only throws the inflammation down into the larynx or the bronchial tubes.

When the first symptoms are noticed, which generally occurs the first thing in the morning on arising after a night of unrefreshing sleep, one should advise eating very sparingly. Milk, bread, and the breakfast foods will be found sufficient. Tell your patient he must devote one day to the treatment and make up his mind to undergo rather heroic means without the use of drugs. In the first place he must dress himself as warmly as possible in good weather or the reverse. Heavy underclothes; sweater; heavy soled shoes (preferably old and with rubber heels); well fitting socks or stockings without seams; a warm cap or hat; heavy suit of clothes, and if in winter a short overcoat. A five mile run and walk is in order, walking along the sidewalk and running

across the streets. This distance should be covered in one hour's time. A light stick or cane will assist in giving the proper swing to the walk, which is The walking should be at top speed. One will find that a mile in twelve minutes may be averaged without extreme fatigue. The slowest mile will probably be the first and the best the last. city blocks are equal to a mile, so one can figure on a city map just the distance to be covered. The destination should be a turkish bath in winter and a bathing beach during the months of June, July, August, September, October, and possibly a part of November. The patient should remain from a half to one hour in the hot room of the Turkish bath with the temperature 145° F. He should drink just enough water to quench his thirst and no more. After shampoo he must take a cold shower and plunge, alternating between the steam room and the cold plunge, 60° F. Then he should finish his bath with a cold shower as cold as the water runs, and should cool off in the cooling room and dress very slowly. He must be careful not to perspire any more the rest of the day. Coming away from the bath he should walk a few blocks and remain indoors in an even temperature of about 72° F for the rest of the day. Upon awaking the following morning the patient will feel refreshed after a night of very refreshing sleep. There will be no laryngitis or bron-chitis present. The bowels will act better for this treatment and no medicine, as a rule, will be required. Less urine will be passed for a few days and a general feeling of well being will be present. The most important part of the treatment, I believe, is the forced exercise, as the Turkish bath itself will not accomplish the same result. The exercise with the cold plunge either in the sea or ordinary bathtub will answer very well, but the best treatment is the combined light diet, forced exercise, Turkish bath, and the cold plunge or shower. No acute coryza should last over one day when Nature's treatment is instituted.

The trouble with this form of treatment (and it is the only one) is that it is difficult to make our patients understand that it is not necessary to take drugs. They do like to drug, and we as physicians are to blame for this to a great extent. At times it is a little trying to get them to take the exercise, but this is less trouble than the dispensing with drugs. A placebo may be given at times, but it is hardly necessary when once the patient's confidence in the treatment is established. The easy treatment, such as hot drinks, drugs internally and locally, hot bath upon going to bed, etc., appeal to many patients, but the one word elimination should ever be in our mind in the treatment of this annoying ailment.

Dr. Walter G. Heriman, of Brooklyn, N. Y., remarks

The treatment of this condition, better called a symptom, is both prophylactic and active. As it is generally a terminal symptom following an infection of the nasal or adjacent passages, treatment to be successful must be instituted early, that is, before the mucous passages have become occluded.

Under prophylactic measures may be mentioned the wearing of silk or woolen underclothing during the entire year, especially in a climate like that of

New York city, as witness the last week in August of this year. Another factor which merits recognition is the constant irritation of the nasal passages by steam radiators, found in poorly ventilated houses and offices. This condition is best met by the daily application of an oily spray containing either oil of eucalyptus or menthol. Keeping the skin active by baths, etc., and sleeping with an open window at night should be encouraged; and above all, protective footwear should always be insisted upon, especially in persons easily chilled or afflicted with some form of nasal catarrh. Should there be any nasal defects present, such as a deflected sæptum, spurs, hypertrophied turbinates, adenoids, or polypi, they should receive appropriate surgical treatment. Under active treatment the tincture of aconite in gtts. 1/2 doses every two hours, repeated five to six times, will frequently relieve or moderate the congestion, thereby shortening the duration of the attack; to obtain the best results it must be given early. Some physicians prefer tincture of veratrum viride, but I think the former safer and equally efficient. either of the foregoing may be added the spirit of nitre, or the solution of ammonium acetate, thereby improving diaphoresis. The well known Dover's powder, gr. x, and quinine sulphate, gr. v, may be given at bedtime, followed by a warm drink (lemonade, whiskey, etc., according to the individual's particular scruples); this applies especially to business men who will not remain at home, and followed next day by a capsule containing acetphenetidin, gr. vii; monobromated camphor, gr. i; and quinine sulphate, gr. i; every three hours. Should the fulness over the forehead be severe, the quinine may be omitted. Should the patient be greatly annoyed in breathing, an application of adrenalin or cocaine to the nasal mucosa will often be of service.

The nasal chambers should be frequently sprayed with either Dobell's or Seiler's solution, followed by an oily spray of oil of eucalyptus and menthol, the latter being soothing and cooling, for which the

patient is often very grateful.

It must be remembered that the upper lip is frequently irritated by the nasal discharge; it is therefore advisable to suggest the application of cacao butter to the same. Steam inhalations of compound tincture of benzoin or oil of eucalyptus, a drachm of either to a kettle of hot boiling water, covering the head, save the face, will often relieve the tension markedly.

A saline purge should always be given, as it tends to drain the body fluids away from the congested area. Turkish baths may be suggested, provided there is no cardiac contraindication; while footbaths

should always be insisted upon.

As this condition is not always limited to the nose, the throat and the bronchial tubes may often be simultaneously involved; for the former the various gargles containing either potassium chlorate, boracic acid, fluid extract of hamammelis, etc., will often prove valuable. While the bronchitis is best treated by the relaxing expectorants in the early stage, ammonium chloride, syrup of ipecac, syrup of squills, substituting the stimulating expectorants in the later stages, the secretion being profuse, ammonium carbonate, syrup of senega, etc.

Many of these cases the physician never sees, in

fact the majority, the laity being bound by time honored family traditions to play the physician, bringing into requisition that great pacifier, the family medicine chest.

Dr. Lester R. Mellor, of Syracuse, N. Y., states:

As coryza is a congested condition of the Schneiderian membrane associated with more or less congestion of the mucous membrane of adjacent and contiguous structures and is therefore purely a vasomotor change in the mucosa in which there is dilatation of the superficial arterioles and capillaries, the ideal treatment would be to give such drugs, internally and locally, as would tend to reduce congestion and put the mucosa in a normal state. General treatment consists in so reguating the circulation as to diminish blood supply to this part by causing a general superficial dilatation of the capillaries of the body. In other words, an attempt to overcome the local vasomotor conditions. This is accomplished by the use of aconite in M 1/2 doses every one half hour for five to six doses, followed at bedtime by a hot mustard footbath or general bath, hot lemonade, and Dover's powders, grs. x. Patient is to cover up well to encourage a free diaphoresis, as this is most beneficial. This active treatment will terminate many beginning coryzas, but is of little use if the condition has existed for any length of time. Nevertheless, I have seen it do some good even in these

Locally the following will be found most useful: I, Cleansing nasal cavities with some alkaline solution. 2, Spraying cavities with adrenalin I in I0,000 in saline solution. This contracts the capillaries, blanches the surface, and lessens the discharge. As this action is but temporary, I use an oil spray composed of camphor and menthol, āā grs. x; in benzoinol, āi; sprayed on to a nasal mucosa. This gives membrane a coating of oil, the camphor and menthol exerts a cooling, anæsthetic effect upon the turgescent membrane, lessens the discharge, and keeps the nasal cavity free.

Dr. Max Baff, of Worcester, Mass., says:

Acute coryza is an inflammatory affection of the upper part of the air passages resulting from catching "cold," and is attended by a discharge from the nostrils and congestion of the mucous membranes of the eyes, nose, and throat.

The attack usually commences shortly after catching cold, more particularly after exposure to dampness and cold, and begins with a feeling of indisposition, sense of cold down the back or general chilliness, sense of weight in the forehead, headache, especially frontal, and drying of the nares and throat. This is what I call the stage of congestion, and it is during this time that we are sometimes able to abort the attack.

Treatment during this stage of the disease is to endeavor to remove the congestion from the head, and therefore our aim must be to cause a congestion of some other part of the body and thus remove the blood from the head. Hence have the patient place the lower extremities up to the knees in water, as hot as can be borne, containing a quantity of powdered mustard (about an ounce to each gallon of water) and to keep them in the water for at least

one hour—until the feet and legs assume a scarlet color.

An adjunct to this treatment in this stage is to secure additional congestion of some other part of the body, and this is easily obtained by having the patient take several glasses of very hot lemonade while soaking the feet as above described, and to take a saline laxative just before retiring.

The stage of congestion, if not aborted, will in a few hours be followed by the stage of mucous secre-

tion

In this stage there is present a discharge from one or both nostrils, watering of the eyes, pains in the face, soreness of the throat, and sometimes hoarseness, together with a dull aching pain all over the body. The treatment during this stage is mainly symptomatic. The patient must remain in the house till the disease entirely disappears, for complications are very likely to occur in this stage.

A powder containing acetphenetidin, gr. v, and calomel, gr. i, with or without sugar of milk, may be given every two hours until six are taken. This is the dose for an adult who has a sound heart.

The running of the nose is the chief discomfort that brings the patient to the doctor, and therefore it is up to the physician to combat this distressing This can best be accomplished symptom at once. by local treatment. Many doctors use snuffs containing morphine and bismuth subnitrate. I do not believe in snuffs, because I think, and also find, that the snuff will lie on top of the rapidly secreted mucus and not conme in contact with the mucous membrane. Therefore I recommend and use fluids, and the best solution to apply locally to the nostrils by a nebulizer is a two per cent. solution of cocaine. The frequency of the applications will depend upon the amount of discharge and nasal occlusion present. The cocaine instantly relieves the "blocking up" of the nares caused by the swollen mucous membrane, by removing the congestion, thus stops the secretion of mucus, and makes the breathing normal.

Atropine given internally will dry up the secretions of the nose, eyes, and throat, but then the patient will suffer from dryness of the larynx and bronchi and from constipation, etc.; in other words, it does as much harm as it does good. Camphor, menthol, opium, and the like are all very nice, theo-

retically, but practically do no good.

Dr. George Stevenson, of New York, writes:

A patient in the early stage of an acute coryza should take a hot foot bath, with mustard in it. He should go to bed, take two grains of calomel, in divided doses; Dover's powder, 5 or 10 grains, followed by a hot lemonade. The Dover's powder may be repeated in four hours if the patient is awake. The patient should be kept well covered, there should be no draught in the room, and the temperature of the well ventilated room should be kept at about 65° F. In the morning the patient should take one half bottle of magnesium citrate. This will often cure the patient in this stage.

During a later stage of an acute coryza, when the mucous membrane and tissues of the nose are swollen, soggy, and ædematous with exudation, the office practice is to apply a four per cent. solution of co-

caine to the nostrils by means of an atomizer, followed in five minutes by a cleansing wash, used in an atomizer, such as a diluted Dobell's solution, one part to five parts warm water. This should be followed by a spray containing menthol, gr. viii; camphor, gr. v; petrolatum fl, 3i. At home the patient may use the dilute Dobell's solution, followed by the spray of menthol, camphor, and petrolatum, every four hours.

Internally the patient should take a tablet con-

taining:

| 3 | Atropine sulphate,,gr. 1/600; |
|----|--------------------------------|
| | Strychnine sulphate gr 1, 240; |
| | Arsenous acid,gr. 1/240 |
| | Morphine sulphate,gr. 1/100; |
| | Quinine sulphate,gr. 1/10; |
| | Powdered camphor,gr. 1/4. |
| М. | S. Every four hours. |

If the patient comes for treatment having a profuse serous or mucopurulent discharge, the treatment should be cleansing and stimulating to the mucous membrane, and the patient should be given 2 to 4 grains of quinine sulphate three times a day.

The prophylaxis consists in avoiding climatic inequalities; dressing too warmly; having room excessively hot or cold; chest protectors, mufflers, etc.;

heavy overshoes.

If patient has polypi, deformed sæptum, or any form of obstruction to free nasal breathing, this must be corrected by proper surgical measures.

Dr. Samuel Moskowitz, of New York, remarks:

Acute coryza, otherwise known as acute rhinitis or acute cold in the head, is one of the most common conditions we see, not so much as medical men, but more as laymen. Everybody has it or has had it, but very few go to a physician for it.

At the onset of the trouble it begins by stuffiness of the nose, due to tumescence of the mucous membrane; then the best thing I have found in my practice is to take the same evening a hot drink, either tea or lemonade, sweetened to the taste, and a pow-

der containing:

When the bowels are irregular add to this prescription I grain of calomel. This usually causes a good deal of perspiration, and it is advisable to tell the patient to cover himself well. This is to be repeated the next night.

For its local action I find an excellent remedy in compound tincture of benzoin, 5i, to six glasses of boiling water, the steam to be inhaled three times daily. In a good many cases the powder prescribed

has acted almost specifically.

If after three days of this treatment there is no relief, which is quite uncommon except in those cases in which the patient is out and about, being exposed to changes in temperature, I prescribe:

| \mathbf{R} | Pulv. camphoræ,gr. ½; |
|--------------|--------------------------------|
| | Ext. beliadonnæ,gr. 12; |
| | Pulv. ipecacæ et opii,gr. iii; |
| | Quininæ sulphatis,gr. i. |
| | Fnt. chart. No. xx in caps. |
| Sic | One every three house |

oig. One every affect hours.

This relieves the extreme rhinorrhœa and the watering eyes, and also the slight cough which there may be.

As soon as the patient gets relief from the discharge from the nose, the capsules may be then taken three times or twice daily as indicated.

In all cases, where practicable, the patient should

be indoors and warmly dressed.

In the stubborn cases and those cases in which I elicit a previous history of rheumatism, I combine with the capsules salicin, gr. v to x.

Prophylaxis, after attack, is to see whether the patient has hypertrophied turbinates, sinus disease, adenoids, amygdalitis, etc., and have these treated

properly.

Sprays in the nose I have found useless, except where sleep is impossible on account of the stuffiness in the nose. I prescribe here a solution of adrenalin chloride, I in 5,000, to be used in an atomizer, at night. If we have bodily rest in these cases we accomplish a great deal.

(To be concluded.)

Therapeutical Rotes.

Scopolamine-Morphine and Chloroform Anæsthesia.—In Folia Therapeutica for October, 1908, Dr. H. Macnaughton Jones describes his method of administering scopolamine-morphine and chloroform to obtain anæsthesia, as follows: On the night before the operation (which takes place at 9:30 next morning, 1/100 grain of scopolamine and 1/6 grain of morphine are injected the last thing. On the morning of the operation this injection is repeated at 7 o'clock, after the bowel has been freely and thoroughly emptied. At 8:30 a. m. an injection of 1/100 grain of atropine and from 1/36 grain to 1/60 grain of strychnine is given; sometimes the atropine is omitted. The chloroform is administered by the Vernon Harcourt regulator.

Blackening of the Tongue by Hydrogen Dioxide.—Attention has been directed by M. L. Bizard (Les Nouveaux remèdes; The Lancet, October 31, 1908) to the phenomenon of black tongue as caused by the use of hydrogen dioxide as a mouth wash. He cites the case of a smoker who used a mouth wash daily for eight days consisting of a tablespoonful of hydrogen dioxide in half a glassful of warm water. A marked blackening was then found on the dorsal surface of the tongue, but on ceasing to use the mouth wash the coloration disappeared in a few days. The patient was in good health, except that an examination of the tongue showed that the lingual papillæ were hypertrophied. The same effect was produced in the case of two patients undergoing mercurial treatment by the injection of grey oil, who were in the habit of rinsing the mouth with hydrogen dioxide. It was at first thought that the color was due to the action of the hydrogen dioxide on the mercurial saliva, but hydrogen dioxide alone, as has been shown, may produce the same effect. It is remarked by the editor of The Lancet that, as hydrogen dioxide has now come into general use as a mouth wash, these observations are of great interest and value. Apart from the blackening of the tongue, which may result from too free a use of this preparation, the question arises whether the general em-

ployment of antiseptic mouth washes and dentifrices is advisable in healthy persons. Where decay is known to exist there is no doubt that a moderate use of antiseptic agents tends to prevent the spread of the invading organisms. But when the mouth is in a healthy condition it would seem preferable to rely upon cleanliness rather than on antiseptics. The bacterial flora of the mouth may contain organisms that naturally tend to preserve it in a healthy condition, but the continued use of antiseptics is calculated to destroy favorable as well as harmful bacteria.

The Treatment of Gout.—The specific remedy for painful gout is colchicum. As an application to the painful parts the following liniment on warm cotton is recommended in *La Clinique* for October 23, 1908:

The liniment should be mixed with an equal quantity of hot water and applied on absorbent cotton to the affected part, the whole being covered with oiled silk. The application is renewed every four hours.

On the second day of the attack the following mixture is prescribed for internal use:

| \mathbf{R} | Tincture | of | colchicum flowers, | |
|--------------|----------|----|---------------------|--|
| | | | digitalis, | |
| | | | fraxinus ornus, | |
| | | | cinchona, | |
| | | | belladonna, | |
| | inchure | of | olycyrrhizingtt. xx | |

M. et Sig.: Add one teaspoonful to four tablespoonfuls of water, and take one teaspoonful of the mixture every hour.

The dose should be diminished as the condition of the patient improves, and the medicine should be stopped entirely by the time sweating becomes profuse and diarrhoea sets in.

Treatment of Ulcerated Sore Throat.—Moure (La Clinique, September II, 1908) employs the following as a gargle, a teaspoonful of the solution being added to a glassful of lukewarm water:

| \mathbf{R} | Antipyrine, | | | |
|--------------|-------------|------|------|------------|
| | Resorcin, . | | | 3iss; |
| | Sodium be | | | |
| 3.5 | Glycerin, . | | | 3vi11. |

The following is recommended for use in an atomizer:

| \mathbb{R} | Morphine hydrochloride,gr. 3/4 to gr. iii; |
|--------------|--|
| | Phenol crystals,gr. viiss; |
| | Cocaine hydrochloride,gr. viss to gr. xv; |
| | Menthol,gr. xv; |
| | Glycerin, |
| | Distilled water, |
| Annua A | |

Dissolve the menthol in a small portion of alcohol, filter, and add the remaining ingredients.

Another prescription for the less painful forms of ulcerated sore throat is the following:

| 1≩ | Cocaine hydrochloride,gr. vi | iiss ; |
|----|------------------------------|--------|
| | Antipyrine, | |
| | Sodium bromide, | |
| | Spirit of peppermint, | cxv; |
| | Glycerin, | iss; |
| | Distilled water | ixvi. |

The spray should be administered three or four times a day before meals.

Under Domestic Postage Rates, \$5; under Foreign Postage Rate, \$7; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail. Entered at the Post Office at New York and admitted for trans-portation through the mail as second class matter.

NEW YORK, SATURDAY, NOVEMBER 14, 1908.

PROFESSOR MACCALLUM'S HARVEY LECTURE.

A number of commonly accepted ideas regarding fever are apparently without scientific foundation. according to Professor W. G. MacCallum. there is no greatly increased heat production, not nearly so much, for example, as follows active muscular work. And there is no considerable burning of the tissues. One of the main factors in the production of fever appears to be a disturbance in heat regulation, though there is also a moderate increase in oxidation processes and therefore in heat production.

It was astonishing to learn from Professor Ewing, who introduced the lecturer, that this was practically the first scientific presentation of the nature of fever made in New York since 1886, when Professor Welch took that as the subject of his Cartwright lecture. The very definition of the term fever is one of great difficulty, despite the fact that thousands of physicians use the word correctly many times daily. According to MacCallum, fever may be considered to be a reaction to a variety of injuries, characterized by a moderate increase in heat production, by changes in temperature regulation, and by changes in metabolism.

A study of fever at once brings us face to face with the interesting fact that the temperature of birds and mammals is almost independent of their environment, and is kept fairly constant. When the enormous difference which often exists between the

animal temperature and that of the environment is considered, we must marvel at the wonderful mechanism by which this constancy is maintained. There seems to be some general control of this function in the brain, although, according to MacCallum, the thermoregulating centre is not yet clearly established. It is not known whether the centre is affected directly by the temperature of the blood which bathes it, or whether it merely responds to nerve impulses from the periphery. Experiments on animals indicate that certain areas of the anterior portion of the corpus striatum lodge a heat centre.

In speaking of the normal temperature of animals, the lecturer spoke of the regular daily variation. It is astonishing to learn that in crows the fluctuation may amount to as much as 3° F. Some years ago this phase of the subject was studied by Benedict, who found regular daily variations also in man, though not so large as that just mentioned. He also found that the variations occurred at the same times, even when the daily routine of the persons was inverted so that they worked at night and slept by day. Even though the amount may not be very great, it is of the highest interest to know the source of the increased heat production. This is an intricate problem, and it is still not entirely solved. According to MacCallum, the main source first drawn upon is the stored carbohydrate (the glycogen), then the fat is used, and finally the proteid of the tissues. Experiments have also shown that the administration of carbohydrates in considerable quantities has a sparing action on the tissues. Gelatin appears to have a similar effect.

Certain figures presented by the lecturer regarding the amount of heat production by man under various conditions give a good idea of the need of food in fever. Thus, the amount of heat produced by an ordinary man, kept perfectly quiet, may be represented by twenty-one grammes of carbon dioxide hourly; it is higher after a meal, and highest after strong muscular exertion, amounting to 125 grammes or more. In a number of febrile conditions the figures were as follows: In erysipelas, thirty-six grammes in an hour; in pneumonia, thirtythree grammes; and in typhoid fever, twenty-one grammes. This would appear to bear out Lewis's contention that in typhoid fever the amount of food required is extremely small, for example, not much more than a pint of milk a day.

An interesting suggestion, though not a novel one, made by the lecturer was to the effect that the rise of temperature in the body had some beneficent action, affecting, for example, a destruction of the toxines producing the fever. On the other hand, nothing was said of the probable injurious effect produced by the temperature on various organs. We know that a cold sponge bath profoundly alters the mental condition of our patients in typhoid fever or pneumonia. Yet it is improbable that the sponging has any direct influence on the poisoning. It would have been interesting to learn what effect hydrotherapy and antipyretic drugs have on the febrile process. We know what happens to the temperature, but how about the other changes, the heat production, regulation, metabolism, etc.?

In studying the cause of aseptic fever, for instance, after severe surgical operations, Arthur Mandel found that there was a considerable increase in the excretion of the alloxuric bases, and that this increase quite generally paralleled the course of the temperature. At the same time there is a diminution in the excretion of uric acid, so that he rightly considers that there is an interference with the oxidative powers of the cells. That these xanthin bases were really productive of fever was shown by administering strong decoctions of coffee, which, of course, contained caffeine, trimethylxanthin. This produced a rise of temperature to 100.3°, which persisted for several hours. it has been shown that tuberculous patients may excrete considerably increased amounts of the purin bodies, Mandel suggests that these liberated purin bases may have a decided influence on the febrile temperatures observed in tuberculous disease. Is it possible that the outdoor life effects a more complete oxidation of these bodies, and thus reduces the amount of poisoning of the system?

Altogether, the speaker presented a great mass of data, most of which were exceedingly technical and not easily followed by his auditors. If we do not misunderstand the objects of these Harvey lectures, the results of the latest achievements in various departments of science are to be presented to physicians in broad outlines readily grasped. Medicine has grown to such vast proportions that even intelligent physicians cannot hope to do more than secure a clear general idea of what is going on in other departments than their own.

MEDICAL PRACTICE AND THE CHURCH.

A notable discussion has appeared recently in one of the newspapers, the New York Times, on the merits of the quasimedical activity of the Rev. Dr. Worcester, of Boston, and the Rev. Dr. Batten, of New York, each the rector of an Episcopal church. Ordinarily we deprecate the discussion of medical matters in the newspapers, for the medical contributors are apt to speak "over the heads" of general readers; and the lay commentators are prone to speak with an assurance born of profound ignorance. In this instance, however, the subject is

one that can readily be understood by educated persons who have not had a medical training, and we look upon it as eminently fitting that its consideration should have been taken up in a popular publication.

Up to the present time, the chief contributors to the discussion have been Dr. Joseph Collins, Dr. I. Leonard Corning, and Dr. M. Allen Starr. All these gentlemen are professed neurologists, and it is particularly to the neurological point of the medical circle that the Emmanuel Church "movement" is tangent. Dr. Collins opened the discussion in a letter to the editor of the Times. The tenor of Dr. Collins's letter was deprecatory of the "movement." It is impossible to deny the truth of the greater part of Dr. Collins's contentions, but we may rise above their pessimism. In particular, it may be remarked that Dr. Collins underrates the activity of the Episcopal Church in the establishment of hospitals and kindred institutions for the relief of the sick and injured in New York; St. Bartholomew's Clinic is by no means the sole or even the chief manifestation of that activity—witness, to mention only one, our magnificent St. Luke's Hospital. He appears also to ignore the immense medical work done under the auspices of the Church of Rome, the Presbyterian Church, the Methodist Church, and other Christian bodies, besides the Jews in their religious rather than in their racial capacity.

Dr. Corning's contribution is in the shape of an interview. In the main he sustains Dr. Collins's contentions, but with admirable conciseness of expression. He also points out forcibly some of the evils which may result from the movement, drawing his arguments largely from the consequences of similar movements in the past. Dr. Starr's letter rather favors the movement, though with such reservations that it appears to us that he has struck the juste milieu. As regards our own impression, we do not see in the movement anything subversive of the prerogatives of medical men in their daily work; the ecclesiastics, as represented by Dr. Worcester and Dr. Batten, seem to us to stand ready to cooperate with the medical profession, and not in the least disposed to antagonize it. As we understand them, the reverend gentlemen are disposed to the utmost to "render unto Cæsar the things that are Cæsar's."

THE PRIEST AND THE DOCTOR.

In pursuance of the subject dealt with in the preceding article, one of the wardens of St. Mark's Church, Mr. John Brooks Leavitt, in a letter published in the *New York Times* for November 9th, states that the medical profession and the clergy have "drifted into such antagonism that doctor and parson too often glare at each other over a dying

bedside, each regarding the other as an intruder, the clergyman thinking the doctor to be godless, and the latter looking on the former as a simpleton." This statement cannot have been founded on any very great array of facts, and surely, whatever an unregenerate doctor might do, a clergyman would refrain from glaring, though Mr. Leavitt charges the glaring to the two impartially.

What is the truth of the matter? To those who may be ready to admit that Warden Leavitt depicts a condition sufficiently general to give rise to serious concern we commend a sermon entitled The Relations of the Priest and the Physician, by the Rev. Arthur B. Conger, of Rosemont, Pa., published in this issue of the Journal. It is true that Mr. Conger says: "Please do not leave orders that we are to be excluded from the sick room." The general tenor of his sermon, however, makes it a safe inference, we take it, that priests are seldom excluded by the physician's direction from the bedside of persons seriously ill. Certainly it is very rarely that there can be any justification for thus excluding them, though there are instances in which a man may suppose himself to be at death's door, but erroneously. In a few of those instances the advent of a clergyman may confirm the sick man in his fears and actually turn the scale against his

In the generality of cases, we believe, the physician welcomes the priest, provided he comes at the proper time, and Mr. Conger quotes Dr. Mitchell (meaning Dr. S. Weir Mitchell, we presume) as having recently said that "the physician who in cases where a certain moral mandate was to be impressed upon the patient has never sought the aid of the clergyman must have missed some valuable assistance." Mr. Conger is careful to add that he entirely concurs in the opinion of one of our most distinguished physicians that "when a suggestion has to be made to a hypnotized subject it had better be made by a doctor than a priest."

We believe that there is great mutual regard of priests and physicians for each other. It comes out often in speeches by clergymen at medical banquets and in the almost invariable opening of important medical meetings with a prayer by a clergyman invited for the purpose. This regard of the clergy for physicians was further shown recently in an address, entitled Some Thoughts on the Medical Profession, delivered by the Very Rev. Dr. Joseph S. Glass, president of St. Vincent's College, at the opening of the present annual session of the College of Medicine of the University of Southern California and published in the October number of the Southern California Practitioner. "The physician, the teacher,

and the priest," says Dr. Glass, "—their object is to further the interests of humanity. No individual can afford to dispense with the services of any one of these three." It is surely true that cooperation rather than repulsion is manifested whenever the priest and the physician meet at the bedside of the sick. And so may it ever be.

AN AUSCULTATORY SIGN OF TWINS.

It seems that in their antenatal existence twins need not be possessed of "two hearts that beat as one," quite as two horses harnessed in a span do not necessarily trot in perfect unison. Indeed, it is upon this absence of exact synchronism, compared by him to the slightly irregular tread of the two horses, that M. M. E. Arnoux (Journal de médecine de Paris, October 3d) founds a new auscultatory sign of twin gestation. The sounds of the two feetal hearts, he says, are to be heard in their greatest intensity in the neighborhood of the mother's median line, rather nearer to the pubes than to the umbilicus. It is the lack of unison that establishes the presence of twins.

PALATABLE PREPARATIONS OF THE BROMIDES.

Practical pharmacists will be interested in the announcement from the Craig Colony for Epileptics, at Sonyea, N. Y., that a prize of \$25 will be awarded to the person who devises the best method of masking the taste of the bromides in a solution containing not less than ten grains of potassium or sodium bromide in a teaspoonful dose, and without impairing the value of the drug in any way. Contestants for this prize may send their formulas to Dr. W. P. Spratling, Sonyea, N. Y. The use of potassium or sodium bromide in continuous doses in the treatment of epilepsy appears to be a necessity, and the great difficulty is to present the drug in some palatable form, as patients acquire a great dislike to the taste of the salt after a prolonged period of use. Simple solutions of the bromides in water also cause gastric irritation, and numerous have been the means tried to prepare the drug in some form that would not repel by its taste or exert a disturbing effect on the stomach.

A Florentine physician has devised a method of preparing a fifty per cent. solution of potassium bromide which is suitable for hypodermic use, and it is frequently found necessary to administer the drug in this way in order to obtain quick results. To a three ounce solution of potassium bromide Dr. R. Rebizzi adds thirty grains of sodium sulphate and fifteen minims of carbolic acid, each of these

drugs being credited with a specific action. The carbolic acid is said to act as a local anæsthetic and at the same time maintain the sterility of the solution, while the sodium sulphate is supposed to facilitate absorption and favor the elimination of the carbolic acid. The combination seems an excellent one from a theoretical point of view, but we question whether injections of such a solution, directed, by the way, to be driven deep into the front part of the thigh, would be well borne if given oftener than once or twice a week. There is a suggestion here, however, for intending contestants for the prize offered by Dr. Spratling.

Obituary.

WALTER R. GILLETTE, M. D.,

of New York.

On Saturday, November 7th, in the sixty-eighth year of his age, Dr. Gillette died in the Roosevelt Hospital, of malignant disease of the intestinal tract, an affection which for many months had been sapping his bodily powers. Although he was a native of Philadelphia, practically all his life had been spent in New York. He was a graduate of the College of Physicians and Surgeons, of the class of 1862. He practised medicine in New York for several years, and lectured on obstetrics in the Medical Department of the University of the City of New York. He then became connected in a professional capacity with the Mutual Life Insurance Company as a coadjutor of the late Dr. Gustavus S. Winston. After serving the company for a number of years as a medical officer, Dr. Gillette was transferred to the business department and became the company's vice-president. In that capacity he showed himself exceedingly capable, but when the management of the life insurance companies of New York was recently made the subject of popular criticism and official investigation, Dr. Gillette was among those who suffered. Eventually, however, he was virtually exonerated by the Supreme Court, and it is certain that those who knew him intimately never doubted that he was innocent of the offenses charged against him. He was, indeed, an amiable and upright man.

Rems Atems.

Changes of Address .- Dr. M. Grant McGinnis-Jones, to 166 West One Hundred and Twenty-ninth Street. New

The Society of Physicians of Canandaigua, N. Y .-- A meeting of this society was held on Thursday, November 12th. The programme included a paper on Air as a Thera-

peutic Agent, by Dr. A. M. Mead.
Dr. Osler Not Elected.—The official announcement of the vote for the Lord Rectorship of Edinburgh University shows that Mr. George Wyndham received 826 votes, Mr. Winston Churchill 727 votes, and Dr. William Osler

Sleeping Sickness Commission.—Captain Percival Mackie, of the Indian Medical Service, has been selected by the Government of India to join this commission, which recently left England for Uganda, under the aus-pices of the Royal Society, and under the direction of Colonel Sir David Bruce, F. R. S., R. A. M. C.

The Society of Medical Jurisprudence, New York .--At the two hundred and sixteenth regular meeting of this society, which was held on Monday evening, November 9th, Dr. Robert T. Morris read a paper entitled A New Prospective Era of Medicine.

Royal College of Surgeons Opens a Wider Field for Women.—Resolutions have been adopted by the Royal College of Surgeons of England admitting women to examinations for the diploma in public health, licensure in dental surgery, and the fellowship.

dental surgery, and the fellowship.

A Tablet to the Late Dr. Carroll.—A bronze tablet to the memory of the late Dr. James Carroll was unveiled on Wednesday, November 11th, in the main building of the University of Maryland. Dr. William H. Welch, of Baltimore, delivered the principal address.

Rochester, N. Y., Academy of Medicine.—A regular meeting of this section was held on Wednesday evening, November 11th, under the auspices of Section II. The principal feature of the programme was a paper by Dr. Roswell Park, of Buffalo, entitled Some Recent Aspects of the Cancer Problem.

Medical Society of the County of Orleans N. V.

Medical Society of the County of Orleans, N. Y .-At the annual meeting of this society, which was held recently in Albion, N. Y., the following officers were elected: President, Dr. Charles Fairman, of Lyndonville; vice-president, Dr. George Post, of Holley; secretary and treasurer, Dr. John A. Dugan, of Albion.

Richmond, Va., Academy of Medicine and Surgery.—

A regular meeting of this academy was held on Tuesday, November 10th. A paper on Surgery in Tuberculosis was read by Dr. R. Tunstall Taylor, of Baltimore, and a paper

read by Dr. R. Tunstall Taylor, of Baltimore, and a paper on Surgical Affections of the Biliary Tract was read by Dr. A. Murat Willis. Dr. A. L. Gray opened the discussion.

The Madison County, N. Y., Medical Society.—At the annual meeting of this society, which was held recently in Oneida, N. Y., the following officers were elected: President, Dr. Charles H. Perry, of Oneida; vice-president, Dr. R. H. Ash, of Canastota; secretary, Dr. George W. Miles, of Oneida; treasurer, Dr. S. J. Wilson, of Oneida.

The Montreal League for the Prevention and Treatment of Tuberculosis.—A building, situated in the heart of the city, to be used for dispensary purposes, has been presented to this league by Lieutenant Colonel Burland, of Montreal. Colonel Burland has also made a gift of \$10,000

Montreal. Colonel Burland has also made a gift of \$10,000 to the league, on condition that it raises an endowment of a similar amount.

Franklin District, Mass., Medical Society.-The reguriankin District, Mass., Medical Society.—The regular bimonthly meeting of this society was held at Greenfield, Mass., on Tuesday, November 10th. Dr. Charles Moline, of Sunderland, read a paper on Tetanus, and reported two cases. Infantile Paralysis was the subject of papers read by Dr. C. L. Upton, of Shelburne Falls, and Dr. C. C. Messer, of Turners Falls.

The Medical Society of the Borough of The Bronx held a stated meeting on Wednesday evening, November 11th. Dr. John B. Huber read a paper entitled Modern Methods of Diagnosis in Tuberculosis and their Comparative Value, and Dr. William Loughran read a paper on Some Phases of Tuberculosis in Children. Officers for

1908 were nominated at this meeting.
Syracuse, N. Y., Academy of Medicine.—The following papers were read at a meeting of this academy which was held on Tuesday evening, November 10th: Cretinism —Result of Six Months' Treatment, and the presentation of the patient, by Dr. W. H. Maynard; Fracture—Discocation of the Shoulder, by Dr. D. M. Totman; Long Continued Infection in a Case of Appendicitis, by Dr. C. F.

Anniversary Address at the New York Academy of Medicine.—Major Charles Lynch, of the Medical Corps of the United States Army, late representative of the Medical Corps of the Army in Manchuria, will deliver the amiversary address at the New York Academy of Medicine on the evening of November 19th. The subject of the address will be Medical Service in a Modern Army in War as Exemplified by the Japanese Army in the Russo-Japanese

Infectious Diseases in Chicago.—During the week ending October 31, 1908, there were reported to the Department of Health 630 cases of infectious diseases, this being an increase of 74 over the preceding week. Of the being an interest of 74 over the precenting week. Of the total number of cases reported, 214 were of diphtheria, 177 of scarlet fever, 22 of measles, 16 of chickenpox, 23 of pneumonia, 87 of typhoid fever, 7 of whooping cough, 1 of puerperal fever, 72 of tuberculosis, and 11 of diseases of minor importance.

Philadelphia County Medical Society.-The Central Philadelphia County Medical Society—The Central Branch of this society met on Wednesday evening, November 11th. Dr. W. T. Dugan read a paper on The Uses and Abuses of Electricity in Medicine. Dr. F. R. Starkey read a paper on The Early Diagnosis of Carcinoma of the Stomach. Dr. Barton Cooke Hirst read a paper on the Operative Technique of Complete Laceration the Perinaum

New York Pathological Society.—The regular meeting of this society was held at the New York Academy of Medicine on Wednesday evening, November 11th. Dr. Francis Carter Wood reported a case of Adenomyoma of the Round Ligament; Dr. Herbert L. Celler reported a case of Gastrointestinal Pseudoleuchæmia; and Dr. Warfield T. Longcope, director of the Ayer Clinical Laboratory, Philadelphia, presented a study of cases of Hodgkin's Disease

Lymphosarcoma

The Health of Pittsburgh .- During the week ending October 31, 1908, the following cases of transmissible dis eases were reported to the Bureau of Health: Chickenpox. 12 cases, o deaths; typhoid fever, 29 cases, o deaths; scarlet fever, 48 cases, 2 deaths; diphtheria, 25 cases, 2 deaths; measles, 16 cases, 1 death; whooping cough, 1 case, 1 death; pulmonary tuberculosis, 23 cases, 10 deaths. The total deaths for the week numbered 153, in an estimated population of 565,000, corresponding to an annual death rate of

14.08 in 1,000 population

The Philadelphia Medical Examiners' Association.-At a stated meeting of this association, which was held on Tuesday evening, November 10th, the following papers were read: Mental Diseases from the Examiner's Standpoint, by Dr. Charles W. Burr; Relation of Brain Diseases to Life Insurance, by Dr. T. H. Weisenburg; Relation of Spinal and Vascular Diseases of the Nervous System to Life Insurance, by Dr. Daniel J. McCarthy; Func-tional Nervous Diseases with Relation to Life Insurance, by Dr. Charles S. Potts

Buffalo Academy of Medicine.-At a meeting of the Section in Pathology, which will be held on the evening of Tuesday. November 17th, the programme will include a paper on Darier's Disease ending in Multiple Skin Cancer, by Dr. Grover W. Wende; and a paper on Cancer and Sarcoma, by Dr. H. D. Walker, of Newburgh, N. Y.

A regular meeting of the Section in Medicine was held on Tuesday evening, November 10th. The principal feature of the programme was a paper by Dr. William C Krauss entitled The Postoperative Prognosis of Spinal

Cord Tumors.

Personal.—Dr. Frederic Brush, of Boston, has been appointed superintendent of the New York Postgraduate Medical School and Hospital. Before assuming his duties, however, Dr. Brush will devote some time to a study of postgraduate instruction and hospital administration in American medical centres several

Dr. William Osler has received leave of absence from Oxford University for one year, which he will spend on

the Continent.

Dr. Mazyck P. Ravenel, of Philadelphia, was recently appointed professor of bacteriology at the University of Wis-

Scientific Society Meetings in Philadelphia for the Week Ending November 21, 1908: Monday, November 16th.-Medical Society of the Woman's

Hospital.

Tuesday, November 17th.—Dermatological Society; Academy of Natural Sciences; North Branch, Philadelphia County Medical Society.

WEDNESDAY, November 18th.—Section in Otology, College of Physicians; Franklin Institute; Association of Clinical Assistants, Wills Hospital.

THURSDAY, November 19th.—Section in Ophthalmology, College of Physicians; Section Meeting, Franklin Institute: Southeastern Medical Society; Northeast Branch,

Philadelphia County Medical Society.
Friday, November 20th — American Philosophical Society.

Friday, November 20th—American Philosophical Society.

The Philadelphia Polyclinic and College for Graduates in Medicine.—The following are registered at this college: Dr. Albert Woomer, of Snyders, Pa.; Dr. Mortimer H. Jordan, of Birmingham, Ala; Dr. H. Moore Mace, of Catskill, N. Y.; Dr. Robert W. Dunlap, of Washington, Pa.; Dr. Alden B. MacDonald, of Sugar Grove, Pa.; Dr. C. F. Berwatz, of Pittsburgh, Pa.; Dr. H. J. Stockberger, of Greensburg, Pa.; Dr. B. A. Beale, of Driftwood, Pa.; Dr. C. Wilson, of Ithaca, N. Y.; Dr. F. J. Walz, of Pittsburgh, Pa.; Dr. Claud N. McKee, of Scott-

dale, Pa.; Dr. William Hertz, of Allentown, Pa.; Dr. W. P.

dale, Pa.; Dr. William Hertz, of Allentown, Pa.; Dr. W. P. Sawyer, of Nevada City, Cal.; Dr. William P. Orr, of Lewes, Del.; Dr. J. C. Brown, of Williamsport, Pa.; Dr. S. S. Smith, of Leesburg, Fla.; Dr. Leslie M. Westfall, Of Kansas City, Mo.; Dr. B. F. Miller, of Nampa, Idaho; and Dr. Anna M. Dunn Gordon, of Belaspore, India.

White River, Vt., Medical Society.—A meeting of this society will be held at the Junction House, White River Junction, Vt., on Tuesday afternoon November 24th. The programme will consist of a "symposium" on tuberculosis, and the various phases of the tuberculosis problem will be dealt with as follows: History of the Disease, by Dr. D. R. Chase; Report of the Tuberculosis ease, by Dr. D. R. Chase; Report of the Tuberculosis Congress of 1908, by Dr. William T. Smith; Feeding, Climate, Rest, etc., by Dr E. E. Deane; Home Treatment, Offmate, Rest, etc., by Dr. E. E. Drakt, Thombook by Dr. E. J. Fish; Sanatorium Treatment, by Dr. D. S. Drake; Surgical Treatment, by Dr. J. M. Gile; Spread and Restriction, by Dr. A. C. Bailey; Practical Conclusions, by Dr. O. W. Sherwin.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the De-partment of Health for the following statistics of new cases and deaths reported for the two weeks ending November 7, 1908:

| | ()c | 1. 31- | | |
|--------------------------|--------|---------|--------|-----|
| | Cases. | Deaths. | Cases. | |
| Tuberculosis pulmonalis | 431 | 134 | 443 | 147 |
| Diphtheria | 321 | 21 | 291 | 16 |
| Measles | | 3 | 137 | 6 |
| Scarlet fever | | 6 | 143 | |
| Smallpox | | | | |
| Varicella | 81 | | 91 | |
| Typhoid fever | 85 | 19 | 5.3 | I 2 |
| Whooping cough | | 4 | 9 | 3 |
| Cerebrospinal meningitis | 9 | 5 | 5 | 2 |

Philadelphia Pædiatric Society .- The regular meeting of this society was held on Tuesday evening, November 10th. Dr. Theodore Le Boutillier exhibited several pa-tients with hereditary syphilis. Dr. A. P. C. Ashhurst reported a case of gastrostomy for impermeable stricture reported a case of gastrostomy for impermeable stricture of the œsophagus, and two cases of herniotomy for strangulated hernia in infants. Dr. J. H. McKee and Dr. J. H. Jopson reported three cases of imperforate rectum and anus, with operation. Dr. A. J. Kilmer read, by invitation, a paper entitled A Study of Blood in Pertussis. Dr. W. N. Bradley reported a case of congenital heart disease in an infant, and exhibited specimens. Dr. John Speese exhibited specimens from a case of congenitate hydronenbrosis. tal hydronephrosis.

Monthly Statement of Mortality of the State of New Jersey.—During the month ending October 15, 1908, there were reported to the Bureau of Vital Statistics 2,904 deaths from all causes. Of the total number of deaths 1,047 deaths from all causes. Of the total number of deaths 1,047 were of children under five years of age. The principal causes of death were: Typhoid fever, 34 deaths; measles, 1 death; scarlet fever, 18 deaths; whooping cough, 21 deaths; diphtheria, 34 deaths; malarial fever, 3 deaths; tuberculosis of the lungs, 248 deaths; tuberculosis, other than that of the lungs, 50 deaths; cancer, 144 deaths; cerebrospinal meningitis, 24 deaths; diseases of the nervous system, 351 deaths; diseases of the circulatory system, 307 deaths; diseases of the respiratory system (pneumonia and tuberculosis excepted), 129 deaths; pneumonia, 125 deaths; infantile diarrheea, 367 deaths; diseases of the digestive system (infantile diarrhœa excepted), 225 deaths; Bright's disease. 104 deaths; suicide, 35 deaths; all other causes, 594 deaths

Vital Statistics of New York .- During the week endvital Statistics of New York.—During the week ending October 31, 1908, there were reported to the Department of Health of the City of New York 1,166 deaths from all causes, as compared with 1,355 for the corresponding period in 1907. The annual death rate in 1,000 of population was 13,75; the death rate in the corresponding week in 1907 was 16.49. Of the total number of deaths 325 were of children under five years of age. There were 40 deaths from contagious diseases, I death from malarial diseases, 4 deaths from whooping cough, 134 deaths from pulmonary tuberculosis, 5 deaths from cerebrospinal meningitis, 18 deaths from bronchitis, 144 deaths from diarrheal diseases, 69 deaths from pneumonia, 70 deaths from bronchopneumonia, 16 deaths from suicide, death from homicide, and 61 deaths from accidents. There were 126 still births during the week. Six hundred and fifty-one marriages and 2,261 births were reported during the week.

The Pathological Society of Philadelphia held a stated meeting on Thursday evening, November 12th. tion to a number of card specimens presented by Dr. A. G. Ellis, Dr. C. B. Farr, Dr. John Speese, Dr. A. O. J. Kelly, and Dr. Howard T. Karsner, the programme included the following papers: Experimental Studies upon the Vitality and Virulence of the Tubercle Bacillus when Submerged in Water, by Dr. Randle C. Rosenberger; The Pathogenesis of Spontaneous Cerebral Hæmorrhage, by Dr. A. G. Ellis; The Types of Cerebral Hæmorrhages. with specimens illustrating the various types, by Dr. D J. McCarthy.

The Medical Association of the Greater City of New York.—A stated meeting of this association will be held in Du Bois Hall, New York Academy of Medicine, on Monday evening, November 16th, at 8:30 o'clock. The programme will be as follows: I. Presentation of specimens and cases, and voluntary communications—II. A paper on Asiatic Cholera, by Dr. William H. Thomson.—III. Notes on the Bacteriology of Cholera, by Dr. Edward K. Dunham.-IV. A paper entitled Cholera in its Relation to Comnerce, by Dr. William T. Jenkins, formerly health officer of the Port of New York.—V. Discussion, to be opened by Dr. John B. Huber. The first of the special borough meetings of this association will be held in The Bronx on Mon-day evening, December 7th. Full particulars of the meeting will be issued later.

The Mortality of Chicago.—During the week ending October 31, 1908, there were reported to the Department of Health 541 deaths from all causes, as compared with 510 during the previous week and 508 for the correspond-510 during the previous week and 508 for the corresponding week in 1907. The annual death rate in 1,000 of population was 13,09. Of the total number of deaths 108 were of children under one year of age; 53 of children between one and five years of age; 35 of persons between five and twenty years of age; 217 of persons between twenty and sixty years of age; and 128 of persons over sixty years of age; and 128 of persons over sixty years of age; The principal causes of death were: Apoplexy, 15 deaths; Bright's disease, 45 deaths; bronchitis, 8 deaths; consumption, 54 deaths; cancer, 32 deaths; convulsions, 1 death; diphtheria, 15 deaths; heart diseases. convulsions, I death; diphtheria, 15 deaths; heart diseases 44 deaths; intestinal diseases, acute, 51 deaths; nervous diseases, 19 deaths; pneumonia, 58 deaths; scarlet fever, 14 deaths; suicide, 7 deaths; typhoid fever, 6 deaths; violence (other than suicide). 31 deaths; whooping cough, 2 deaths; all other causes, 149 deaths.

The Tri-Professional Medical Society of New York.
The twentieth stated meeting of this society will be held at the Hotel Astor, New York, on Tuesday evening, November 17th, at 8:15 o'clock. Cases and specimens will be presented as follows: Multiple Fracture of the Inferior Maxilla, by Dr. William J. Lederer; Gangrene of the Vulva, by Dr. Ross McPherson; Intestinal Obstruction complicating Extrauterine Pregnancy, by Dr. John M. Keyes; Fracture of the Tibia and Fibula, by Dr. Augustin H. Goelet; Radiographs of Unusual Injuries to the Shoulder Joint, by Dr. George M. MacKee. Dr. William I. Lederer will read a paper entitled The Relationship between Certain Systemic, Dental, and Buccal Disturbances, and among those who will take part in the discussion of this paper are Dr. D. B. Freundlich, Dr. W. D. Tracy, and Dr. G. M. MacKee. The Practical Value of Tincture of Iodine and Iodine Catgut in Major Surgery is the subject of a paper which will be presented by Dr. Walter T. Dannreuther. Dr. Augustin H. Goelet, Dr. G. K. Dickinson, Dr. G. Morgan Muren, and Dr. John M. Keyes will participate in the discussion.

New York and New England Association of Railway Surgeons.—The eighteenth annual meeting of this association will be held at the New York Academy of Medicine, on Tuesday and Wednesday, November 17th and 18th. The programme for the Tuesday morning session consists of a "symposium" on What are the Causes Leading to Railway Accidents and what Remedies can be Sug-Eight papers on the subject will be read, and a general discussion will follow. At the afternoon session the president, Dr. F. A. Stillings, of Concord, N. H., will deliver the annual presidential address. In the evening a reception and banquet will be held at Delmonico's. On Wednesday morning, at 9 o'clock, Dr. Howard Lilienthal will hold a clinic at Mount Sinai Hospital, and in the afternoon, at 2:30 o'clock, Dr. Andrew J. McCosh will hold a clinic at the Presbyterian Hospital. The officers of the association are: President, Dr. F. A. Stillings, of

Concord, N. H.; first vice president, Dr. J. M. Wainwright, of Scranton, Pa.; second vice president, Dr. C. A. Pease, of Burlington, Vt.; corresponding secretary, Dr. George Chaffee, of Brooklyn; recording secretary, Dr. C. B. Herrick, of Troy, N. Y.; treasurer, Dr. J. K. Stockwell, of Oswego, N. Y.

Society Meetings for the Coming Week: Monday, November 16th.—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn.,

of the Greater City of New York; Hartford, Conn., Medical Society.

Tuesday, November 17th.—New York Academy of Medicine (Section in Medicine); Buffalo Academy of Medicine (Section in Pathology); Tri-Professional Medical Society of New York; Medical Society of the County of Kings, N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association.

Wennesday, November 18th.—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York; New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club; New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

THURSDAY, November 19th.—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society (annual); Æsculapian Club of Buffalo, N. Y.
FRIDAY, November 20th.—New York Academy of Medicine

DAY, NOVEMBER 2011.—New York Academy of Medicine (Section in Orthopadic Surgery); Clinical Society of the New York Postgraduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

Public Health and Marine Hospital Service Exammations.—A board of commissioned medical officers will be convened to meet at the Bureau of Public Health and Marine Hospital Service, Washington, D. C., on Monday, January 11, 1909, at 10 a. m., for the purp se of examining candidates for admission to the grade of assistant surgeon in the Service. Candidates must be between twenty-two and thirty years of age, graduates of a reputa-ble medical college, and must furnish testimonials from responsible persons as to their professional and moral character. The examination will be physical, oral, writen, and clinical. In addition to the physical examination candidates are required to certify that they believe themselves free from any ailment that would disqualify them for service in any climate. The written examination begins service in any climate. with a short autobiography of the candidate, and consists of questions on the various branches of medicine, surgery, and hygiene. The oral examination includes subjects of preliminary education, history, literature, and the natural sciences. The clinical examination is conducted at a hospital, and, when practicable, candidates are required to per-form surgical operations on a cadaver. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order examination, and will be commissioned in the same order as vacancies occur. Upon appointment the young officers are, as a rule, first assigned to duty at one of the large hospitals, as at Boston, New York, New Orleans, Chicago, or San Francisco. After four years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Promotion to the grade of surgeon is made according to seniority and after due of surgeon as grades occur in that grade. Assistant examination, as vacancies occur in that grade. Assistant surgeons receive \$1,600, passed assistant surgeons \$2,000. and surgeons \$2,500 a year. Officers are entitled to furnished quarters for themselves and their families, or, at stations where quarters cannot be provided, they receive commutation at the rate of \$30, \$40, and \$co a month, according to grade. All grades above that of assistant surgeon receive longevity pay, 10 per cent, in addition to the regu-lar salary for every five years' service up to 40 per cent. after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual For further information, or for invitation to appear before the hoard of examiners, address the Surgeon General, United States Public Health and Marine Hospital Service, Washington, D. C.

Brother Taylor Fulton.

2. Prostatectomy in the Treatment of Prostatic Abscess of Gonorrhœal Origin.-Alexander describes his method of operation thus: The membranous urethra is opened by a median perineal incision. The floor of the membranous urethra is cut from the bulb to the apex of the prostate. prostatic urethra is dilated by passing the index finger through the wound and into the bladder. During this procedure the mucous membrane of the prostatic urethra, and in some instances the prostate itself, is split and an abscess is opened into the urethra. The wall of the prostatic urethra is then examined by touch. The opening of any abscess can be thus detected. The lateral lobes are then enucleated, separately, by breaking through the mucous membrane of the prostatic urethra with the The "line of cleavage" is followed, and finger. the lobe is separated from the bladder wall. middle isthmus of the prostate is broken at its junction with the lateral lobe. The lateral lobe is then free and is delivered through the perineal wound by means of a small lithotomy forceps. After the lateral lobes have been removed, the vesical orifice can be felt as a distinct ring which fits the end of the examining index finger. The hæmorrhage is never very severe. To control this he has adopted the following device: The finger is introduced into the perineal wound and the end of it hooked over the edge of the lower lip of the vesical orifice. flat forceps with a lock in the handle is then passed underneath the finger and the lower lip of the vesical orifice seized and the forceps locked; the finger is then withdrawn and gentle traction is made upon the forceps. This draws the vesical orifice toward the perinæum and compresses the prostatic plexus and causes almost complete cessation of the hæmorrhage. The bladder is then emptied of any clots it may contain and irrigated. The bladder is drained by a metal perineal tube. eight inches long and having upon the shaft a round diaphragm which, by means of a spring attachment, can be slid along the shaft of the tube, and will remain fixed where it is placed. The tube is put in place without the diaphragm, and the wound is packed with strips of folded iodoform gauze by means of long forceps. The hæmorrhage is thus efficiently controlled. The forceps is then removed. Long strips of folded gauze are then wrapped loosely about the tube as it emerges from the wound, so as to form a cushion; this should be thick enough to bring the surface of the cushion

level with the tuberosities of the ischium. The diaphragm is then put upon the tube and pushed firmly down upon this perineal cushion of gauze. A piece of rubber tubing four inches long is then put upon the end of the tube. The tube is held firmly in place and the dressings are applied and held in place by means of a three tail perineal bandage. The outer tails of this bandage cross one another in the perinæum, and the middle tail, which is split for the passage of the tube, is brought firmly over these and fastened in the middle line. The patient is put to bed and simple syphon attachment made to the tube. With the dressing properly in place the patient may turn upon his side. is practically no leakage along the tube. The dressing remains dry, and the tube causes little discomfort. The perineal tube is removed on the day following the operation. The packing is removed at the same time or on the day following, and the wound is then treated as a perineal section.

13. Ear Symptoms of Cardiovascular Disease. With Special Reference to Low Pressure Cases,

By Louis Faugeres Bishop.

4. Endocarditis.—Rosenow says that the blood culture in endocarditis is the best means of making an early diagnosis. It should always be made for the identification and study of the infecting organism as well as for prognostic reasons. accidents, the greater the virulence the more grave the prognosis. The therapeutic injection of dead bacteria in endocarditis has very little influence on the course of the disease until late in the course, when there is a temporary improvement following the injections. A very close relation exists between the biological character of these organisms and their ability to produce endocarditis in the class of cases he observed. The organisms isolated, while of practically no virulence to animals and susceptible to phagocytosis on cultivation, appear to immunize themselves against the antibodies produced by the host, and thus to overcome the resistance of the latter.

5. Anæsthesia Commission Report.-The anæsthesia commission submits three recommendations regarding general anæsthics. I. That for the general practitioner, and for all anæsthetists not specially skilled, ether must be the anæsthetic of choice-ether administered by the open or the drop method. 2. That the use of chloroform, particularly for the operations of minor surgery, be discouraged, unless it is given by an expert. 3. That the training of skilled anæsthetists be encouraged; and that undergraduate students be more generally instructed in the use of anæsthetics. The commission believes that the further use of nitrous oxide combined with air or oxygen, in major surgical operations, is promising.

6, 7. Anæsthesia.—Cunningham and Andersson speak of the methods of administering ether, mentioning the closed, the open or drop method, and the semiopen method, the mechanical administration, rectal etherization, the nitrous oxide-ether, and the nitrous oxide-oxygen-ether combination. They state that the drop method is a very popular one. It is practically safe, while its simplicity makes it the method of choice for the inexperienced. Its shortcomings of perfection are sufficiently important to demand consideration. It produces great refrigeration. Whatever heat is taken from the inspired air by the vaporization of the ether is in turn taken from the lungs, as the exhalation is always at practically body temperature, regardless of the temperature of the inhalation. If refrigeration is a factor in the production of postanæsthetic pulmonary complications, the open or drop method, which is the most efficient of all methods in extracting heat from the patient, would seem to invite the occurrence of postanæsthetic pulmonary involvement. If refrigeration adds to shock, the open or drop method would, regarding the production of shock, head the list of all the methods of administering ether. It produces incomplete diffusion of ether vapor and air because of the close proximity of the application of the liquid ether to the face. Unduly large amounts of ether are required because of the waste of ether from its vaporization by the exhalation. Longer time is necessary to induce anæsthesia. Modern anæsthesia has already reached the stage where refinements of methods are necessary, when skilled anæsthetists are available. That a method possesses no serious obstacles is not enough. Modern surgeons and anæsthetists demand a method of administering ether which overcomes certain minor and too often neglected objections, which are of more or less importance regarding the safety and pleasantness of ether anæsthesia. It may be ventured that hereafter general anæsthesia will not be considered as a whole, but its various stages dealt with according to their obviously different requirements, and that this is to be accomplished by sequences of various anæsthetics administered with an apparatus which is both accurate and practical, and by men whose entire time is given to this branch of the profession.—Haggard reviews the advantages and disadvantages of nitrous oxide. The advantages are: Quickness of action, absence of uncomfortable sensations to the patient, almost immediate recovery, absence of lung complications, absence of danger to the kidneys, absence of postanæsthetic vomiting. Improbability of subsequent fatty degeneration of the kidneys, liver, and heart. It is to be preferred especially when there is a disease of those three great organs, and for the patients who have previously had unpleasant experiences with the other anæsthetics-such experiences as aggravated postoperative vomiting. The disadvantages are: It is not suitable for fat, plethoric, and alcoholic patients. Its zone of anæsthesia is within somewhat narrow limits. Slight lividity and occasional talking occur. We cannot always secure the requisite skill for its successful administration, nor the required quantity of gas, and the proper apparatus. The cost is not inconsiderable. From one to two cylinders of one hundred gallons each are needed for an hour's administration. Contraindications for its use are: It should not be employed for patients with dilated hearts or for those with extremely bad hearts, whether with valvular or myocardial disease. It should not be used in case of narrow or abnormal air passages, of enlarged lymph nodes, goitres, or enlarged tonsils and adenoids.

11. Blood Changes Incident to Surgical Anæsthesia.—Hamburger and Ewing have made such observations. They state that in nitrous oxide anæsthesia the hæmoglobin is not permanently reduced nor is anæmia produced; hæmolysis is not increased; and the changes in the readings of the hæmoglobin and erythrocytes are transient and of no surgical significance, and are most likely to be explained on the basis of capillary stasis. The production of reduced hæmoglobin is not a result of the anæsthetic itself, but is due to the accompanying asphyxia. The changes in coagulation time are not constant, but in general there is an increase in the time required for clotting most marked about the third day. In an analysis of the blood changes incident to ether anæsthesia in a series of experimental observations they find that the hæmoglobin is slightly reduced and therefore a slight anæmia is produced; hæmolysis is not materially increased; the changes in hæmoglobin and erythrocytes are to be explained on the basis of blood inspissation. It causes a marked decrease in the coagulation time, most marked from the seventh to tenth days. In an analysis of the blood changes incident to chloroform anæsthesia in a series of experimental animals, they find that the hæmoglobin is reduced, and therefore an anæmia is produced; hæmolysis is increased; it causes a slight decrease in the coaguiation time, most marked in the seventh to tenth days. In a comparison of the three anæsthetics from the standpoint of the blood changes they conclude that nitrous oxide causes no permanent effects of any significance; that ether causes more harmful changes (slight anæmia and marked decrease in coagulation time); that chloroform causes the most harmful results (hæmolysis and production of distinct anæmia).

 6. Important Flat Foot Facts; for Assimilation and Dissemination,
 By Edward A. Tracy.

1. Suggestions for Reform in the Legal Relations Concerning the Insane.-Hamilton suggests certain measures and makes the following recommendation: There should be obligatory information of the commissioner in lunacy in regard to the existence of all cases of insanity. Though the commissioner in lunacy may have power to license private institutions, he should also be empowered to formulate additional requirements which would put some of them on a much higher standard than they occupy at present. Commitments are chiefly to be looked upon as reinforcements by the judge of the persuasions exerted by the friends, physician, and family of the patient, and should be resorted to only when the latter cannot be persuaded to go to the asylum. Everything should be done to make the appeals of committed patients available. There should be severe punishment for the suppression of letters, or interference in any way with the alleged lunatic's rights. There should be material reform in the attitude of the law regarding capacity and criminal responsibility, insane acts in them-selves, in any relation they may have, receiving more weight than heretofore. There should be a departure from conventions in old and arbitrary definitions. Special insane acts should be studied with reference to the crime itself in a way they have not been up to this time. The attitude of the courts should be much more charitable to the medical witness than it is to-day, the intelligent medical man being put in possession of all the facts in the case and not being obliged to answer restricted questions which place him in a false position, and which are deficient in the presentation of the facts. In all matters involving the determination of capacity or responsibility the medical man should be required to prepare a brief which should form the basis of his cross examination, and this, if necessary, must be supported by extraneous evidence which has received the sanction of the court as to heredity, previous history, and facts communicated by others.

2. Tumors of the Uterus.—Reese says that dysmenorrhora should be considered a symptom when appearing in any period of a patient's life, justifying a thorough examination of the pelvic organs to ascertain the cause of the pain and its removal if possible. A clear diagnosis and some positive indication for removal of uterine fibroid should be ascertained before surgical interference is resorted to. Mixed tumors of the uterus should always be removed as soon as diagnosticated. Simple fibroid tumors should never be attacked surgically, unless in exceptional cases, because they are amenable to constitutional and local treatment.

3. Bituminous Coal Smoke.—Wainwright observes that there are four sets of particles formed in smoke: (1) Carbon particles which escape unconsumed from the burning hydrocarbons giving off the soot; (2) tar vapors; (3) steam; (4) small particles of dust mechanically carried up the chimney by the draft. The proportion in which the four occur in the smoke is entirely dependent upon the condition of the surface of the fire. When the fuel is first put on, tar vapor and steam only escape from the fire below, with particles of complete and incomplete combustion, among which are carbon thonoxide. As the heat works upwards through the

recently added fuel, the products of distillation from the coal catch fire and are partially burned, the result being that the deposited carbon or soot also forms a portion of the smoke, while as the fire burns clearer and clearer and the upper portion becomes incandescent, practically nothing but the products of complete combustion find their way up the chimney. The gases issuing from a chimney consist, firstly, of invisible particles made up for the most part of gases which exist in the atmosphere in such minute quantities as to be capable of doing but little harm. This is true only of gases from ordinary fires and does not refer to the fumes from the chimneys of chemical works, which are capable of doing great harm. Besides these invisible gases, as has been shown, there is the visible portion, consisting for the most part of minute particles of carbon, which are not entirely pure, but contain a certain amount of sticky, tarry matter. Without doubt, the existence of a smoky atmosphere has an influence in increasing mortality. One effect of a smoky atmosphere, even worse than that of breathing the vitiated air, is to be found in the direct effect in causing people to keep their windows shut in towns, and so breathe the even more vitiated atmosphere within. It has for some time been recognized that one of the conditions most favorable to consumption is to be found in defective ventilation. It has been asserted that in suppressing smoke we deprive ourselves of a powerful disinfectant, which, when in the atmosphere that we breathe in crowded cities, tends to guard us against contracting infectious diseases, especially of the nose, throat, eyes, and lungs. This theory is, of course, discredited, for, as a matter of fact, such infectious diseases are more prevalent in large manufacturing centres than elsewhere, and statistics show this to be in a large measure due to a coal smoke ladened atmosphere. A smoky atmosphere, by its exclusion of light, its content of acid and irritating particles suspended in it, is harmful to the tissues of the nose, throat, eyes, and especially the lungs and air passages, whether in a healthy or other condition; aggravates the discomfort of those suffering from all forms of heart disease; increases the distress of those who have nervous complaints; lowers the tone of general health; is a peril to the aged; diminishes buoyancy of spirit, as well as reducing still further an already lowered resistance to disease. What relative part with pathogenic germs smoke plays in causing this class of diseases it is hard to calculate, but it is safe to say that, working together, the danger to health and life is largely increased.

2. Cats as Plague Preventers.—Buchanan states that the duration of plague in India depends on the time it will take before it is generally recognized that the cat is the best plague preventer. The question of plague or no plague is a question of Nature's balance between cats and rats. We may assist by using traps and poison, but can never hope

to compete with the cat.

5. Tropical Liver Abscess. - Charles maintains that there is a tropical liver, with its special ætiology, as a definite disease, distinctive from the congestive liver trouble of temperate climes, and that, as the causes for it become continuous, the effects on the viscus become more permanent, and these causes are most generally due to high temperature and chill, dietetic errors—qualitative and quantitative-alcohol, the abuse of exercise, and its opposite, the inactive life, malaria, dysentery, and diarrhœa. In short, those most likely to lead to degenerative changes, and those most dangerous to a degenerated organ. The capacity of the liver to deal with toxic products ingested depends on its integrity, the amount of deleterious matter absorbed and its quality. Recent researches point to the view that the amœba is not causative of acute dysentery, and is only found, as a rule, in association with other organisms. Its presence is neither concomitant with a definite train of symptoms, nor does it produce a specific type of stool. Its presence is secondary to other microorganisms. Wenyon's observations go to show that there is an amœba which is to be found in the human intestine, both in health and in disease, and which reproduces asexually in the intestine and sexually in cysts, which contain two, four, or eight nuclei, according to the stage of development. These cysts escape to the exterior and transmit the infection to other hosts. amœba is not peculiar to man. Rogers's conclusions regarding tropical liver abscess are as follows: 1. Further experience with ipecachuana in the presuppurative stage of amæbic hepatitis fully confirms his contention that tropical liver abscess can thus be easily prevented. 2. Four fifths of amœbic liver abscesses are free from bacteria and cocci when first opened, or post mortem if previously unopened. 3. In cases of tropical liver abscess proving fatal after the open operation, infection with staphylococci is almost invariably found. The great majority of patients examined at the time of being dressed subsequently to the drainage show a similar infection, which it is almost impossible to prevent in damp, hot climates. 4. Post mortem evidence shows that half of the patients, being fifty per cent, of the total operation cases, dying subsequently to the abscess being opened, conditions are found which almost preclude hope of recovery. In the remaining half of the patients, single or practically single abscesses are found, which afford good hope of recovery under approved methods of treatment. 5. By means of the flexible sheathed trocar liver abscesses may be drained and repeatedly irrigated with quinine solution without the admission of air, with probably better results than the present Calcutta mortality of about sixty per cent. 6. The ipecachuana treatment should always be used after operations for liver abscess, to cure any latent amœbic dysentery and prevent further abscess formation.

12. Occupation Dermatitis.—Gardiner's paper is based on a series of 187 cases of occupation der-The affection occurs more commonly in the later than in the earlier years of life, and is most prevalent during the summer. Among the male patients laborers, miners, painters, joiners, and rubber workers headed the list; among females, housewives, laundresses, and rubber workers. The most frequent causes seemed to be soap and washing materials, moisture and mud, varnishes and paints, alkalies and acids, and naphtha. The parts most commonly affected were the hands alone. In eleven cases the dermatitis was universal. Most of the patients were in good general health. Certain conditions of the skin were predisposing factors. Marked seborrhæa was noted in forty-two cases, and hyperidrosis in twenty-three. Thick sebum is a suitable nidus for germ growth, and renders the extension of an existing dermatitis more probable. Treatment consists in removal of the irritation as quickly as possible, and the application of soothing remedies. Means must then be employed to harden up the skin. Patients often refuse to wait until all the ervthema has subsided before returning to work, and so relapses are very common. The eruption is often made worse by the use of patent remedies. Soaps are the actual provocatives in many cases, and in others aggravate an existing der-

16. Atrophic Rhinitis .- Adam states that the presence of sinusitis should be presumed in every case of atrophic rhinitis, until it is definitely ex-He regards atrophic rhinitis as the end stage of hyperplastic purulent rhinitis for the following reasons: I. Sinusitis, which is so often present, is a hyperplastic process. 2. Sections of hyperplastic cases show changes characteristic of atrophy. 3. Turbinal tissue from cases of chronic sinusitis shows the early changes of atrophy. 4. Inferior atrophy often occurs with middle hyper-Hypertrophy never goes on to atrophy, hyperplasia does. Consanguinity appears in about half the cases. Ozæna is not an essential feature of the disease. Abel's bacillus is the cause of what is erroneously regarded as the specific fœtor, but is not the cause of the disease. The author insists on the importance of treating purulent rhinitis in children, especially when following eruptive fevers. Treatment of sinusitis often results in cure of discharge and fector. Once sinusitis is eliminated, injection of paraffin, solid by preference, often practically cures; it should be preceded by massage. But solid paraffin is often not retained; liquid paraffin is apt to cause thrombosis.

Notes on 679 Operations Performed under Spinal Amesthesia (Cocaine or Stovaine) by Tuffier's Method,

By Dr. SABADINI.

6. Spinal Anæsthesia.—Sabadini's paper, which is based on 679 operations performed under spinal anæsthesia with cocaine or stovaine, goes to show that the method is entirely free from danger, and that the objections which have been urged against it are without foundation. He has never imposed spinal cocainization on his patients, always giving a general anæsthetic when desired. The cases comprised operations of every degree of severity; resection of ribs, hydatid cysts of the liver and peritonæum, strangulated hernia, abscess of the liver, wounds of the abdomen and viscera, and a large proportion of operations on the genital organs, both male and female. The patients' ages varied from fifteen to ninety-three years, so that age in itself is not to be regarded as a contraindication. The operations were always low down-i. e., below the level of the umbilicus, anæsthesia extending upwards as a rule to within two fingers' breadth below the mammæ. To insure diffusion of the cocaine the patient is kept in Trendelenburg's position for ten minutes. The failures to obtain satisfactory anæsthesia amounted to about eleven per cent. Most resistance is shown by alcoholic and nervous subjects. Between the fifth and the fifteenth minute after injection the immediate effects manifest themselves; they are pallor, sweating, nausea, vomiting, and very occasionally marked apprehension. In a very few cases epileptoid tremor of the lower limbs and fatal syncope occur. The writer has never seen an instance of the latter grave accident. Pathological conditions which absolutely prohibit the use of cocaine are advanced cachexia, bilateral nephritis with scanty urinary secretion, myocarditis, pericarditis with effusion, and noncompensated cardiac affections. The only two untoward consequences at a later period are headache and rhachialgia. Patients subject to migraine seem more prone to postoperative headache; it can often be obviated by withdrawing fifteen to twenty grammes of cerebrospinal fluid before injecting the cocaine. Arthritic and alcoholic subjects, especially if suffering from arteriosclerosis, are especially liable to headache after spinal anæsthesia. Rhachialgia is alleged by some observers to be a sign of meningeal irritation, but although a few patients complained of pain in the spine it never amounted to positive inconvenience. The author has never met with a single instance of medullary mischief. His

conclusions regarding cocaine anæsthesia are as follows: 1. Spinal cocainization is absolutely free from danger. 2. Spinal cocainization, by Tuffier's method, may be employed from ten to fifteen years of age up to extreme old age for all operations on parts below a line running horizontally across two fingers' breadth below the breasts, or we may take the eighth rib as a limit. 3. The drawbacks alleged against the method can be minimized by attention to the points referred to to such an extent as to render them quite negligible in view of the advantagesviz., absolute safety, suppression of operative shock. etc. 4. It is an excellent mode of inducing anæsthesia which has been unjustifiably decried, and deserves to be practised under suitable conditions. The author has employed stovaine in 108 cases in patients between eighteen and seventy-one years of age in doses from five to ten centigrammes. On the whole, stovaine anæsthesia seemed to be preferable to cocaine, and the writer concludes: 1. That spinal stovainization is an excellent mode of inducing anæsthesia which may be employed without danger from fifteen years to an advanced age. 2. A dose of from five to ten centigrammes affords good anæsthesia which may last one and a half hours. 3. The constitutional disturbances are slight and never interfere with the performance of the surgeon's duties, and they seem to be less frequent with stoyaine than with cocaine. The only serious drawback is the comparative frequency of urinary retention (fortyfour out of 146 cases), lasting from one to several

Hebotomy or Symphyseotomy? Study of the Comparative Value of These Two Operations,

By CYRILLE JEANNIN.

2. The Action of Stained Bacteria,
By F. DAELS and R. DEVLOO.

Hebotomy or Symphyseotomy?—Jeannin concludes that pubiotomy is superior to symphyseotomy for the following reasons: I, It substitutes an osseous for an articular wound; 2, the technique is easy and the operation is performed in a less dangerous zone; 3, immediate accidents are less frequent and remote accidents are much more rare; 4, the mortality, both feetal and maternal, is much less; 5, in case of repeated intervention the operation can be performed on the opposite side.

2. Action of Stained Bacteria. - Daels and Devloo present some interesting results of their experiments made by centrifuging cultures of various bacteria, staining them with methyline blue or fuchsin and injecting them, usually into the vitreous

of a rabbit.

Death of Ascitics after Paracentesis.-Perrin, after a study of the accidents which may follow paracentesis for ascites, which he classes in five principal categories, viz., serous anæmia, icterus gravis, hæmorrhages of the abdominal wall, hæmorrhages of the digestive canal, and cardiac dilatation

a vacuo, comes to the following conclusions: I, In every case of cirrhosis the physician should rigidly insist on the proper diet and treatment and not waste time with half measures. 2, In every case of puncture for ascites the condition of the heart should be investigated, and when indicated a preventive cardiac tonic treatment instituted. the elements of prognosis should be weighed in each particular case. 3. A small trocar should be used, the dorsal decubitus should be maintained, and a very firm bandage should be placed about the body immediately and kept in place for a week or longer if the patient gets up. The place of election should be at the junction of the middle and outer thirds of the umbilicoiliac line. 4, After the operation the patient should not be left, but should be closely watched in order to be able to institute in time any medication which may be necessitated by the occurrence of any of the before mentioned accidents. 5, It is good professional prudence to mention to a member of the patient's family that the operation is not always successful and to advise how the case permits the possibility of this or that complication.

3. Anæsthesia with Ethyl Chloride.-Vennin presents an apparatus which has the advantages of securing an atmosphere very rich in the active vapor and at the same time permits the minimum dose of the drug to be used.

11. Concerning Idiosynerasics, By EDUARD HESS

12. Modern Theories Concerning the Action of Inorganic Medicaments, By T. A. MAASS.
The Water Jet Air Pump in the Service of Medicine, especially in Suction Treatment, By ARTHUR STRAUSS.

2. Treatment of Experimentally Produced Nagana. Friedberger finds that atoxyl, which

does not possess the power of killing tryanosomata in the test tube, obtains such a power through the addition of thioglycolic acid, and that the tympanicide power of such a mixture slowly increases. The freshly prepared mixture is not poisonous to the mouse, but after standing it acquires poisonous properties. After a mouse has been infected with nagana, even after it has carried tryanosomata in its blood for several days, the parasites can be removed by means of this mixture, yet, because of the greatly poisonous character of older mixtures, he recommends that mixtures more than two or three days old should not be employed. From his results thus experimentally obtained he suggests that this mixture might be tried in the sleeping sickness and perhaps in syphilis.

6. Tremor.—Panichi has studied the single contractions of the heart by means of Mosso's ergograph, and shows by illustrations the distinctive tremor met with in multiple sclerosis. His conclusions are that the peculiar type of the ergographic curve does not show itself in the individual contractions during fatigue, that the individual character shows itself on the contrary constantly during pathological processes, and that the ergographic curve brings into evidence the segmentary tremor in the single contractions in patients who are suffering

from multiple sclerosis.

7. Diseases of the Optic Nerve in the Early Stages of Multiple Sclerosis.-Schley declares that affections of the optic nerve are not only frequent in multiple sclerosis, but that they often precede by a longer or shorter time the appearance of other symptoms of the disease. The clinical symptoms are extremely varied, as are likewise the ophthalmoscopic changes. When such troubles appear as the first symptoms of multiple sclerosis the diagnosis is extremely difficult; among the conditions to be excluded are syphilitic neuritis, toxic neuritis from a variety of poisons, tumor of the brain, and, if the nerve looks normal, hysteria.

8. Ætiology of Diabetes Mellitus.—Bleibtreu reports two cases of diabetes mellitus in which pathological conditions in and about the pancreas were

demonstrated.

11. Idiosyncrasies.—Hess considers idiosyncrasies as racial and individual. The former, he thinks, can be ascribed to climate, geographical, and other appreciable influences; the latter he is unable to explain, but leaves it as a problem to the future.

15. The Practical Importance of the Opsonic Index in
Tuberculosis,
By TURBAN and BAEK. Tuberculosis,

16. Cystoserum Prophylaxis and Pneumonia Infection,

2. Nervousness and Nutrition in Children .-Siegert finds the nervousness of children of the well to do to be dependent more or less on food containing a disproportionate amount of proteid matter and too few vegetables.

4. Epithelisation of Granulating Surfaces by Scarlet Red Ointment.-Kracka reports excellent results by the use of scarlet red ointment in combination with epithelial grafts on granulating surfaces. The ointment is thus prepared: Scarlet red is dissolved in chloroform and triturated until all the chloroform is evaporated, and is then mixed with sufficient yellow petrolatum to make an eight per cent. ointment.

5. The Fear of Tonsil Operations.-Hopmann declares that all tonsils which cause disturbance should be radically removed under general anæsthesia. Such an operation carefully performed is not more offensive and dangerous than the usual procedures for extirpation of the tonsil which, as a rule, result in, or have in view, only a partial re-

moval of the tonsils.

7. Meningococci Sepsis. - Liebermeister reports a case of this rare affection and states that only one other case is recorded in literature. symptoms are given as a hectic, irregular fever, pains in the joints, tension of the masculature, slight stupor, euphoria, emaciation, sometimes an eruption like roseola, hypostases in the lungs, all symptoms such as we are accustomed to see as accompanying symptoms of true epidemic meningitis.

11. Dangers in the Use of the So Called Acetic Essence.—Bleibtreu reports three cases of poisoning with Essigessenz, an eighty per cent. solution of acetic acid, one of which proved fatal. The patient who died had drunken two teaspoonfuls of the concentrated essence. Autopsy showed a severe burning of the œsophagus, trachea, and mucous

membrane of the stomach.

13. Histological Diagnosis of Tumors as a Basis for Radical Surgical Intervention .- Rovsing reports two cases in which amputation was recommended because of the histological diagnosis of the presence of tumors and declined by the patients who later made good recoveries, and proved that amputation was unnecessary. The conclusion drawn is that absolute reliance should not be placed on the histological diagnosis in doubtful cases.

5. Diseases of the Iris and Ciliary Body, By MATTHIAS LANGKION FOSTER reports a case in which a woman of middle age awoke one morning with pain in her left cheek and eye, some swelling of the side of her face, and some congestion of the eyeball. Two days later she was unable to open her mouth, and the physician who was called in could not force her jaws apart. This physician incised her gums above her badly decayed teeth, but found no pus. A day or two later the swelling of the side of the face and the protrusion of the eyeball had become great and were not lessened by the flow of pus that now appeared from the incision in the gum. About three weeks later incisions were made deep into the orbit in four places, but no pus found, and the accessory sinuses explored without result. A day or two after these operations pus appeared from the incision on the nasal and lower side of the eyeball, but this did not affect the protrusion of the eye. Later an abscess near the outer canthus was opened and a probe introduced led along the margin of the orbit to the nasal bone. Two months and a half after the onset of the trouble an exploratory operation in the orbit revealed a localized periostitis. Some five months later another operation revealed an opening through the sphenomaxillary fissure that led into an abscess cavity in the zygomatic fossa. This was curetted and cleansed, and the patient made a good recovery. Foster points out the difficulties that attend the diagnosis of this very rare condition, calls attention to the extremely misleading results of the earlier interventions in the orbit, all of which seemed to indicate that the focus of inflammation was to the nasal side of the eyeball, while in reality it was to the temporal side, and ascribes its ætiology to the lodgment of pathogenic organisms in the fossa, brought there from a neighboring carious tooth by the blood or lymph channels.

Immunization against Tuberculosis.-Dr. A. CALMETTE and Dr. C. GUÉRIN, of Lille, said that in 1906 and 1907 they had published a series of papers which showed that it was possible to produce a marked resistance to artificial tuberculous infection by way of the digestive tract in young as well as in old animals. The resistance was obtained by feeding the animals with fine emulsions of bovine tubercle bacilli, virulent or modified by heating them to 70° C. In cattle a single ingestion of virulent bacilli usually sufficed to produce an infection so slight that, after reacting to tuberculin for one, two, or three months the animals ceased to react and became capable of resisting the large and repeated doses of tubercle bacilli which infected the control animals for more than a year. Animals "vaccinated" by this method continued to harbor virulent living bacilli in their mesenteric lymph nodes, which were capable of infecting guinea pigs for three

months. Later the animals got rid of the bacilli, which could not be found after a period varying from four to six months. If at the latter time the animals were tested by intravenous inoculations with strong doses of virulent bovine bacilli (five milligrammes), simultaneously with control animals of the same age, it was found that the controls always developed an excessively rapid granular tuberculosis, which proved fatal in from four to six weeks; while the "vaccinated" animals maintained every appearance of perfect health for at least eight months. Following this, and all at once, the immunity of these animals disappeared, as shown by the fact that some of them suddenly presented tuberculous lesions in various localities. Those that did not show lesions when killed were found to have mediastinal and bronchial lymph nodes which contained living bacilli that were virulent to guinea pigs, even though there were no other microscopic tuberculous lesions. It was evident, therefore, that the bacilli introduced into the veins of "vaccinated" animals were not absorbed. This fact explained the occurrence of living virulent bacilli in the bronchial and mesenteric lymph nodes of the cattle "vaccinated" by von Behring's method. So long as the animals harbored the bacilli they could not be considered to be really "vaccinated." They merely possessed a special resistance against fresh tuberculous infection, a resistance which was in every respect comparable to that which Koch first observed in tuberculous guinea pigs that had received subcutaneous injections of a second dose of virus. The second inoculation produced a local abscess which soon emptied itself, and the ulceration which followed healed while the first infection continued to produce its effect more slowly. The same resistance could be obtained by intravenously injecting healthy cattle with large doses of tuberculin two or three times at intervals of six or ten days. Animals prepared in this way reacted to the second or third injection as though they were tuberculous. If after the last injection of tuberculin an intravenous injection of five milligrammes of virulent bovine bacilli was administered, and healthy control animals were simultaneously subjected to the same treatment, the controls were attacked with a very rapid granular tuberculosis which proved fatal in from five to six weeks, while animals prepared by previous injections of tuberculin merely presented very slowly progressing tuberculous lesions. The same phenomena were observed in cattle already affected with spontaneous tuberculous lesions, and reacting to tuberculin. The intravenous injection of bacilli was never followed by the appearance of acute granular tuberculosis in those animals. There was no doubt, therefore, that tuberculous animals, and healthy animals prepared by previous large doses of tuberculin, possessed incomparably greater resistance than animals that were new to the intravenous test inoculation. It was evident that cattle vaccinated intravenously with human bacilli, or subcutaneously with bovine or human bacilli, and animals treated by introducing capsules containing cultures of tubercle bacilli under the skin, acquired, by an identical mechanism, a marked resistance to tuberculous infection. Cattle prepared in such a manner preserved the ap-

pearance of perfect health for a variable length of time; they often lost their power of reacting to tuberculin, but they were, nevertheless, carriers of tubercle bacilli, and were capable of contracting a chronic form of tuberculosis. It could not be said, therefore, that this was a true immunity. Similar observations had frequently been made in human beings. It was well known that a local suppurative lesion occurring in a consumptive improved the patient's condition and considerably increased his resistance; conversely, persons in whom pulmonary tuberculosis followed a rapid course had rarely suffered previously from suppuration of lymph nodes, bones, or cutaneous structures, except those in whom ill advised surgical operations might have produced a blood infection. It was recalled that certain clinicians maintained that they had obtained genuine improvement in tuberculous patients by a subcutaneous inoculation of cultures of virulent bovine bacilli or dead bacilli or cultures of human bacilli modified by being passed through the body of a cold blooded animal. The experimental facts above referred to were calculated to a certain extent to justify their assertions. Such a mode of treatment, however, was to be condemned, particularly since we possessed in tuberculin an equally efficient and less dangerous remedy by which the same object could be obtained.

Experiments in Immunization against Tuberculosis.—Dr. Julius Bartel, of Vienna, said that the behavior of tubercle bacilli that had entered the body through natural channels indicated a protective action against the infection on the part of the cells of the organs, and especially of the lymphocytes. In the test tube, it was possible, by the aid of the various organs, especially the organs of a lymphatic nature, to render virulent tubercle bacilli nonvirulent by confining them for some time within the organs at a temperature of 38° C. This was true of human as well as of bovine bacilli. In the course of attempts to produce immunity on this principle, animals had been successfully immunized against an infection which proved fatal to the control animals. Hence the attempt to utilize this action of the component cells of the organs on the tubercle bacilli as the basis of immunization against

action of the component cells of the organs on the tubercle bacilli as the basis of immunization against tuberculosis had proved successful.

A Contribution to the Study of Tuberculous Immunity.—Dr. JULES COURMONT and Dr. A. LESIEUR, of Lyons, said that opinions were divided as

to whether the reinoculation of tuberculosis at another point on the body of an animal that was already tuberculous would give a positive or a negative result. In their work for the purpose of throwing some light upon this subject, in which guinea pigs were used, they employed very virulent bovine bacilli, introducing them by the transcutaneous method of inoculation. If a guinea pig which had been tuberculous for from thirteen to twenty days was inoculated under the skin, the glandular reaction was feebler than it was in the control animals; but such results were not conclusive. When two transcutaneous inoculations were made at intervals of two weeks the reinoculation was negative; no local lesion was produced; the lymph nodes did not become tuberculous; they were scarcely hypertro-

phied; and they were never caseous. No general

effect was produced in the spleen or elsewhere. On the other hand, if the animals were allowed to live, the first inoculation ran its normal course, was accompanied by general lesions, and ultimately killed the animal. This proved that a lesion in the course of evolution prevented the development of a second inoculation. The experiments suggested the question as to the immunity to reinfection of a human being in the course of the evolution of a tuberculous infection.

Immunity Produced by the Inoculation of Increasing Numbers of Bacteria, Beginning with One Living Organism; its Therapeutic Application.—Dr. GERALD B. WEBB and Dr. W. W. WIL-LIAMS, of Colorado Springs, and Professor M. A. BARBER, of the University of Kansas, said that the attempts to produce lasting immunity against tuberculosis by the inoculation of dead tubercle bacilli or their products had not proved satisfactory, On the other hand, the inoculation of attenuated organisms had given some evidence of the production of a true immunity. The fact that probably sixty per cent. of all autopsies on human beings showed healed tuberculous lesions suggested the existence of a relative degree of acquired immunity to tuberculosis. They described the technique, perfected by Professor Barber, by which one organism could be selected from a culture and injected into an animal. They began their experiments with this form of vaccine by using anthrax bacilli in mice. The first dose given consisted of one thread of three organisms, and the dose was gradually increased up to 500 threads. In that way they produced immunity in mice to anthrax bacilli. They then employed the same technique for the production of immunity to tubercle bacilli in guinea pigs. They gave the animals one tubercle bacillus and gradually increased the number to over 10,000 bacilli at a dose, without producing tuberculosis in the animals. They then employed the method for the treatment of rabbits previously rendered tuberculous by feeding them with tubercle bacilli, with good results. Similar therapeutic tests had been made on human patients with results that were encouraging, but about which it was still too early to make very positive statements.

Tuberculins and the Measure of their Activity. -Dr. A. CALMETTE, of Lille, said that Koch's old tuberculin consisted of a simple glycerinated extract of bouillon cultures sterilized by heat and concentrated on the water bath down to one tenth of its original volume, then filtered through thick paper or a Berkefeld filter. It unfortunately contained a large quantity of albumoses, peptones, and salts of glvcerin, in addition to the secretory products of the tubercle bacilli. These foreign substances produced a temporary rise of temperature in nontuberculous subjects, thus masking the effects due to the tuberculin itself. This defect was overcome by mechanically crushing the dried bacilli and then separating the soluble from the insoluble products by washing with slightly alkaline water, thus producing the tuberculins known as TO and TR. Other tuberculins had been produced by various workers by treating the cultures with varying chemical substances, isolating a long list of products, "tuberculocidin," "tu-berculoplasmin," "tuberculosin," etc. These substances did not seem to possess the same physiological and therapeutic properties as the old tuberculin. Denys and Buden employed a culture filtered through a Chamberland candle, and still other workers produced a simple aqueous extract of bacilli without glycerin.

These various products showed the desire on the part of experimenters to obtain a substance that would have all the advantages of the old tuberculin without its disadvantages. The reader described a tuberculin which he had produced, known as tuberculin CL, which was so pure that it could be introduced into the veins of a healthy animal in large doses without producing an elevation of temperature. If the large doses used, fifty milligrammes, were repeated three times at intervals of from six to ten days, the animal was observed in from five to twelve hours after the third injection to react by a rise of 1.8° to 2.5° of temperature, just as if it were tuber-Following this phenomenon, the animals became highly resistant to artificial tuberculous infection. The intravenous injection of a dose of virulent bovine tubercle bacilli sufficient to produce an acute miliary tuberculosis in control animals in from four to six weeks merely resulted in a chronic, slowly progressing tuberculosis in an animal prepared with a previous injection of the tuberculin. product, tuberculin CL, was obtained by centrifuging entire cultures of the bovine bacillus in vacuo and at a low temperature. The product was then filtered in order to separate the bodies of the microorganisms, precipitated three times with alcohol and ether, redissolved in water, and dialyzed until all the precipitants and salts had been completely eliminated. The colloid substances which remained on the dialyzer were then again precipitated with alcohol and ether. and dried in vacuo. The active substance, therefore. was not modified by being subjected to heat or to chemicals aside from the precipitation with alcohol and ether. The activity of this product could be judged by comparing its action with that of any of the other tuberculins, or by the method of direct inoculation into the brain of a healthy guinea pig. By the latter method 0.8 of a milligramme sufficed to kill a healthy animal—one tenth as much as was required of the old tuberculin. The tuberculin CL was very well borne by patients, and those physicians who had used it therapeutically had obtained excellent results. It did not cure the disease, but it did delay its progress and seemed to give the person infected some additional resistance to its progress. The best results were obtained with a very small amount, 0.001 of a milligramme, as a primary dose, which was gradually increased until 0.3 of a miligramme was finally given. The injections were given at ten to twelve day intervals, so as to avoid a reaction of more than half a degree centigrade. It was considered wise to keep track of the opsonic index during the course of the treatment with this product, and to see that it was at least maintained at the same level after as before the beginning of the treatment. The tuberculin CL possessed an affinity for the lipoids that were almost constantly contained in the serum of tuberculous patients. The tuberculin was indicated for the determination of the affinity of the patient's serum for the secretory products of the tubercle bacilli, as well as for the diagnosis of the

The Therapeutic Value of the Tuberculins .-Dr. SAMUEL BERNHEIM and Dr. P. BARBIER, of Paris, said that the endeavors to discover a specific remedy for tuberculosis might be divided into those that sought to produce an active immunity, which necessitated a defensive reaction on the part of the patient with the production of antibodies, and those that endeavored to produce passive immunity, which did not require a reaction on the part of the patient, since the antibodies were already furnished to him. They believed that the future outlook for the usefulness of serum therapy in a chronic affection like tuberculosis was extremely doubtful. The methods of active immunization, on the other hand, held out more hope of success. They were divisible into, first, the inoculation of cultures of virulent or attenuated organisms, tuberculins; and, second, the inoculation of the soluble products of the organisms, toxines. The authors had made a critical study of seven different tuberculins, and as a result they concluded that there was great necessity for a prudent and methodical employment of the product. The reason for the failure of the old tuberculin was that it was employed in too large doses, so that dangerous reactions were produced. All recent authors were agreed that every appearance of reaction should be avoided. The small doses used at the beginning of the treatment should be very gradually raised, so that the immunization of the organism should progress by "mithrydatism," as Sahli called it. They believed that the opsonic method of Wright allowed one to observe exactly the degree of immunization that the patient had reached and the intensity of it. The method of determining the opsonic index was considered a valuable guide in deciding questions of doses. The chance of success in the treatment of tuberculosis with tuberculins depended upon the state of the resisting power of the patient. The opsonic method was considered to be of great value in the estimation of this power. The tuberculins which contained the intracellular toxines of the bacilli were probably the ones which would possess the most active immunizing proper-

Dr. ROBERT KOCH, of Berlin, said that it was possible to produce immunity in bovine animals by repeated inoculation. Although the animals were thus rendered immune, their lymph nodes contained active tubercle bacilli for a long time, and it was injudicious to slaughter them and use them for food. He was skeptical concerning the results of attempting to produce immunity in human beings by the inoculation of living bacilli, and he warned the profession against raising too much hope concerning the therapeutic value of this method. He had originally said that it was impossible to inject one tubercle bacillus, but after having seen the demonstration of the method of Professor Barbier he had been convinced, and expressed high praise of the ingenuity of the method.

Dr. É. A. TRUDEAU, of Saranac Lake, N. Y., said that to his mind it was a question whether the resulting condition of the system of those animals that had received inoculations of living bacilli was really one of immunity. He agreed that the bacilli lived in the tissues for a long time. There was some hope that a practical method would be found in the

future for producing immunity. Formerly, in his laboratory, "vaccines" were produced by attenuating the organisms after approved methods. The single bacillus inoculation was very ingenious and very interesting. In his experience he had never succeeded in obtaining results from "vaccination" after infection.

Dr. M. J. Rosenau, of Washington, said that anaphylaxis or supersusceptibility had a most important bearing upon susceptibility and immunity. The tuberculin reaction was an example of anaphylaxis. Upon applying the tuberculin test, a reaction at once was evidence that the patient was in the best condition to resist the infection, and that a local focus of the disease would probably not spread. It was an indication of power to produce a cure within the body of the individual showing it.

(To be continued.)

Petters to the Editors.

STATE EXAMINATIONS IN CHEMISTRY.

To the Editor:

Springfield, Ill., October 31, 1908.

I have no desire to prolong the discussion of the examination questions of the Illinois State Board of Health with Dr. W. G. Tucker, professor of chemistry in the Albany Medical College. The keynote of Dr. Tucker's remarks in the New York Medical Journal of October 17th has been that State examining boards should mould their questions according to the dictum of teachers of chemistry-of which he is one-and it is clear that he regards the board which fails to so frame its questions as hopelessly and irretrievably wrong. It is obvious that a controversy, however extended, between one who is confirmed in the belief that he is one of the elect, to dictate, and a body which this gentleman believes to be acting wisely only when following his counsel, could never reach a satisfactory conclusion.

Furthermore, I am not particularly desirous of discussing questions in chemistry with a gentleman who first maintains that a certain oxide of potassium called for in the examination questions of the Illinois State Board of Health has no existence, and who, when confronted with evidence that it certainly does exist, naively remarks that it is not mentioned in a dictionary which he possesses—apparently unconscious of the ludicrousness of the spectacle of a man who has taught chemistry for thirty years attempting to negate a chemical body simply because he is unable to find it in a dictionary he happens to own.

Aside from satisfying Dr. Tucker—which seems hopeless—there are one or two points of general interest in his letter which appeared in the Journal for October 17th. In this letter Dr. Tucker admits that questions similar to those with which he finds fault in the Illinois questions—and which he says are not a fair test of the qualifications of the medical candidate—are to be found in the examinations of the State of New York. He explains, however, that the New York examination overcomes this difficulty by asking more questions than the candidate has to answer. Just how the applicant

manifests his chemical education by the questions he does not answer is beyond the reach of ordinary comprehension. It will be noted that Dr. Tucker has carefully refrained from any criticism of these questions.

In straining at the proverbial gnat—in a studious effort to pick flaws in my communication—Dr. Tucker has quibbled over the technical meaning of the terms "formula" and "equation"—in which he may be technically correct—and has overstepped the bounds of courtesy in splitting hairs on English words. It was seemingly impossible for Dr. Tucker to fathom my meaning unless I meant "synonym" when I said "analogue." If he will lay aside his Watts and take up his Century for a moment, Dr. Tucker will find that I meant exactly what I said when I employed "analogue" to indicate "a word

corresponding with another."

Overlooking the fact that reformation, like charity, should begin at home, Dr. Tucker has journeyed across the Alleghenies to criticise alleged faults which might be found far nearer to his own doorpost. He has branded examining boards as "independent, impatient with interference, and arbitrary' because such boards have not at once abandoned all established methods to fall in line with the views of himself and his fellows. He has charged these boards with dealing with chemical fictions because they spoke of things which had not come within the range of his personal information or the covers of his dictionary. He declares that the members of his own limited pursuit should act as counsel and censors for examining bodies, failing to realize that a State may desire to determine through its own officers what sort of product the teachers turn out. He excuses his unfounded assertions upon the defects of a dictionary, and answers back with wearying quibbles over the niceties of verbal differentia-He assails me with the stinging indictment that, if I am not wrong, I am certainly ungram-

Reforms in medical examination have progressed rapidly during the past few years and are still progressing. But if examining boards should attempt to conform with the views of all those who designate themselves competent to dictate in such matters, the conditions would change from those which are reasonably satisfactory, if in some ways faulty, to a state which would be hopelessly chaotic.

Still, the Illinois State Board of Health will always welcome, as it has in the past, any suggestions or criticisms concerning the administration of the medical practice laws of Illinois, coming from medical men of this State. Many such suggestions have been tendered to the board, and some of those which have been adopted have contributed not a little to the efficiency of the service. The requirement of a properly authenticated photograph of the applicant, to insure identification—a requirement in which Illinois was the pioneer—was adopted at the suggestion of an Illinois physician who attended one of our examinations, while the "Illinois method" of properly crediting the candidate for his years of practice had its origin in a similar source. The character of the Illinois questions has been criticised more than once, but there has never been an unfavorable comment from Illinois physicians or

teachers as to the questions in chemistry—and Illinois is credited by those of reasonable judgment with many teachers of unusual ability and attainment. The first strictures and complaints have come from the far off Hudson.

Dr. Tucker has admitted that the Illinois questions, to which he takes exception, could doubtless be answered by "recent graduates and men fresh from the study of general chemistry"; but he reminds me that many men who appear for examination have been practising medicine for years, and it is upon these that he feels the questions work a hardship. He ignores the fact, of which he is possibly not aware, that Illinois makes due allowance for the years of practice of applicants for licensure, by a method which has received the hearty approval and commendation of the New York Medical Journal and other medical periodicals throughout the United States. Here I might ask Dr. Tucker what special provisions of credit the New York State Board of Medical Examiners makes for the older practitioners, for whose welfare he is so solicitous. Yet Dr. Tucker advises us that State boards which do not take the older practitioner into consideration need to be reformed, and he promises that reformation as an absolute certainty!

Recalling Dr. Tucker from his career in the field of foreign missions to other conditions in his own State which merit the attention of those of true missionary and reformatory spirit, it may be remarked that in the Empire State an osteopath sits on the State Board of Medical Examiners and grades the papers on physiology of the graduates of all of the New York medical colleges-including the Albany Medical College. No doubt this gentleman is qualified to perform the duties assigned to him—but an osteopath rating physicians' papers! Shades of Æsculapius, of Samuel Hahnemann, too -of the fathers of the New York medical profession-and then some! And this in the Empire State, in which it is not deemed meet or proper that the governor should appoint the State Board of Medical Examiners, and where, with infinite wisdom, the control of the practice of medicine is vest-

ed in the State University!

And if this were not enough, the professor of ophthalmology of the Albany Medical College may, almost any day, be called in consultation by an "optometrist," who, but a year ago, was a vendor of spectacles, but who now proudly displays a license granted to him by the sovereign State of New York,

and which was his for the asking.

The subject of reciprocity might well occupy a part of Dr. Tucker's consideration. He, in common with all members of the faculties of the New York medical colleges, must desire that their graduates, who have qualified before the New York State Board of Medical Examiners, be permitted to practise, without further examination, in any other State in the Union. If this salutary state of affairs could be established, it would become quite unnecessary for the physicians and teachers of New York to look with so much concern upon the examination questions of other States. Yet, through its arbitrary and indefensible position, the New York State Education Department makes it necessary for the New York licentiate to submit to examination in al-

most every State in which he may wish to practise. For some years past, the Regents of the State University have been empowered by law to enter into reciprocal relations with other States, but until recently they have steadfastly refused to avail themselves of this authority. Only within the past two years has New York reciprocated with any State west of the Alleghenies, and the first steps in this direction were taken with the greatest reluctance and unwillingness.

In his thirst for reform, it might be helpful for Dr. Tucker to recall the admonition of the Scripture, and to devote his energies to the beam in the medical eye of the Empire State, rather than to the

mote in the eyes of others.

JAMES A. EGAN.

*** Watts's Dictionary of Chemistry, as all chemists are aware, is not a mere defining dictionary. It is really a cyclopædia of chemistry, and it is quite reasonable to question the existence of any compound which is not mentioned in a recent edition of the work.

Book Rotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Medical Greek. Collection of Papers on Medical Onomatology and a Grammatical Guide to Learn Modern Greek. By Achilles Rose. New York: Peri Hellados Publication Office, 1908. 12mo. pp. 262.

Dr. Rose is well known as an energetic and persevering advocate of the use of the Greek language in the formation of new scientific terms. In that contention he has the support of all scholarly members of the medical profession, but, like most reformers, he carries his propaganda to extremes, seeking to uproot terms which, faulty though they may be, have become too firmly established to be superseded, and deriding some formations which have been regarded as legitimate ever since we have

had a medical onomatology.

It is particularly hopeless, we think, for him to advocate the use of modern Greek pronunciation. If Dr. Herbert Krüger's exposition of that pronunciation, as translated by Rose (pages 247 et seq.), is correct, a language that for beauty and adaptability has commanded the admiration of the world has no sounds corresponding to those of our long a and long o, while η , t, ω , and ω are all pronounced like the English ee; that is, it is prodigal in characters, but miserly in sounds. However, Dr. Rose's efforts are reasonably sure, we hope, to result in some improvement of our present terms.

A Textbook of Operative Surgery, Covering the Surgical Anatomy and Operative Technic Involved in the Operations of General Surgery. Designed for Practitioners and Students By Wigger Store Bushlay, M. D., Phar. M., Junior Surgeon, Touro Hospital, New Orleans; late Surgeon to Manhattan State Hospital, New York, etc. Third Edition, Greatly Enlarged. Containing 854 Illustrations. Philadelphia and London: W. B. Saun ders Company, 1908. Pp. 1206. (Price, \$6.50.)

This last edition of Dr. Bickham's very meritorious work is decidedly augmented in volume, but the book is not yet unduly large. The text is trustworthy and admirably clear, and the illustra-

tions, as before, are most excellent; Miss Fry's vivid drawings still pervade the volume, and Mrs. Farnsworth has contributed a number of exceedingly praiseworthy illustrations. We can only regret that it has been thought necessary to employ such excessively glazed paper. We believe that the cuts would have shown well on paper less trying to the eye. It is highly probable that many more editions of this admirable work will be called for.

A Manual of Midwifery. By Thomas Watts Eden, M. D., C. M. (Edin.), F. R. C. P. (Lond.), F. R. C. S. (Ed.), Obstetric Physician with Charge of Out Patients and Lecturer on Practical Midwifery and Gynæcology, Charing Cross Hospital, etc. With 42 Plates and 236 Illustrations in the Text. Second Edition. Chicago: W. T. Keener & Co., 1908. Pp. xii-555. (Price, \$3.50.)

Though the present edition of Dr. Eden's work bears evidence of careful revision, and though some portions of the text have been amplified, the book is not materially increased in size. It is still a convenient and very valuable condensed textbook of

obstetrics.

Diseases of the Eye. By S. Stephen Mayou, F. R. C. S., Late Hunterian Professor, Assistant Surgeon, and Pathologist, Central London Ophthalmic Hospital, etc. With 119 Original Illustrations and 8 Color Plates. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. xii-388.

Mayou has aimed to give students and practitioners a short, practical manual dealing more fully with external diseases and the commoner affections of the eye than with rare fundus conditions, and making a choice, for the reader, in methods of treatment, operations, and theories of disease. The result is a very readable and instructive manual. The illustrations are, in the main, excellent, particularly the black and white semidiagrammatic sketches of typical fundus changes and extraocular diseases. The reproductions of microscopical sections are on too small a scale to be readily intelligible. The discussion of disorders of motility is more than usually terse and clear, and the chapters on examination routine and on the typical ophthalmic operations are worthy of special mention.

Mikroscopie und Chemie am Krankenbett. Für Studierende und Aerzte bearbeitet. Von Professor Dr. H. LENHARZT, Direktor des Eppendorfer Krankenhauses in Hamburg. Fünfte, wesentlich umgearbeitete Auflage. Mit 85 Textfiguren und 4 Tafeln in Farbendruck. Berlin: Julius Springer, 1997. (Through G. E. Stechert & Co.) Pp. 405. (Price, \$2.25.)

This book appeared for the first time in 1893, and has since then seen four editions. The present edition has been brought up to date. Of very great value are four bacteriological tables in color, which are as natural as such microscopic colonies can be reproduced. When examined with a magnifying glass, the fineness of the illustration and the distinguishing features of the bacilli are even more pronounced. They represent twenty-one different kinds of bacteria, among them a very good illustration showing the *Spirocheta pallida*.

The text of the book is divided into six parts, with an introduction treating of the use of the microscope and an addendum giving in condensed form microscopical examinations of the secretions of the mammæ and of the vagina, of the products of abortions, and of cow's milk. Part i deals with the vegetable and animal microorganisms; part ii

with the examination of the blood; part iii with the sputum; part iv with the secretion of the mouth, stomach, and intestines; part v with the urine; and part vi with fluids obtained by puncture. Good black and white illustrations help the reader to understand the text.

The Principles and Practice of Gynacology. For Students and Practitioners. By E. C. Dudley, A. M., M. D., Ex-President of the American Gynacological Society; Professor of Gynacology, Northwestern University Medical School, etc. Fifth Edition, Revised and Enlarged. With 431 Illustrations and 20 Full Page Plates in Colors and Monochrome. Philadelphia and New York: Lea & Febiger, 1008. Pp. 13-17, 10, 200 Febiger, 1908. Pp. 13-17 to 806.

Dr. Dudley has so condensed certain parts of this standard treatise as to enable him to introduce considerable new matter without greatly increasing the size of the book. There are two entirely new chapters. One of them, an Introduction, is taken from the author's presidential address before the American Gynæcological Society, delivered in 1905. The other is on incontinence of urine in women. He objects to the formation of a bar by the injection of paraffin, intimating that it does not give good results and declaring that it endangers life by giving rise to pulmonary embolism. He describes an ingenious operation by advancement of the distal portion of the urethra, which he attaches in the neighborhood of the clitoris. He says that he has performed it many times with almost uniformly gratifying results.

Dr. Dudley's work is deservedly a favorite with the profession, and this new edition will be welcomed.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Intestinal Autointoxication. By A. Combe, M. D., Professor of Clinical Pædiatry at the University of Lausanne (Switzerland); Chief of Clinic for Children's Diseases; President of the Swiss Pædiatric Society. Together with an Appendix on the Lactic Ferments with Particular References of the Children Professor of the Children Prof ence to their Application in Intestinal Therapeutics. By Albert Fournier, formerly Demonstrator at la Sorbonne, Paris. Only Authorized English Adaptation. By William Gaynor States, M. D., Clinical Assistant, Rectal and Intestinal Diseases, New York Polyclinic, etc. With Eighteen Figures in the Text. Four of which are Colored. New York: Rebman Company, 1908. Pp. xviii-461. (Price, \$4.)

Médicaments microbiens. Bactériothérapie. vaccination, sérothérapie. Par les docteurs Metchnikoff, Sacquépée, Remlinger, Louis Martin, Vaillard, Dopter, Besredka, Wassermann, Leber, Dujardin-Beaumetz, Salimbeni, Calmette. Avec 26 figures dans le texte. Paris: J. Baillière et fils, 1909. Pp. xii-400.

Obstetrical and Gynæcological Nursing. By Edward P. Davis, A. M., M. D., Professor of Obstetricis in the Jefferson Medical College, Philadelphia; Obstetrician to the Jefferson Hospital, etc. Third Edition, Thoroughly Revised. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 436. (Price, \$1.75.)

pany, 1908. Pp. 430. (Price, \$1.75.)

Refraction of the Eye. By Harry C. Parker, M. D., Clinical Professor of Ophthalmology, Indiana University School of Medicine, Indianapolis, etc. With One Hundred and Six Illustrations. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 201. (Price, \$1.25.)

A Textbook of Diseases of Women. By Charles B. Penrose, M. D., Ph. D., Formerly Professor of Gynæcology in the University of Pennsylvania; Surgeon to the Gynæcoan Hospital, Philadelphia. With Two Hundred and Twentyfive Illustrations. Sixth Edition, Revised. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 550. (Price \$2.55.) (Price, \$5.25.)

Transactions of the Thirtieth Annual Meeting of the American Laryngological Association, held at Montreal, Canada, May 11, 12, and 13, 1908. New York: Published by the Association. Pp. 421.

Official Rews.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending November 6, 1908:

| Smallpox | United | States. | | |
|-----------------------------------|--------|------------|-------|------------|

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending October 28, 1908.

ANDERSON, JOHN F., Passed Assistant Surgeon. Granted seventeen days' leave of absence from November 5, 1908.

BAILEY, C. W., Acting Assistant Surgeon. Granted four-teen days' leave of absence from October 21, 1908. CARRINGTON, P. M., Surgeon. Leave granted October 6,

1908, for six days, amended to read four days, en route to join station

COMFORT, N. C., Pharmacist. Reassigned to duty, Quaran tine Service, Philippine Islands, to date from February

7. 1008. CREEL, R. H., Passed Assistant Surgeon. Directed to reor temporary duty in the Hygienic Laboratory, November 1, 1908.

EAGER, J. M., Assistant Surgeon General. Detailed to represent the Service upon the Committee on Revision of

the Nomenclature of Diseases, American Public Health Association.

ELDREDGE, M. B., Pharmacist. Granted seven days' leave of absence from October 24, 1908, under paragraph 210, Service Regulations.

GRIMM, R. M., Assistant Surgeon. Directed to proceed to Chicago, Ill., and report to medical officer in command of Marine Hospital for duty and assignment to quar-

IRWIN, FAIRFAX, Surgeon. Upon being relieved by Surgeon R. M. Woodward, directed to proceed to Arundel Cove, Md., and report to commanding officer of the

Revenue cutter Snohomish for duty.

Kerr, J. W., Assistant Surgeon General. Granted two days' extension of leave of absence from October 23, 1908.

LAVINDER, C. H., Passed Assistant Surgeon. Directed to proceed to Columbia, S. C., upon special temporary

Lyall, Robert, Acting Assistant Surgeon. Granted five days' extension of leave of absence from October 17,

days extension of factors of the state of th

to duty at Immigration Station, Ellis Island, N. Y., to date from March 12, 1908.

NAULTY, C. W., Jr., Acting Assistant Surgeon. Granted three days' leave of absence from October 19, 1908.
ONUF, B., Acting Assistant Surgeon. Granted twenty-seven days' leave of absence from November 1, 1908.
PREBLE, PAUL, Assistant Surgeon. Directed to report to the

medical officer in command at Marine Hospital, Baltimore, Md., for duty and assignment to quarters.

RIDLON, JOSEPH R., Assistant Surgeon. Directed to report to the medical officer in command at Marine Hospital, Stapleton, N. Y., for duty and assignment to quarters. Robinson, D. E., Passed Assistant Surgeon. Granted one

month's leave of absence from November 5, 1908. SMITH, F. C., Passed Assistant Surgeon. Directed to report for temporary duty in the Hygienic Laboratory,

November I, 1908. Sweet, E. A., Passed Assistant Surgeon. Leave of absence for two months from August 18, 1908, amended to read two months from August 25, 1908. Granted one month's leave of absence from October 25, 1908, on account of sickness

Wertenbaker, C. P., Surgeon. Detailed to represent the Service at the meeting of the Virginia State Medical Society at Richmond, Va., October 22, 1908.
WILLIAMS, L. L., Surgeon. Directed to proceed to Boston, Mass., and assume command of the Service.

Woon, CHARLES E., Assistant Surgeon. Upon arrival of Assistant Surgeon R. M. Grimm at Chicago, Ill., directed to proceed to Baltimore, Md., and report to the commanding officer of the Revenue cutter Seneca for

Woodward, R. M., Surgeon. Upon being relieved by Surgeon L. L. Williams, directed to proceed to Detroit, Mich., and assume command of the Service.

Appointments.

Dr. Paul Preble commissioned (recess) as Assistant Surgeon in the Public Health and Marine Hospital Service, October 20, 1908.

Dr. R. M. Grimm commissioned (recess) as Assistant Surgeon in the Public Health and Marine Hospital Service,

October 20, 1908.

Dr. Joseph R. Ridlon commissioned (recess) as Assistant Surgeon in the Public Health and Marine Hospital Service, October 20, 1908.

Board Convened.

Board of medical officers convened to meet at the Marine Hospital, San Francisco, Cal., November 9, 1908, for the purpose of making a physical examination of a captain and a lieutenant of engineers of the Revenue Cutter Service. Surgeon H. W. Austin, chairman; Passed Assistant Surgeon W. W. King, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers of the Medical Corps of the United States Army for the week ending November 7, 1908:

DUTCHER, B. H., Major, Medical Corps. Arrived at Platts-burg Barracks, N. Y., for duty.

EBERT, R. G., Lieutenant Colonel, Medical Corps. Granted leave of absence for ten days.

LA GARDE, L. A., Lieutenant Colonel, Medical Corps.
Granted leave of absence for one month.

LAMSON, THEODORE, Captain, Medical Corps. Leave of ab-

sence extended one month. LE HARDY, J. C., First Lieutenant, Medical Reserve Corps.

Relieved from temporary duty at Fort Casey, Wash., and ordered to return to his proper station, Fort Lawton, Wash.

Morse, C. F., Captain, Medical Corps. Granted leave of absence for one month, to take effect about November 23, 1008

PATTERSON, R. U., Captain, Medical Corps. Relieved from duty in command of Company A, Hospital Corps, and ordered to report to the commanding general, Army

of Cuban Pacification, for assignment to duty,

Albort, E. M., Captain, Medical Corps. Assigned to duty
as commanding officer, Company A, Hospital Corps,
and ordered to proceed to Fort D. A. Russell, Wyo.

Navy Intelligence:

Official list of changes in the stations and duties of officers of the medical corps of the United States Navy for the week ending November 7, 1908:

BOGERT, E. S., Jr., Surgeon. Detached from the Naval Recruiting Station, New York, N. Y., and ordered to the Marine Recruiting Station, New York, N. Y.

BUCHER, W. H., Surgeon. Granted sick leave for three months, when discharged from treatment at the Naval Hospital, Las Animas, Colo.

DESSEZ, P. T., Passed Assistant Surgeon. Detached from the South Dakota and ordered to the Pacific Fleet, will be from Son Exempleshed.

sailing from San Francisco about December 5th.
Norton, O. D., Surgeon. Detached from the Marine Recruiting Station, New York, N. Y., and ordered to the
Naval Recruiting Station, New York, N. Y.
Stepp, J., Passed Assistant Surgeon. Detached from the

Denver and ordered home to await orders.

Von Wedekind, L. L., Surgeon. Detached from the Ala-

bama and ordered to the South Dakota.

Births, Marriages, and Deaths.

Married.

AUFHAMMER-Corey.-In Downingtown, Pennsylvania, on Monday, November 2d, Dr. Charles Howard Aufhammer and Miss Ada B. Corey.

Heiman—Henry.—In Baltimore, Maryland, on Wednesday, November 4th, Dr. Jesse Heiman, of Syracuse, New York, and Miss Louise Henry.

HIGGINS—MULVEY.—In Philadelphia, on Wednesday, October 28th, Dr. Joseph F. Higgins and Miss Mary Irene Mulvey.

Lawson—Love.—In Washington, D. C., on Saturday, November 7th, Dr. James Francis Lawson and Miss Lula Emma Love.

Died. BILLE.-In New Orleans, Louisiana, on Tuesday, October 27th, Dr. Waldemar Bille, aged seventy-three years.
CALLAHAN.—In Boston, on Thursday, October 29th, Dr.
Joseph Thomas Callahan, of Woburn, Massachusetts, aged

thirty-five years. CORCORAN.-In Brooklyn, on Thursday, November 5th,

Dr. Walter J. Corcoran, aged fifty-two years.
Davis.—In Colonia-Pachico, Mexico, on Friday, October 23d, Dr. Samuel T. Davis, of Lancaster, Pennsylvania.
Doherty.—In Chicago, on Tuesday, October 27th, Dr.

DOHERTY.—In Chicago, on Tuesday, October 27th, Dr. David Joseph Doherty, aged fifty-eight years.
FOWLER.—In Brooklyn, on Friday, October 30th, Dr. Chauncey B. Fowler, aged sixty years.
GILDAY.—In New York, on Thursday, November 5th, Mrs. Walter C. Gilday, wife of Dr. Walter C. Gilday, aged thirty-three years.

hirty-three years.

GILLETTE.—In New York, on Saturday, November 7th,
Dr. Walter R. Gillette, aged sixty-seven years.

JACKSON.—In Fall River, Massachusetts, on Tuesday, October 27th, Dr. John H. Jackson.

KOHLER.—In New Holland, Pennsylvania, on Saturday, October 31st, Dr. John B. Kohler, aged fifty-seven years.

October 31st, Dr. John B. Kohler, aged fitty-seven years. LEWIS.—In Fayetteville, Arkansas, on Sunday, November 1st, Dr. F. L. Lewis, aged sixty-seven years.

MACGILL.—In Frederick, Maryland, on Thursday, October 30th, Dr. Lloyd T. MacGill, aged seventy-nine years.

O'NEILL.—In Syracuse, New York, on Wednesday, November 4th, Dr. John O'Neill, aged twenty-three years.

PARKER.—In Chicopee, Massachusetts, on Thursday, October 20th, Dr. Francis E. Parker, aged thirty-eight years.

REHFUSS.—In Philadelphia, on Saturday, October 31st,

Dr. Emil G. Rehfuss, aged forty-seven years.

REHFUSS.—In Philadelphia, on Saturday, October 31st, Dr. Emil G. Rehfuss, aged forty-seven years.
Sahin.—In Kansas City, Missouri, on Sunday, November 1st, Dr. Almer L. Sabin, aged fifty-seven years.
Steickler.—In Colorado Springs, Colorado, on Monday, October 26th, Dr. William M. Strickler, aged seventy years.
VARY.—In Chicago, on Wednesday, October 28th, Dr. William E. Vary, aged eighty-one years.

THE NATURE OF CARCINOMA IN GENERAL, AND THE EARLY DIAGNOSIS OF GAS-TRIC CARCINOMA.*

> By JAMES M. ANDERS, M. D., LL. D., Philadelphia,

Professor of Medicine and Clinical Medicine of the Medico-Chirurgical College; Consulting Physician to the Jewish Hospital;
Consulting Physician to the Widener Home for Crippled Children, Etc.

While it may appear to my hearers to have been inexpedient to select a subject which has been the theme of inquiry by so many men of mark, no one can, for a moment, impugn its absolute worthiness and transcendent practical interest and importance.

From the standpoint of treatment, it is all important that an early recognition of gastric carcinoma be rendered feasible and practicable. The treatment has been rescued from mere empiricism by the art of surgery, but clinicians have in the past been unable to demonstrate its existence in the incipient stage. The writer is of opinion that more substantial progress in the clinical study and investigation of this disease, especially from an ætiological viewpoint, would occur if a definite hypothesis as to its nature were more universally adopted.

A theory, if it were applicable to all the known facts bearing upon the cancerous process in general, would attract a host of followers and most probably lead to the discovery of important fundamental truths, as well as to correct generalization regarding the pathogenesis of the disease. Such a theory would naturally stimulate thought and investigation, but it would as naturally fall to the ground as soon as confronted by real contradictory evidence, or, in other words, upon being found to be defective. This matter of the crystallization of the thought and investigations concerning carcinoma into one har-monious theory would result in advancement and achievements in the way of practical results hitherto unparalleled.

Recent personal observation joined with certain theoretical considerations have led to the conviction that all the ascertained facts relating to gastric carcinoma harmonize with the microbic theory of disease. The clinical and pathological phenomena observed are clearly referable to a common origin, a bacillus or parasite. Indeed, many experimentalists have taken cognizance of this truth and taken their bearing accordingly, so that eminently satis-

factory expositions of the general subject are to be found in recent medical literature. Unfortunately, however, the medical profession is still confronted with a mass of conflicting views and hypotheses.

It must not be understood from a mere statement of the general proposition that we have definite proof of its accuracy, for, if that were true, it would at once pass beyond the realm of hypothesis into that of established fact. It has been well said that astronomy is everlastingly indebted to the Newtonian hypothesis of gravitation, and chemistry no less to the atomic theory. A proper conception of these fundamental truths constituted the basis of a working hypothesis, whose results fairly revolutionized science. It is earnestly to be hoped that a rational system of investigation be widely adopted in the study of carcinoma; this should be produced and fastened upon with energy to supersede the variable methods in vogue at date of writing. am not promulgating any new idea, but merely attempting to indicate the necessity for the formulation of a safe, acceptable theory with a view to bringing about concentration of professional effort and energies. What is needed, then, to reduce the problems involved to rigid scientific scrutiny is general and united action.

I would here briefly state a series of facts, which show that the disease under consideration and microbic diseases as a class are identical as to cause and operation. These are: (1) Successful transplantation of malignant tumors in mice, rats, and dogs (Hanan, Loeb, and others). (2) Contagiousness of carcinoma in human beings as shown by transference of the virus by means of instruments, e. g., carcinoma developing along the track of the trocar which has been used to relieve ascites in hepatic carcinoma. (3) By artificial selection, the virulence and transmissibility of a given strain can be increased (Ehrlich). (4) Toxines which are most probably bacterial are generated in carcinoma. (5) Presence of Plimmer's bodies, and of a spirochæta, which is more plentiful in the actively growing portions of the tumor. (6) The ability to immunize mice with a serum and to cause resorption of small tumors in some cases (Jensen, confirmed by Ehrlich). (7) The discovery in a certain fungus of the intermediate host of the protozoan parasite of carcinoma, and the power to inoculate with cultures grown on the mucor racemosus with the production of malignant tumors, which seem to be identical with those described by Jensen; their malignant character confirmed by the microscope, by their transmissibility, by transplantation of cells to other individuals

of the same species, and by the development of me-

"The address in medicine, read before the Pennsylvania State Medical Society, September 15, 1908.

tastases (Schmidt) (1). (8) An actively growing mouse tumor can at times be transplanted to rats, where it will grow luxuriantly for a week or ten days until antibodies are formed, when growth ceases and it becomes necrotic and is sloughed off or is absorbed; such rats are immune to subsequent inocu-(9) Experimental evidence that immunity is secured in certain affected animals by the development of some immunizing substances which enable the organism to resist carcinoma either temporarily or permanently (spontaneous cure). (10) General and local reactions occurred in cancerous patients following the injection of killed pure cultures of the parasites; the reaction was absent in healthy subjects (Schmidt). (11) A cage has been shown to be the source of infection of upward of sixty cases of tumors in white mice. Moreover, in certain breeding establishments carcinoma occurs endemically (Gaylord and Clowes, and others). (12) The prevention of transmission by contagion through sterilization of cages in which infected rats had been kept (Gaylord and Clowes) is highly suggestive. (13) Loeb calls attention to the endemic occurrence of carcinoma of the inner angle of the eye among cattle on a ranch in Wyoming, while neighboring ranches were practically free from the disease. (14) Epidemics of carcinoma in certain towns and the peculiar distribution of cancerous cases in certain (15) So called "cancer houses" for human beings have probably been proved to be a source of infection (Loeb, Borrel). (16) The combination of the characteristic pathological changes, including metastases and the clinical symptoms and course, points strongly to the infectious nature of carcinoma. (17) Autolysis of a recurrent carcinomatous nodule of the breast (Simon), and improvement in general health and strength from the use of injections of anticancer serum in inoperable carcinoma of the breast, pancreas, and pylorus (v. Leyden).

The foregoing results of observations by different competent investigators, who have labored with sustained earnestness of purpose, strikingly confirm the hypothesis here promulgated. There are a number of diseases which are universally regarded as infectious because the contagion is known to be there, e. g., measles, smallpox, but the specific germs have not as yet been isolated. Moreover, the profession now universally recognizes the existence of predisposing factors in the causation of carcinoma. These are previous injury or ulcerations or abrasions of the skin and mucous surfaces.

In this connection the views of Mayo Robson concerning the influence of such cutaneous and mucous lesions as precancerous states are significant. He writes: "In certain situations precancerous conditions can be readily recognized; this especially applies to the tongue, lips, larynx, uterus, and the skin, suggesting strongly that cancer is a new implantation on a prepared ground; probably, if we could only find it, every cancer, whether external or internal, follows on a precancerous condition, such as cancer of the gallbladder on ulceration produced by gallstones, cancer of the stomach on chronic gastric ulcer, epithelioma of the penis on irritation under a phimosis, cancer of the bladder on papilloma or on ulcers due to calculi, and cancer of the rectum and colon on stercoral or other ulcers" (2).

Surely, the field of investigation under discussion is fertile and promising for the future and one that should stir the energies of all investigators in search of truth, of all things upon earth the most precious. Incidentally, it might be justly argued that the facts transmitted to us as the outcome of the prolonged studies of the observers cited above indicate the necessity for the enforcement of isolation and sterilization in the treatment of human cancer cases.

EARLY DIAGNOSIS OF GASTRIC CARCINOMA.

The greatest strides made in recent times in the recognition of early cases of gastric carcinoma have been limited to the laboratory and surgical phases of the subject. The clinical significance of the laboratory findings, however, differs according to different observers; they are not to be isolated from the symptoms and course of the disease, but judiciously balanced and compared with the clinical characteristics and the steady progression with occasional slight remissions of the disease. Chase says: "Those who suppose that a positive or negative diagnosis may be made on the strength of the chemical examination of the gastric juice, should at once disabuse themselves of this idea."

The grouping of features which renders a given case suspicious is not constant. The closest scrutiny of all the symptoms, signs, and laboratory findings, as well as the most judicious balancing of the data entering into the previous history by an eminently skilful diagnostician, is an absolute necessity before a probable diagnosis can be reached.

The general practitioner who fails to avail himself of an expert medical opinion in cases in which he has the slightest reason to suspect this disease, is scarcely alive to his responsibilities and obligations to his patients. It is deplorable, but nevertheless true, that carcinoma cases are too often permitted to reach an advanced stage before expert services, usually surgical, are sought after. Touching the infrequency of early diagnosis, a lack of thorough, systematic study at short intervals is also a factor that plays an influential part. The practitioner should recognize an added necessity for early diagnosis; to wit, while radical extirpation or partial gastrectomy is advisable in early cases and offers promise of more or less aid, late operations, too often undertaken, almost invariably serve to hasten death. Much has been said in recent medical literature, not without cause, about useless gastric surgery; it is in a measure, at least, the result of too little time being allowed for carrying out medical means of diagnosis. In this connection Stone (3) pertinently remarks: "There probably will continue to be found much wisdom in the old adage, which refers to making haste slowly, for otherwise surgery will suffer the reaction which always accompanies the less careful diagnosis of cases in the enthusiasm of prospective cure."

Regarding the anamnesis, it is to be recollected that there is often a discoverable element of relationship existing between gastric carcinoma and ulcer. If there is a clear history of previous ulcer, this fact bears tremendously upon the case, and should tend to strengthen the slightest ground for suspicion in the mind of the examiner. The so called precancerous stage is now easily recognized

in a considerable proportion of the cases. From the operating theatre and deadhouse come reliable recent statistics to the effect that carcinoma develops from chronic ulcer in upwards of one half of all

It is not my purpose, however, to show the frequency of this carcinomatous implantation upon ulcer, an aspect of the question that has been dealt with by others, notably by my distinguished colleague, Rodman (4), but rather to emphasize the importance of its recognition and urge either extirpation or gastroenterostomy whenever ulcer proves rebellious to medical treatment. More lives are thus savable than by operation, however early performed in the course of carcinoma. Before leaving this branch of my subject, it should be pointed out that Mayo and Franklin (5) found "in an experience of 1,112 duodenal and gastric operations, only one instance in which carcinoma had developed upon the base of a duodenal ulcer. That carcinoma of the duodenum, however, is rare no longer admits of a rational doubt.

The early symptoms in cases of carcinoma originating in ulcer display certain distinctive peculiari-Now that the frequent association of the two processes, carcinoma and ulcer, is well recognized, the symptomatology of carcinoma, especially that portion pertaining to the laboratory findings, requires recasting. When malignant degeneration of a gastric ulcer sets in, both dietetic regulations and medicinal treatment at once fail to relieve the subjective symptoms, which, therefore, persist and become aggravated with the progress of the case. Pain is apt to increase in intensity, and it may either continue to exacerbate into distinct paroxysms or radiate to the thorax (ribs) and upper lumbar region. A dislike, or even loathing, for food develops almost as soon as the cancerous process commences. Hyperchlorhydria is present and may be pronounced; on the other hand, achlorhydria is perhaps oftener found, and, if known to have been preceded by hyperchlorhydria, becomes at once of the utmost diagnostic importance.

Hæmatemesis may occur early, and recur at more frequent intervals, particularly occult bleedings, in carcinoma grafted upon ulcer. The general features likewise undergo modification; there ensues progressive wasting, anæmia, and debility, which should early arrest the attention of the clinician. According to my observation, the complexion soon assumes a somewhat muddy hue.

The foregoing changes in the clinical picture should excite suspicion of beginning carcinoma and lead to exploratory operation. It should be emphasized that the wasting is not invariably progressive and the same is equally true of the anæmia. In a case under my cate recently a gain of five pounds in bodily weight was noted and maintained for a period of three months; this was followed by rapid emaciation and death at the end of two months. The carcinomatous nature of some cases, which presented all of the classic features of gastric ulcer, is sometimes first revealed by an examination of the growth following operative intervention. Clinicians must in future concern themselves with the subject of the prevention of carcinoma through the timely removal of this potent, predisposing factor; it is due

the public to receive the benefits of our accumulated knowledge in this respect.

The mode of onset of gastric carcinoma as an idiopathic affection presents a somewhat different clinical picture, though variable in different cases according as it involves the pylorus, cardia, or fundus of the organ. In this form the principal subjective complaints are too vague and indefinite to be of diagnostic service. If, however, anorexia and pyrosis develop somewhat abruptly and lead to loss of weight and vigor and early anæmia, gastric carcinoma should be thought of and further observations both from the clinical and laboratory side should be promptly made. Epigastric pain is present in about eighty-five per cent. of cases; it is dull and boring in character, more continuous and less subject to exacerbations than in ulcer, as a rule, and more severe than in chronic gastritis. In carcinomatous stenosis of the pylorus the pain may soon become cramplike in character due to peristalsis. Although far from common, pain may be reflected to the left subscapular region. Strictly, pain rarely becomes sufficiently marked to attract attention during the incipient stage of the disease.

the pylorus, leading to rapid stenosis, but not, as a rule, until after pain has persisted for a considerable period, hence is of less diagnostic importance than the latter symptom in the incipient stage. Neither is it so characteristic with regard to frequency of occurrence, and the character of the vomitus, as at a later stage when large amounts of offensive decomposing material are ejected. It is to be recollected, however, that evidence of gastric stagnation, even though of moderate degree, is one of the few cardinal symptoms of the beginning of this grave

Occasional vomiting may be noted in carcinoma of

disease. In carcinoma of the cardia, mere regurgitation of solid food, almost immediately after it is ingested, is highly significant and it is associated with rapid wasting, anorexia, pyrosis, decided early anæmia, and loss of vigor. The vomiting of blood occurs in about one third of the cases, but hæmatemesis is not an initial symptom, being due to ulceration of the new growth, and hence practically valueless for diagnosis of early cases, particularly in the scirrhous variety.

Among instrumental aids to the early recognition of gastric carcinoma, the Röntgen rays take a prominent place. By this means an expert can ascertain not only the size and position of the stomach to a nicety, but also the degree of motility, the amount of accumulated gas, and any retention of food that may be present. More than this, the Röntgenologist can detect the presence of a new growth often before it can be palpated. Such studies have been made by a number of investigators, prominent among whom are Holzknecht, Jonas (6), and Pfahler (7).

To an expert a new growth makes itself evident by a change in the contour of the stomach wall; by disturbances of the peristaltic waves at certain points; at times by rigidity and contraction of the stomach wall; by adhesions which prevent the free motility of the stomach when the abdominal walls are contracted, or when the position of the patient is changed; and, finally, in some cases, by obstruction to the passage of food.

A brief narration of a case in my service in the

wards of the Medico-Chirurgical Hospital, Philadelphia, will serve to illustrate this method of investigation.

The patient, Mr. J. B., aged sixty-seven, was admitted May 7, 1908. For a year previously he had suffered from nausea and occasionally vomiting, which occurred soon after taking food. In the middle of December, 1907, he began to vomit blood streaked mucus, the emesis being usually preceded by pain. He complained of constant eructations of gas, and had lost thirty pounds in weight in six months. Gastric analysis showed no free hydrochloric acid, but a trace of combined hydrochloric acid. Neither lactic nor butyric acids were present. There was no abdominal tenderness and no palpable tumor, but the area of gastric

tympany was much diminished.

The x ray examination, made by Dr. G. E. Pfahler, showed the stomach to be extremely small, not holding showed the stomach to be extremely shall be over ten ounces. The food passed out of the pylorus as fast as it entered at the cardiac orifice, showing that the pylorus was abnormally patulous. The stomach was situated abnormally high; could not be moved by the muscular contractions of the abdomen; could not be distended, and showed no peristaltic waves; all of which conditions indicated that the walls of the stomach were rigid and adherent and most probably infiltrated with carcinoma. The first six inches of the duodenum were found to be dilated; this was thought to be produced probably by either adhesion or infiltration of the duodenum. An exploratory operation performed three days later by Dr. W. L. Rodman confirmed the above findings. A duodenojejunostomy was performed.

I need not refer to palpable tumor, believing as I do that this belongs to a more advanced stage than that which is being considered in this discussion. It is true, unfortunately, that sufferers from gastric carcinoma often fail to present themselves to a physician for examination and treatment until tumor and most of the other characteristic features are in evidence

Gastric lavage may prove a valuable diagnostic aid in cases in which stagnation occurs early, enabling, as it does, the clinician to determine the character of the retained stomach contents, which in carcinoma often show decided evidences of decomposition. A physical examination often reveals early epigastric rigidity, a sign of decided importance. Ackerman and Gompertz (8) have found on microscopical examination that, in stagnation of the fasting stomach contents, Oppler-Boas bacilli replace lactic acid and sarcinæ. The precise worth of this test in early cases is unknown, but is most probably inconsiderable. Of greater diagnostic value is the detection of pus cells on microscopical examination of the gastric contents. In the first stage of the form of gastric carcinoma under consideration, free hydrochloric acid is diminished, but is not absent until nearly or all of the cardinal features put in an appearance, or at a much later period of the disease.

A progressive decline in the percentage of free hydrochloric acid for a month or longer, as determined by an analysis of the stomach contents at intervals of a few days, is strongly corroborative of this disease. In this connection, the importance of the work of Benjamin Moore (9), who first showed that diminished secretion of free hydrochloric acid also occurs in carcinoma located in other organs than the stomach, can not be overrated. Diminished gastric acidity is further noted in many noncancerous conditions, so that carcinoma of the stomach exercises no specific influence on the acid secreting power

of this organ.

It is to be emphasized, however, that the reduction

in the percentage of free hydrochloric acid is more striking and more constantly progressive in gastric carcinoma than in other conditions. Traces of lactic acid may be present in incipient malignancy, but, as a rule, this substance is first detectable long after the close of this stage of the affection.

Occult blood in the stomach contents and stools, which does not occur in healthy subjects, is almost uniformly present in this disease, but, according to personal experience, not so constantly as could be desired in the early stages. Occult hæmorrhages also occur, though less frequently, in gastric ulcer and in simple hyperchlorhydria. The foregoing facts go to show that occult bleedings when present possess mere confirmatory value in early diagnosis.

Gastroscopical examination has been advocated for the early detection of carcinoma of the stomach. Chevalier Jackson (10) offers gastroscopy as a substitute for an exploratory operation in cases in which the patient declines to submit, "or in which the surgeon or the physician considers a simple procedure almost free from risk preferable to operative ex-Unfortunately, there is still a large and ploration." unexplorable area by this means, although the fundus and the pyloric ends can be brought within range of the gastroscope by the assistance of an expert abdominal manipulator. While the results thus far obtained from gastroscopy are decidedly meagre, its usefulness could be greatly increased as the result of increased skill and practical knowledge. The blood manifests no distinctive features in the earlier stages. With the progress of the disease, certain findings, such as an unusually low color index, marked reduction of the erythrocytes and leucocytosis, in which the polymorphonuclear cells are especially increased, are in evidence.

Certain ætiological factors deserve to be taken into account. Heredity can be traced in about ten per cent, of the cases. While the influence of heredity is undoubted in some instances, its potency as a causative factor is often overemphasized by medical writers. It should not be held to exercise a causative influence in a given case, unless multiple cases have occurred among the ancestors.

Age is a well established, predisposing cause, seventy-five per cent. of 2,038 cases analyzed by Welch having occurred between the fortieth and seventieth years. On the other hand, the disease is far from uncommon prior to the thirtieth year, e. g., in 2.8 per cent, of Welch's series of cases (quoted above), and 2.5 per cent. in 1,069 cases collected by Osler and McCrae (11). Again, there are valid records of six cases, at least, before the tenth year.

While I think practitioners, as a class, should guard against the mistake of attempting to arrive at an early positive diagnosis before requesting surgical aid, it is undeniably true that the services of the expert diagnostician are required first and foremost to detect the clinical indications on which a reasonable suspicion may be founded. Indeed, one of the most important means at our disposal with which to clear the diagnosis of dubious cases, and one not to be lightly regarded, is surgical exploration. W. J. Mayo has well said: "A suspicion of cancer of the stomach, which can not be dissipated by known methods within a short time, should lead to exploration." Of 313 operative cases, he found KNOTT: IRON.

that only twenty-six had been diagnosticated early enough to permit of radical extirpation. This fact alone should tend to stimulate clinicians to the greatest activity in their efforts to detect the earliest clinical manifestations on which a probable diagnosis or a justifiable suspicion calling for surgical inter-

vention, can be based. In the presence of the following grouping of features and conditions, or even a majority of the same, an exploratory operation should be advised to be followed by radical extirpation in case the new growth be encountered: (1) If the patient's age is between the forty-fifth and seventieth years, the period of life in which carcinoma develops in the majority of cases. (2) If slight or moderate indications of secondary gastrectasis exist, confirmed by x ray and physical examinations. If the chemical examination repeatedly during the course of three or four weeks shows marked subacidity or absence of hydrochloric acid and particularly if lactic acid be also found. (4) If there is wasting without other assignable cause or causes, and moderate anæmia with low color index and possibly leucocytosis. (5) If the condition resists treatment for several weeks. (6) If epigastric rigidity is present. (7) If a constant positive blood reaction is given by the stools with good motor functioning on the part of the stomach and neither free hydrochloric nor lactic acid be present (Osler).

Carcinoma should, however, not be made to cover mere groups of gastric manifestations. There must be a close and systematic scrutiny of individual symptoms and a subsequent correlation of the same, and to this end the services of an expert diagnostician are required. The study of these cases must be conducted on broad lines and the various refined diagnostic methods before referred to, e. g., x ray examination, chemical tests, microscopical studies, and the like, must never be omitted.

While the laboratory and other tests may prove nothing, they are of confirmatory value if systematically repeated. Moreover, chemical examinations of the stomach contents are to be repeated systematically at intervals of a few days for a couple of weeks or even months, in which case they may, if the results are fairly uniform, support and strengthen the inferences to be drawn from the rational symptoms and signs, thus forming a grouping of features upon which incipient carcinoma may be justly suspicioned. The tests must be made by one who has expert knowledge of the subject of laboratory methods and technic, one who is also a careful, trustworthy worker. It would be unwise to attempt to establish a time limit for making a diagnosis; this period must be variable for individual cases depending on many circumstances, e. g., differences of regional selection of the new growth, the pathologic variety of carcinoma present, and the like, but it should not exceed four to six weeks as a

Again, since there is no assemblage of diagnostic features that enable the clinician to recognize with certainty the early organic changes in carcinoma of the stomach, he must, nevertheless, before proceeding to a final judgment, attempt a careful and painstaking differentiation from other gastric affections, e. g., gastric ulcer, chronic gastritis present-

ing symptom groups bearing a more, or less close resemblance to carcinoma.

Finally, an early diagnosis by medical methods in the present state of our knowledge is out of the question, but it is practicable, save only in cases marked by extreme latency, to assume the existence of strong suspicions by weighing the available facts and data. Under these circumstances, delay in the matter of requesting the application of surgical means is inexcusable in view of the amenability of incipient malignancy to surgical art, in some cases, at least.

IRON:

Metallic and Magnetic, Physical and Philosophical; Its Place in Mythology, in Demonology, in Astrology, in Medical and Surgical Therapeusis.

By JOHN KNOTT, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A., Etc., Dublin, Ireland.

(Continued from page 928.)

The other most conspicuous physical characteristic of the mineral loadstone is, of course, its polarity; and it is difficult to conceive how it can have successfully escaped the notice of all the natural philosophers and practical navigators of the Mediterranean borders down through all the centuries of their radiant classical enlightenment, although we are told there is but one extant classic phrase which can possibly be forced, or twisted, into a "magnetic polar" reference; the Hic ventus jam secundus est cape modo versoriam of Plautus. It need hardly be added that the majority of literary critics and historians of science do not accept the view that the "versoriam" of the early classic really referred to a ship's compass; while the average many are content to leave the credit of the invention of the mariner's "carde" with the Chinese, and the semiinspired few would claim the recognition for the all knowing Solomon of having (in common with every other existing item of human knowledge, physical and metaphysical) adapted his inspired familiarity with the properties of the loadstone to the enrichment of his kingdom, the beautification of his metropolis, and the ultimate glorification of the God of Israel. For—did he not send forth his ships on a three years' voyage unto Ophir, and how could an ocean pilgrimage which occupied so long a period be successfully conducted without the aid of a mariner's compass???

A curious mediæval idea which must have originally been evolved in this connection, was correborated by the famous Spanish Jesuit, Eusebius Nierembergius; and is thus noticed (and commented on) by Sir Thomas Browne: "that the body of man is magneticall, and being placed in a boate, the vessell will never rest untill the head respecteth the north; if this be true, the bodies of Christians doe lye unnaturally in their graves, and the Jews have fallen upon the natural position, who in the reverence of their temple, do place their beds from north to south."

The physical peculiarity manifested in the mutual influence of the mineral loadstone and the metallic iron must have strongly impressed the observant "Father of Medicine" himself, who refers to it in the forcible phrase: λίθος δστις τὸν σίδηρον άρπάξει (lapis qui ferrum rapit). And his great apostolic exponent (Claudius Galen) uses the almost correspondingly emphatic verb Eductiv. The language of Aristotle, on the other hand, displays the descriptive moderation which characterizes the sage philosopher: λίθος ὅστις τὸν σίθηρων κινὲι (lapis qui ferrum movet.) And his master, the "divine" Plato, refers to it in language of wondering appreciation: θεία δὲ δύναρις, ή σε χίνει, ώσπερ ἐν τῆ λίθο, ήν; Εθριπιδής μὲν Μαγνήτιν ἀνόρασεν, όι δὲ πόλλοι. Ηραχλείav. Significantly distinctive, too, of theological hyperbolization is the term used in the descriptive reference of St. Augustine: mirabilem ferri raptorem; while the more philosophically critical St. Thomas Aquinas refers to the loadstone in language more suggestive of the manner of the immortal Stagirite. who was his acknowledged master in logical discrimination as well as in metaphysical method. The tendency to modern innovation regarding the physical theories and descriptions so long preserved by the protection of authority is rather significantly indicated in the words of the "Father of Modern Philosophy": Præterea magnes trahet ferrum, sive potius magnes & ferrum ad invicem accedunt, neque enim ulla ibi tractio est. This view of Descartes was much more emphatically enunciated by Cabeus: Nec magnes trahit proprie ferrum, nec ferrum ad se magnetem provocat, sed ambo pari conatu ad invicem confluent. Similar to these views was that of the "Father of Magnetism" himself, who names the phenomenon coitio (Gilbert, De Magnete, 1600); and describes it (as Sir Thomas Browne approvingly observes) as "not made by any faculty attractive of one, but a syndrome and concourse of each; a coition alway of their vigours, and also of their bodies, if bulke or impediment prevent not, and therefore those contrary actions which flow from opposite poles or faces, are not so properly expulsion and attraction, as sequela and fuga, a mutuall flight and following." And this latter critical and accomplished knight errant of "truth and right" versus antiquity and authority also

points out that: "Concordant hereto is the assertion of Doctor Ridley, physition unto the emperour of Russia, in his Tract of Magnetical Bodies; defining magneticall attraction to be a natural incitation and disposition conforming unto contiguitie, an union of one magneticall body with an other, and no violent haling of the weak unto the stronger."

Although the celebrated author of the Religio Medici could himself be very credulous when cogitating on matters divine-or rather, let us say, diabolical—as is well shown by his emphatic opinions on the reality of witchcraft and the existence of a personal devil, his knowledge and teaching on the subject of the Magnet were far in advance of those of his junior medical-and hypercritical-contemporary, Gideon Harvey; who, also, had taken all knowledge for his province. So he judiciously corrects the classic fable, repeated so gravely by Pliny and by Serapion, of its pulling ships to pieces (or to the bottom of the sea, directly) by attraction of their iron nails and bolts; also the stories of the influence of the diamond on a needle touched therewith, and on a magnetic pole which it was used to screen. The former of these had been stated by the famous natural magician, Baptista Porta, to be quite similar to that of the loadstone; while the latter effectively neutralized the attraction. And both statements are contradicted by Browne, although he does not indicate the very probable origin: that the classic adamas (equivocally) referred to the magnet in some authors, and to the diamond in others. He also corrects the mediæval misstatement of Lælius Bisciola, to the effect that "if unto ten ounces of loadstone one of iron be added, it encreaseth not unto eleven, but weights ten ounces still: a relation inexcusable"; that of "Beda his relation of the loadstone that attracted onely in the night"; and rules out the "inexcusable" suggestion of "Franciscus Rueus, a man of our own profession, who "is fain to salve as impostures of the Devill" some of those "traditionall qualities." He also rejects the statement of Paracelsus "that if a loadstone be annointed with mercuriall oyle, or onely put into quicksilver, it omitteth its attraction forever" (a statement which had been respectfully recognized by Gideon Harvey); and the fascinating fables which had been so long received regarding the magnetic suspension of the tomb of Mahomet, of the statue of Arsinoe, of that of Bellerophon's horse, and of the chariot in the temple of Serapis.

In the remote prescientific ages, when hygienic sanitation was still nonexistent, when physiological and pharmaceutical chemistry had still many centuries to wait before birth, and when man's murderous enmity to man was more (superficially) evident than in our present generation, disease and injury were treated by an unlimited variety of the respective products of the "three kingdoms of nature." Every remarkable mineral product was accorded a place in the therapeutic armamentarium; and, in accordance with its unequalled pecularities, the loadstone found special recognition. Harvey arranges the clinical capabilities thereof in the third compartment of his quatenary classification of its properties:

They are either mechanical, nautical, medicinal, or fabulous. Its mechanical properties of attracting iron: nautical, of inclining or moving towards the north pole, and

thereby of directing mariners in steering their course, of which more anon; medicinal, of adstriction and stenching blood. Ætius, lib, iii, tetrabl. cap. 25, gives us this account of its medicinal vertues: The Magnete or Herculean stone hath the same vertues which a blood stone hath: They say that it doth asswage the pains of the gout in the feet and in the wrist, if held in the hand. This is fabulous, but if applied being mixt with other ingredients in a plaster, it doth really give ease in some kinds of gouts. Serap. lib. de Simpl. part. 2, cap. 384, commends the magnete for curing wounds befaln by a venomous weapon; it is to be powdered and mixt with other oyntments and applied to take a dose of it internally until the venom is purged away by stool. Parey, lib. vii, Chir., cap. 15, attributes a very memorable cure of a bursted belly to it. Fabr. Hildan, Cent. 5. Observ. Chir. 21. Obs., rehearses a famous cure luckily done by it by the advice of his wife (at a dead lift, I suppose) upon a merchant, who was tormented with a miserable pain in one of his eyes caused by a little piece of steel that was accidentally pierced into it. All kind of anodynes were applied, but to purpose, at last the loadstone was thought upon, which he caused to be held near to the eye, whereby it was soon

In contrast to the remarkable reputation of the loadstone as an external application is the comparatively unfavorable estimate of its functional powers when administered internally. The great medical lexicographer, Dr. James, of "fever pow-der" fame, tells us (1745) that: "The loadstone is found in many parts of Europe, and for the most part in iron mines; but the best are those which come from the East Indies and Ethiopia. It is, undoubtedly, a kind of iron ore; and, in some places in Germany, they actually extract the iron it contains: When exposed in the focus of a great burning glass, it likewise manifestly discovers iron. . . . The loadstone is not used inwardly in physic, though Galen says it has the same virtues as the bloodstone; and, also, mentions its purgative virtue, and recommends it, on that account, in dropsies. Dioscorides proposes that it be given in the quantity of three oboli, to evacuate gross melancholy humours. Some think it possessed of a deleterious quality, which is denied by others; but I imagine the poisonous quality is to be understood of that kind of magnes mentioned by Theophrastus, which I take to be a kind of native litharge.

In commenting on the fourth class of the properties of this mineral, Gideon Harvey proceeds to state that:

The fabulous properties of this stone are of losing its attractive virtue by the apposition of a diamond; of curing wounds at a distance, for which purpose it is added to Bombasts sympathetical oyntment; and of preserving youth, for which end they say the King of Zeylan causes his victuals to be dressed in magnete dishes.

And James, already quoted, observes in the same connection:

The true loadstone, externally used, is drying, astringent, and consolidating. It is an ingredient in the emplastrum manus dei, emplastrum divinum, emplastrum nigrum, and emplastrum stypticum of Charas. Geoffroy.

It is of an astringent quality, and stops bleeding; being burnt, it expels gross and atrabilious humours, but it is seldom used. Schroder. It is prescribed in hernias. Hoffman. Paracelsus makes it an ingredient in a plaister prepared, not only for extracting the head of an arrow from the human body, but all manner of dirt and filth whatever. Dale.

The unique properties of loadstone had, in accordance with the promptings of some of the fundamental instincts of human nature, been a source of

continuous stimulation to experiment, and inquiry, and hypothesis, ever since its first discovery. Many of the resulting facts and surmises were critically discussed by the accomplished author of the *Religio Medici*. That enterprising crusader against popular error tells us that:

We conceive the earth to be a magneticall body. A magnetical body, we term not only that which hath a power attractive, but that which seated in a convenient medium naturally disposeth it self to one invariable and fixed situation. And such a magnetical vertue we conceive to be in the globe of the earth; whereby as unto its naturall points and proper terms it disposeth it self unto the poles, being so framed, constituted and ordered unto these points, that those parts which are now at the poles, would not naturally abide under the æquator, nor Green-land remain in the place of Magellanica; and if the whole earth were violently removed, yet would it not forgoe its primitive points, nor pitch in the east or west, but return unto its polary position again. This is probably that foundation the wisdome of the Creator hath laid unto the earth, and in this sense we may more nearly apprehend, and sensibly make out the expressions of Holy Scripture, as that of Ps. 93:I. Firmavit orbem terræ qui non commovebitur, he hath made the round world so sure that it cannot be moved: as when it is said by Job, Extendit aquilonem super vacuo, &c. Hee stretcheth forth the north upon the empty place, and hangeth the earth upon nothing. And this is the most probable answer unto that great question, Job 38, where-upon are the foundations of the earth fastened, or who laid the corner stone thereof? Had they been acquainted with this principle, Anaxagoras, Socrates, and Democritus had better made out the ground of this stability: Xenophanes had not been faine to say it had no bottome, and Thales Milesius to make it swim in water.

After discussion of its cosmic polarity, Browne refers in some very interesting paragraphs to the characteristic power of attraction displayed by the loadstone, and indicates the fallacies of some of the popular "tenents" to which such peculiarities had given rise:

"For perceiving its secret power to draw unto it selfe magneticall bodies, men have invented a new attraction to draw out the dolor and paine of any part. And from such grounds it surely became a philter, and was conceived a medicine of some venereall attraction, and therefore upon this stone they graved the Image of Venus according unto that of Claudian, Venerem magnetica gemma figurat. Hither must wee also referre what is delivered concerning its power to draw out of the body bullets and heads of arrows, and for the like intention is mixed up in plaisters; which course although as vaine and ineffectuall it be rejected by many good Authors, yet it is not me thinks so readily to bee denyed, nor the practice of many ages and physitians which have thus compounded plaisters, thus suddenly to be condemed. "Here he refers approved." denly to be condemned, . Here he refers, approvingly, to the reported "cure also of heurnias or ruptures in (i. e., Ambroise Paré); and to "the methods also of curation lately delivered by Daniel Beckherus, and approved by the professors of Leyden in the tract de Cultivoro Prussiaco, 1636, that is of a young man of Sprucéland that casually swallowed downe a knife about ten inches long, which was cut out of his stomach and the wound healed up. In which cure to attract the knife to a convenient situation, there was applied a plaister made up with the pow-der of loadstone." In his comment, he does not neglect to point out that Libavius, one of the foremost chemical experts of his generation, had been led to "condemne, as vaine and altogether unusefull" this use of magnetic plasters; and also that such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus (the recognized for the such was the teaching of Gillbertus). nized father of magnetic science), and so "lately Swick-ardus in his Ars magnetica." Here our author proves that he had, himself, tested the respective values of the contra-dictory assertions: "Their reason is, because a loadstone in powder hath no attractive power; for in that forme it omits his polary respects, and looseth those parts which are the rule of its attraction: wherein to speake compendiously, if experiment hath not deceived us, we first affirme, that a loadstone in powder omits not all attraction. As we have made triall in the emplastrum de minio, with

halfe an ounce of the masse, mixing a dram of loadstone, for applying the magdaleon or roale unto the needle it would both stir and attract it; not equally in all parts, but more vigorously in some, according unto the mine of the stone more plentifully dispersed in the masse." And his final summing up on this question is: "Now though we affirme not the plaisters wholly ineffectual, yet shall we not omit two cautions in their use, that therein the stone be not too subtily powdered; for it will better manifest its attraction in a more sensible dimension; that where is desired a an a more sensine dimension, that whether it were not better to relinquish the powdered plaisters, and to apply an entyre loadstone unto the part: And though the other be not wholly ineffectuall, whether this way be not more powerfull, and so might have been in the cure of the young man delivered by Beckerus.

But it is from the invention of "a new attraction," which was used by popular imagination to decorate the natural one, that the same author would account for "what is let fall by Ætius, that a loadstone held in the hand of one that is podagricall doth either cure or give great ease in the gout. Or what Marcellus Empericus affirmeth, that as an amulet it also cureth the head-ach, which are but additions unto its proper nature, and hopefull enlargements of its allowed attraction." And even more emphatically does our author reject the very mediæval opinion "delivered by some that a loadstone preserved in the salt of a Remora, acquires a power to attract gold out of the deepest wells. Certainly a studied absurdity, . . ." Also the "shrewd quality" which "Dioscorides puts upon it" in his statement that he "discovers the incontinence of a wife by placing the Loadstone under her pillow, for then shee will not be able to remaine in bed with her husband"; the "Lithomancy or divination from this stone, whereby . . . Helenus the Prophet fore-told the destruction of Troy"; the anæsthetic virtue of "the loadstone of Laurentius Guascus the Physitian . . . wherewith as Cardane delivereth, whatsoever needles or bodies were touched, the wounds and punctures made thereby, were never felt at all"; and the much less fascinating quality (also attributed to it by Dioscorides) which made it so useful to burglars: "theeves, saithe he, having a designe upon a house, doe make fire at the foure corners thereof, and cast therein the fragments of Loadstone, whence ariseth a fume that so disturbeth the inhabitants, that they forsake the house and leave it to the spoyl of the robbers.'

But a sadly-yet it may well be added, hopefully -instructive lesson in the vanity of scientific prophesy is afforded by Browne's rather confident opinion-and prediction-regarding the curious speculative anticipation of a magnetic telegraph, to which I have also shown a reference, in a quotation from Gideon Harvey. The learned and devout author of the Religio Medici discusses this subject with an evidently keen interest; and his remarks can, I venture to think, hardly fail to arrest the attention of the earnest student of human opinion and of scientific progress-even in our enlightened

twentieth century.

The conceit is excellent, and if the effect would follow somewhat divine, whereby we might communicate like spirits, and conferre on earth with Menippus in the Moone; which is pretended from the sympathy of two needles touched with the same loadstone, and placed in the center of two Abccedary circles, or rings with letters described round about them; one friend keeping one, and another the other, and agreeing upon an houre wherein they will

communicate. For then, saith tradition, at what distance of place soever, when one needle shall be removed unto any the same. But herein I must confesse my experience can finde no truth; for having expressly framed two circles of wood, and according to the number of the Latine letters divided each into twenty three parts, placing therein two stiles or needles composed of the same steele, touched with the same Loadstone, and at the same point: yet of these two, whensoever I removed the one, although but at the distance of halfe a spanne, the other would stand like Her-cules pillars, and if the earth stand still, have surely no motion at all. Now as it is not possible that any body should have no boundaryes, or as we terme it Sphere of its activity, so is it improbable it should effect that at distance, which nearer hand it cannot at all performe.

Againe, the conceit is ill contrived, and one effect inferred, Againe, the concerts in Contrived, and one effect interred, whereas indeed the contrary will ensue. For if the removing of one of the needles from A to B should have any action or influence on the other, it would not intice it from A to B, but repel it from A to Z: for needles excited by the same point of the stone doe not attract, but avoyd each other, even as these also do, when their invigorated

extreams approach unto one another

Lastly, were this conceit assuredly true, yet were it not a conclusion at every distance to be tryed by every head: yet being no ordinary or Almanack businesse, but a prob-Jeme Mathematicall, to finde out the difference of houres in different places; nor doe the wisest exactly satisfie themselves in all. For the houres of severall places anticipate each other, acording unto their longitudes, which are not exactly satisfied to the control of the actly discovered of every place, and therefore the triall hereof at a considerable intervall, is best performed at the distance of the Antæci; that is, such habitations as have the same meridian and equall parallel, on different sides of the equator; or more plainly have the same longitude, and the same latitude unto the south, which wee have in the north. For unto such situations it is noone and midnight at the very same time.

To the statement of such objections logically propounded, as they undoubtedly are, in the light of the fullest scientific attainment of that period, he appends a further illustrative one derived from associations of a directly professional nature—and couched in a tone of slyly sarcastic humor, while displaying a rare mastery of the varied associations of the science of physical experiment with that of surgical practice.

And therefore the Sympathie of these needles is much of the same mould, with that intelligence which is pretended from the flesh of one body transmuted by incision into another. For if the Arte of Taliacotius de Curlorum Chyrurgia per incisionem, a permutation of flesh or transmutation be made from one mans body into another, as if a piece of flesh be exchanged from the biciptall muscle of either parties arme, and about them both, an Alphabet circumscribed upon a time appointed as some conceptions affirme, they may communicate at what distance soever. For if ntme, they may communicate at what distance soever. For it the one shall prick himself in A, the other at the same time will have a sense thereof in the same part; and upon inspection of his arme, perceive what letters the other points out in his owne; which is a way of intelligence very strange, and would require the Arte of Pythagoras; who could read a reverse in the Moone

Those readers who are familiar, as all should be, with the works of the contemporary author of Hudibras, will at once recall the lines which contribute their testimony to the vividness of the impression with which the practice of the famous Italian apostle of rhinoplastic surgery had titillated the imaginations of both literary and medical men in that generation:

> So learned Tatiacotius, from The brawny part of porter's bum, Cut supplemental noses, which Would last as long as parent breech; But when the date of Nock was out; Off dropp't the sympathetic snout.

The idea of telepathic sympathy (and of antipathy) was very much in the air, indeed, in that generation, as in some preceding ones; and may perhaps be regarded as one of the symptoms of the hankering after the mysterious, the unknowable, and the unattainable, which has accompanied humanity in all its wanderings since the original exile from the Garden of Eden. Dr. Fludd (Robertus de Fluctibus) refers to the case of an Italian nobleman, of whose nasal appendage the major portion had been sliced off in a duel, and who induced a slave, by promise of freedom and a reward, to permit the formation of a wound on his arm, to the margins of which the stump of the amputated nose was secured by stitches. When union had taken place, a nose shaped piece was cut out from the flesh (and investing skin) of the arm, and duly dressed. The operation was perfectly successful. The emancipated slave went to Naples, and died there, and at the moment of his death gangrene of the transplanted portion of the nose set in. The patient was then advised to have a piece of his own arm utilized. Encouraged by the result of the previous operation, he agreed, and the result was a lifelong success. The operation described and figured by Taliacotius was of the latter form.

On the subject of the therapeutical properties of the loadstone—both for internal administration and external application—and some others specially correlated thereunto, Browne expresses his opinions more explicitly and precisely than he usually does on facts or questions that are chiefly or wholly associated with professional matters—on which he is, as a rule, peculiarly reserved. With regard to its immediate effect on the alimentary canal we are

informed that:

Unto the ferreous and mineral quality pertaineth what Dioscorides, an ancient writer and soldier under Anthony and Cleopatra, affirmeth, that halfe a dram of loadstone, given with honey and water, proves a purgative medicine, and evacuateth grosse humors; but this is a quality of great uncertainty, for omitting the vehicle of water and honey, which is of a laxative power itselfe, the powder of some loadstones in this dose doth rather constipate and binde, than purge and loosen the belly. And if sometimes it cause any laxity it is probably in the same way with iron and steele unprepared, which will disturbe some bodies, and worke by purge and vomit. And therefore what it delivered in a book ascribed unto Galen that it is a good medicine in dropsies, and evacuates the waters of persons so affected: It may I confesse by siccity and astriction afford a confirmation unto parts relaxed, and such as the hydropically disposed, and by these qualities it may be useful in hernias or ruptures, and for these it is commended by Ætius, Ægineta and Oribascus, who only affirme that it contains the virtue of Hæmatiteus, and being burnt was sometimes vended for it.

In curious contrast to the anæsthetic properties ascribed to at least one specimen of loadstone by the mystically medical and weird visionary, Jerome Cardan, we find that an opinion of local malignancy was "delivered by some, that wounds which are made with weapons excited by the loadstone contract the malignity and become of more difficult cure; which, nevertheless, is not to be found in the incisions of chyrurgions with knives and lances touched, which leave no such effect behind them." It, would almost seem that the original exponent of this opinion had been inspired by a perverse ambition of furnishing an opposite pole to his magnet—in the special meridian of his therapeutic domain!

And a corresponding contradictory criticism is offered on the strange monstrosity of physical opinion which endowed this mineral with toxic proper-"Hitherto must we also referre that affirmative which sayes the loadstone is poyson, and therefore in the list of poysons we finde it in many authors; but this our experience cannot confirme. and the practice of the King of Zeilan clearly contradicteth, who as Garcias ab Horto, Physitian unto the Spanish viceroy delivereth, hath all his meat served up in dishes of loadstone, and conceives he preserveth the vigor of youth." This tendency of humanity to attribute supplemental and auxiliary virtues to mysterious substances, especially those of remote and unknown origin, was also illustrated by the crediting of corresponding preservative powers to China dishes when these were first imported into the Occident.

Whether observation of the unique peculiarities of this variety of iron ore was the original directive agency in leading to the discovery and metallurgy of elemental iron is a question which we cannot, of course, hope to be able to answer satisfactorily, either now or at any future date. Nevertheless. the transition of the point of view from mineral to element affords an opportunity for contemplative digression which presents many points and aspects of peculiar interest in the present state of physical and of philosophical science. The philosophical historians of the gradual evolution of human opinion in the contemplation of matters physical have pointed out the fewness and unchangeableness of the "species of objects" in the heavens above, of the existence of which the evidence of human sense was unable to testify. The sun, the moon, planets, and fixed stars became symbolic of unchanging stability, in appearance and periodic movement. The appearances of the meteors of the air, with its ever changing clouds and its sudden and violent storms, were diversified to an incalculable degree. creatures of the waters, and those of the earth, on and beneath its surface; its plants and its animals, its fossils and its minerals, were still more variously and more intricately diversified. Accordingly:

If we regard the different manners of their production, their mutual influence in altering, destroying, or supporting one another, the orders of their succession seem to admit of an almost infinite variety. If the imagination, therefore, when it considered the appearances in the heavens was often perplexed and driven out of its nautral career, it would be much more exposed to the same embarrassment, when it directed its attention to the objects which the Earth presented to it, and when it endeavored to trace their progress and successive revolutions. To introduce order and coherence into the mind's conception of this seeming chaos of dissimilar and disjointed appearances, it was necessary to deduce all their qualities, operations, and laws of succession, from those of some particular things with which it was perfectly acquainted and familiar, and along with which its imagination could glide smoothly and easily and without interruption. But as we would in vain attempt to deduce the heat of a stove from that of an open chimney, unless we could show that the same fire which was exposed in the one lay concealed in the other, so it was impossible to deduce the qualities and laws of succession observed in the more uncommon appearances of Nature from those of such as were more familiar, if those customary objects were not supposed, however disguised in their appearance, to enter into the composition of those rarer and more singular phenomena. To render, therefore, this lower part of the great theatre of Nature a coherent spectacle to the imagination, it became necessary to suppose, first, that all the strange objects of which it consisted were made up

out of a few, with which the mind was extremely familiar: and secondly, That all their qualities, operations, and rules of succession, were no more than different diversifications of those to which it had long been accus-

tomed, in these primary and elementary objects.

Of all the bodies of which these inferior parts of the universe seem to be composed, those with which we are most familiar are the Earth, which we tread upon; the Water, which we every day use; the Air, which we constantly breathe; and the Fire, whose benign influence is not only required for preparing the common necessaries of life, but for the continual support of that vital principle which actuates both plants and animals. These therefore were by Empedocles, and the other philosophers of the Italian school, supposed to be the elements, out of which, at least, all the inferior parts of Nature were composed. The familiarity of those bodies to the mind, naturally disposed it to look for some resemblance to them in whatever else was presented to its consideration. . . The heat, observed m both plants and animals, seemed to demonstrate, that Fire made a part of their composition. Air was not less necessary for the subsistence of both, and seemed, too, to enter into the fabric of animals by respiration, and into that of plants by some other means. The juices which circulated through them showed how much of their texture was owing to water. And their resolution into Earth by putrefaction discovered that this element had not been left out in their original formation.

Such was the original genesis of the theory of elements, according to the above well informed sketch drawn by a writer of the eighteenth century, who thus proceeds to a consideration of their leading attributes:

The qualities, too, by which we are chiefly accustomed to characterize and distinguish natural bodies, are all of them found, in the highest degree in those Four Elements: The great divisions of the objects, near to the surface of the Earth, are those into hot and cold, moist and dry, light and heavy. These are the most remarkable properties of bodies; and it is upon them that many of their other most sensible qualities and powers seem to depend. Of these, heat and cold were, naturally enough, regarded by those first inquirers into nature, as the active; moisture and dryness as the passive, qualities of matter. It was the temperature of heat and cold which seemed to occasion the growth and dissolution of plants and animals; as appeared evidently from the effects of the change of the seasons upon both. A proper degree of moisture and dryness was not less necessary for these purposes; as was evident from the different effects and productions of wet and dry seasons and soils. It was the heat and cold, however, which actuated and determined these two otherwise inert qualities of things, to a state either of rest or motion. Gravity and levity were regarded as the two principles of motion, which directed all sublunary things to their proper place; and all these six qualities, taken together, were, upon such an inattentive view of nature, as must be expected in the beginnings of philosophy, readily enough apprehended to be capable of connecting together the most remarkable revolutions, which occur in these inferior parts of the universe.

The influence of these properties was: "Each of those four elements, had, in the system of the universe, a place which was peculiarly allotted to it, and to which it naturally tended. Earth and water rolled down to the centre; the air spread itself above them; while the fire soared aloft, either to the celestial region or that which was immediately below it. When each of those simple bodies had thus obtained its proper sphere, there was nothing in the nature of any one of them to make it pass into the place of the other, to make the fire descend into the air, the air into the water, or the water into the earth; or, on the contrary, to bring up the earth into the place of the water, the water into that of the air, or the air into that of the fire. All sublunary things, therefore, if left to themselves, would have remained in an eternal repose. The revolution of the heavens, those of the sun, moon, and five planets, by producing the vicissitudes of day and night, and of the seasons, prevented this torpor and inactivity from reigning through the inferior parts of nature; inflamed by the rapidity of their circumvolutions, the element of fire was liberated, and forced violently downwards into the air, into the water, into the earth; and thereby produced those mixtures of the different elements which kept up the motion and circulation of the lower parts of nature; occasioned sometimes the entire transmutation of one element into another, and sometimes the production of forms and species different from them all; and in which, though the qualities of them all might be found, they were so altered and attempered by the mixture as to be scarcely distinguishable." Such were the ideas of universe and of element, of matter and of spirit, in those days of self torturing introspective effort towards the attainment of truth.

A really curious fact with regard to iron is that the therapeutic history of this metallic element seems to reach almost as far back into the shades of remote antiquity as does that of its military and domestic uses. Surviving testimony goes to show that the Greeks employed it at the siege of Troy; not only in the construction of weapons and machines of war, but therapeutically—as a local application to wounds, on account of its known healing (hæmostatic and astringent?) properties. language of the elder Pliny-as quaintly Englished by Philemon Holland, Doctor of Physicke-we are told that: "The very rust of yron also is counted medicinable; for so Achilles is said to have treated Telephus; but whether the head of his speare were iron or brasse, of which he used the rust, I doe not certainly know. Certes, he is paynted thus: With his sword scraping and shaking off the rust into the wound." Modern readers will, I dare say, incline -preferringly-to the belief that the said rust was

More remarkable still is the fact that the tonic properties of iron were recognized in Greece in the remote ages of its fabulous antiquity. We learn from Apollodorus that Melampus used it—successfully, too—to restore the failing virility of Iphikles: "he is said to have directed *I*. to take the Rust of a Knife, and drink it in Wine, ten days together, in order to procure him Children." (James.)

The opening sentences of Pliny's account of iron are, as very usual with him, mainly philosophic:

Yron, a mettal which we may well say is both the best and the worst implement vsed now in the world; for with the helpe of yron we break up-and ear the ground, we plant and plot our groues, we set our hortyards and range our fruitful trees in rewes; we prune our vines and by outting off the superfluous branches and dead wood, we make them euery yere to look fresh and yong againe; by meanes of yron and steele we build houses, hew quarries, and cut in stone, yea, and in one word, wee vse it to all other necessary vses of this life. Contrariwise, the same yron serueth for wars, murders, and robberies, not onely to offend and strike therewith in hand, but also to reach and kill afarre off, with diures sorts of darts and shot; one while discharged and sent out of engines, another while lanced and flung by the force of the arme; yea, and sometime let flie with wings: and this I take to be the wickedest intention that euer was deuised by the head of man; for to the end that death may speed away the faster to a man, and surprise him more suddenly, we make it to flie as a bird in the aire, and to the arrow headed at the one end

with deadly yron, we set feathers at the other: whereby it to be imputed to the nature of it, but to the vnhappy wit

Such has been the reflection of every philanthropic philosopher, down through all the centuries of recorded time, whenever his thoughts were directed toward a solution of the problematic query: "Why man was made to mourn?"!

And the same gossipy, and apparently most credulous, "authority" on the therapeutic science and practice of those classical (and preclassical) ages gives us, as usual, a very clearly sketched and detailed picture of the collective knowledge, or opinion, of his own (and earlier) times, in connection with matters "martial":

As touching the vertues thereof, it is clensing, exiccatiue, and astringent; it recouereth the haire in places despoiled thereof, if they be annointed therewith in the forme of a liminent; being reduced into a salue with wax and oile of Myrtles incorporate together, many vse it for roughnesse about the eie-lids; the pimples also breaking forth all ouer the body. For shingles and S. Antonies fire, it is singular good to apply it in an vnguent with vinegar; likewise it killeth scabs, and healeth whitflawes of the fingers, and the excrescence or turning vp of the flesh about the roots of the nails, if linnen rags wet therein be applied conveniently. The same conveyed vp in wooll after the manner of a pessary into the natural parts of women, staieth the immoderat flux both of whites and reds. The rust of yron tempered in wine, and wrought together with Myrrhe, is good for a greene wound: put thereto vinegar, and then it helpeth the piles and swelling bigges of the fundament. A liniment made with it, mitigateth the pain of the gout.

As touching the skales of yron that flie from the edge or point of any weapon wrought in the smiths forge: they serue in the same cases that the rust doth, and haue the like effects, saue only this, that they haue greater acri-monie, and work more eagerly: in which regard they are emploied about the repressing of the flux that falleth into watering eies. But marke this one thing: Yron being that which woundeth most and sheddeth bloud, yet the skales that come from it, stanch the same: a property they haue besides to stop the flux in women: and being applied to the region of the spleene, they do open the obstructions thereof, and ease other infirmities incident thereto: the running hæmorrhoids they represse, and such vicers as are given to spread farther and corrode as they go. Reduced into a fine powder and gently strewed vpon the eye-lids, they are good for the accidents thereto belonging. But the principal vse of them, and for which they are most commended, is in a certain liquid plaster called Hygremplastrum; which serueth to mundifie wounds, vicers, and fistulæs; to eat away all callosities, and to incarnate and ingender new flesh about bones that are perished. And this is the receit of that composition: Take of the scouring Tuckers earth the weight of two oboli, of brasse six drams, of the skales of yron as much, and no lesse of wax, incorporat all these according to the art in one sextar of oile. But in case there be need to mundifie any sores, or to incarnat, there would be put thereto some plain cerot besides.

The above extract, from the pages of the earliest encyclopædia of Materia Medica known to Western science, clearly proves that the clinical properties of martial preparations which have stood the test of time are those which were known in the prescientific ages; and were, accordingly, the exclusive revelations of methods wholly empirical. In fact, almost the only great central fact revealed by modern science in this connection is that iron is the one heavy metal which our food must contain-the human animated machine absolutely requiring its presence; in its original construction, and throughout every stage of its continuous repair. Of course, we have been treated to an endless series of statements regarding absorption and elimination, in approximately parallel columns of contradictory affirmations: intestinal absorption a fact and a fable; urea increased and decreased, etc., etc.; but our most important clinical facts are all empirical!

And another valuable therapeutic item is offered for the reader's instruction in a later paragraph:

Gads of steele or other yron red hot quenched in water, so long vntil the same water be hot, causeth it to be a wholesome drinke in many diseases, but principally in the

Dr. James (who prepared the famous "fever powder") tells his readers how: "Dioscorides attributes to it an astringent virtue, and recommends it in uterine hæmorrhages. He, likewise, orders wine, or water, in which a red hot iron has been quenched, in the cœliac passion, lientery, and dysentery, and for restoring weak stomachs. Physicians now acknowledge a twofold virtue in iron, one aperient, the other astringent; for it is observed to cure a suppression of the menses, to open obstructions of the liver, spleen and other viscera, to stop hæmorrhages and diarrhœas, and to strengthen the relaxed fibres of the intestines. On these accounts it is reckoned the grand specific in hypochondriacal affections, and all kinds of chloroses. Some attribute an aperient virtue to some preparations of iron, and an astringent virtue to others; but the truth is, all these preparations are both astringent and aperient, though not in the same degree.

As compared with his therapeutics, Pliny's views on the uses of iron in surgery and demonology are somewhat more erratic. In the classic ages of Pagan antiquity, the physical agents which were most efficacious in their salutary effects on the human body were those which were supposed to be possessed of concurrent mystical or weirdly occult properties as well. One feature led to the recognition of the other; probably no one knew which had been first discovered. Our encyclopædic authority

tells us that:

As touching the vse of yron and steele, in Physicke it serueth otherwise than for to launce, cut, and dismember withall: for take a knife or dagger and make an imaginarie circle two or three times with the point thereof, vpon a young child, or an elder body, and then goe around withall all about the party as often, it is a singular preservative against all poisons, sorceries or inchantments. Also to take any yron naile out of the coffin or sepulchre wherein man or woman lieth buried, and to sticke the same fast to the lintle or side post of a dore, leading either into the house or bed-chamber where any doth lie who is haunted with spirits in the night, hee or shee shall be delivered and secured from such phantasticall illusions. Moreouer, it is said, that if one be lightly pricked with the point of a sword or dagger which hath beene the death of a man, it is an excellent remedy against the pains of sides or brest, which come with sudden pricks and stitches. An actuall cauterie of yron, red hot, cureth many diseases, and especially the biting of a mad dog; in which case it so effectuall, that if the poison inflicted by that wound, haue preuailed so far, that the patient be fallen into a Hydrophobie thereby, and cannot abide drinke or water, let the sore be seared therewith, the party shall find help presently.

The possession of uncanny and supernatural powers was very confidently attributed to iron in the remote ages of classic antiquity, as the statement of Pliny contained in the above quotation conclusively proves. And this interesting fact furnishes a "quaint and curious" item of collateral testimony in favor of the common kinship and probable original unity of source and development of the primitive notions of untutored humanity regarding such subjects. In the more remote districts of the west and south of Ireland, corresponding faith in the powers and virtues of "the blessed iron" was universally diffused among the peasantry -at least before the days of the enlightenment of "intermediate education." The benighted traveler who bore in his hand an iron or steel weapon could always pass, with safety, the haunted cross road or the "gentle" rath. He might even venture with impunity to intersect the pathway of transit of the local "gentry" in the course of their midnight change of residence, which took place annually at Hallowe'en-with the most unfailing chronometric regularity. Without such safeguard, such intersection never failed to prove a most "regrettable incident." The midnight wanderer was "taken away" by the moving band of the "good people," and a pining changeling was left instead. The latter was a dangerous, as well as unholy, inmate of the hut to which it was conveyed; and could be safely and effectively got rid of only by "taking it on the shovel and pitching it out of the door." The shovel blade being always formed of the "blessed" metal, the diabolical individual could not attempt to reenter the door; and so was obliged to vanish-and always, in doing so, displayed his impotent vindictiveness by "going off in flames of fire" and leaving "a strong smell of brimstone" behind! Lucifer himself always winced and retired when opposed by an iron weapon. Millions of-very literally-illiterate persons, who had never even heard of the name of Shakespeare, knew that "no fairy takes, nor witch hath power to charm" the happy and privileged individual who is protected by a metal "so gracious and so hallowed."

All readers are, of course, aware that the "theory and practice" of medicine, and the "science and art" of surgery were peculiarly unprogressive during the series of centuries so usually referred to as "the dark ages." The Arab physicians were the principal, almost the sole recognized, teachers; and they altered but few indeed of the doctorial dicta of Hippocrates, as expanded and transmitted to posterity in the comments and interpretations of his philosophic disciple, Galen. In medicine (as in philosophy and theology) "authority" reigned supreme. But while the absolute truths of wisdom, divine and human, were justly and wisely regarded and treated as unchanging and unalterable, the infancy of the healing art was long deprived of its birthright of healthy growth and freedom of movement; an approximately successful effort was made to retain it in its original Grecian cradle, and to limit the dangers to itself and to others which might result from unguided excursions, by keeping it carefully wrapped up in its earliest suit of swaddling clothes. The influence of "authority" was paramount in almost every department of human knowledge, throughout the greater part of that strange period of the progress (or stagnation) of the intellectual evolution and social civilization of Western Europe-to a degree which would be pretty hard for the most imaginative of us to realize in this twentieth century of universally diffused education, political emancipation, and legal equality of individual rights. The teaching of medicine

was no exception to this universal rule in the communication of knowledge, and the control of opinions-and the practice thereon based. Accordingly, there was no legitimate scope for the expansion of scientific theory in this department. Such development was doomed to await the explosive intellectual upheaval of the Renaissance; and the manifold postsequent political, social, ecclesiastical and educational phenomena and associated events. And down to that period the recognized teachers of medicine-both in theory and practice-still clung closely to the classical authorities whose science and traditional lore are still most fully represented in the vast thesauri of the elder Pliny and of Claudius Galen, respectively. And it is interesting to note here how the principal items of the therapeutic reputation of the first metal utilized in clinical practice retained their vitality through the seismic shocks of the Renaissance. Its uses were fully recognized by Paracelsus himself; and the comic element seems to obtrude itself in the coinage of the barbaric term Colcothar by the "Luther of Medicine" to connote the product of calcination of green vitriol (to which was added a quantum of common salt, and one of myrrh), that he used in the treatment of dropsies—thereby imitating pretty closely the practice of the great physician of Pergamum, while publicly denouncing his "authority" with the most foul mouthed scurrility.

(To be concluded.

REPORT OF 422 CASES OF A GENERAL SUR-GICAL NATURE FROM THE SURGICAL SERVICE OF FORDHAM HOSPITAL.

With Remarks.

By Alexander Nicoll, M. D., New York,

Associate Professor of Surgery, Fordham University, School of Medicine; Visiting Surgeon to Fordham Hospital; Chief of the Surgical Clinic, St. Vincent's Hospital.

During the past summer, in my service at Fordham Hospital, over four hundred cases of a general surgical nature came under my care. A consideration of this group of cases is interesting per se, and because it suggests certain points regarding such a service that, in themselves, are of special importance to the men who are actively engaged in hospital work. The method of reporting a series of cases of this nature, merely stating the number of cases treated, the number of deaths, and the number of cases cured, improved, or unimproved, without giving a thorough and painstaking tabulated list showing the nature of each case upon which the result was obtained, has always seemed to me to be an unsatisfactory one. Occasionally an exceptionally high death rate dwindles to a remarkably low one when the character of the cases is taken into consideration. On the other hand, to report a large series of cases with an unusually low death rate, without indicating the character of the individual cases, smacks too much of the man who "has never had a death following an operation for appendicitis." This gentleman is not infrequently brought to our notice by the laity, and is the cause of much mental weeping and wailing and impotent gnashing of teeth among men who know him for what he is, either a practitioner who, shirking his

The total number of cases treated was 422. The total number of deaths was 39. The total mortality

was 9.2 per cent.

Of the fatal cases twenty-four patients died within twenty-four hours of their admission to the hospital, and can therefore be reasonably considered to have had little chance of recovery. This class includes the cases which were fatally burnt, and those cases which were admitted hopelessly injured or with advanced general peritonitis. Excluding this number the death rate was 3.5 per cent. This method seems to me to be a fair way of arriving at what may be considered the legitimate mortality of a service composed of cases of a mixed surgical nature, and into which the element of trauma enters to any appreciable degree. Trauma was the causative factor in nineteen of the fatal cases, or fortynine per cent. of the total number.

Of course figures do not lie but they are capable, nevertheless, of a certain amount of trickery and

malicious deception. The legitimate death rate of a hospital service depends upon so many factors that it is impossible to fix any hard and fast rule by which to figure Putting aside the question of the amount and character of the skill and knowledge possessed by the visiting surgeon, and the alertness of the house surgeon, we still have a number of very important factors, all of which have a decided influence upon this matter of legitimate mortality: The location of the hospital; the extent and climatic conditions of its district; the amount of traumatic surgery which may be expected from near by factories and railroad yards; the amount of special surgery contributed by settlements of people, both for eign born and native, who have lost faith in the soft answer that turneth away wrath, and who have earned by bitter experience that to turn the other

check too often results in the loss of the entire head

- hence the bullet and stab wounds. All these fac-

tors have their bearing upon the mortality of a service. Finally the *entente cordiale* existing between

the members of the medical board of the hospital on the one hand, and the private practitioners of the district in which the hospital is located on the other, will do more, in my opinion, to influence the mortality of any hospital than any other factor mentioned. I have found, statements concerning the growing commercial spirit among medical men to the contrary notwithstanding, that the great majority of the patients admitted to the charity wards of Fordham Hospial for acute illness of any sort were seen, previous to admission, by some man in private practice who, in the course of his ordinary work, had given his time and attention freely and cheerfully. These men have a powerful influence upon the course of cases which eventually come into the charity wards of hospitals. The general practitioner can, by his advice to the poor man stricken with appendicitis, for example, hasten the patient's entrance to the hospital and thus insure for him an early operation while he is still in good condition; or he can, by delay, prolong the preoperative stage of a severe peritoneal infection to such an extent that the patient finally reaches the surgeon's hands in a condition that practically precludes the possibility of recovery. Unfortunately the case which is moribund upon admission is still of woefully common occurrence in all our hospitals. It has always been my rule to operate on all cases which by their symptoms indicate a fatal termination under any other form of treatment no matter how hopeless the outlook appears to be, unless the patient is actually in extremis

One point which struck me most forcibly was observed in connection with the cases of acute peritoneal infection. In several cases in which obstipation was a persistent factor, due either to mechanical obstruction or to the severity of the infection, the appearance of the intestine, particularly the small intestine, was most suggestive. At operation this viscus was, as a rule, enormously dis-tended, deep red in color, "meaty" in appearance, and had lost its tone completely. It had a peculiar "porous" look which seemed to openly invite invasion from the infecting organism. While this condition was undoubtedly due in part to the actual infection and septic sympathetic paralysis, I am convinced that another factor played a by no means unimportant part in its production. I refer to the injudicious use of cathartics. In each of the cases in which the condition which I have mentioned was encountered there was a definite history of the abuse of purgatives previous to the admission of the patient to the hospital. I believe that the overenthusiastic exhibition of this class of drugs reduces the intestinal coats to a condition of such muscular and nervous exhaustion that not only is the power of immediate resistance to infection markedly lowered, but their power of muscular recovery is diminished to such an extent that postoperative meteorism, the bête noir of the abdominal surgeon, is rendered practically certain. Another point on this question is this—the time of operation is noticeably lengthened owing to the great difficulty of working in an abdominal cavity filled with distended intestines, and the shock of the anæsthetic, and that due to the occasional necessity for puncture of the distended gut and the unavoidable rough handling of the intestines, is markedly and unnecessarily increased. Indeed, I feel that too much care cannot be exercised in the use of purgatives in dealing with obstipation of any sort when there is the slightest amount of abdominal tenderness or rigidity.

Perhaps it will not be amiss to outline briefly the methods of treatment which were pursued in some of the classes of cases which have no hard and fast rule for their treatment, and in some of the cases in which such rules were not observed.

In all the cases in which we had to deal with the inflamed appendix the method of removal was as follows: The incision was preferably the intermuscular, whether the case was of a simple catarrhal nature or one in which abscess was present. The appendix was freed of adhesions and brought into the wound. If the base of the appendix was in a sufficiently healthy condition to sustain the compression of a ligature, the method of choice for its removal was always the same; a double ligature was passed through the mesenteriolum, close to the base of the appendix, and cut; one end was used to ligate the appendix and the other end was thrown about the mesenteriolum and tied firmly; the appendix was then cut away from its attachment with scissors and was amputated with the cautery. The four ends of the ligatures were then tied together. The cases in which the appendix was so friable at the base that ligature was out of the question were treated by the division of the mesenteriolum in the ordinary way, the appendix was clamped at the base, divided with the cautery, and then invaginated into the cæcum by a single row of Lembert stitching, arranged in pursestring style, inserted into the cæcal wall as close as possible to the base of the appendix. I found this simple method quite sufficient to prevent escape of bowel contents, subsequent infection, and the formation of fæcal fistulæ. The material used for the pursestring was number one catgut. Pus cases were drained with cigarette drains of about three quarter inch diame-These drains were removed at the end of thirty-six hours, and rubber tubes substituted. At no time was irrigation used. The use of hydrogen peroxide was tabooed. All patients were placed in the Fowler position immediately after operation.

The burn cases upon a service are always a puzzle. Those patients who were not burnt to such a degree as to threaten life were dressed with boric ointment and this, in my opinion, is the best dressing for cases of this nature. The cases of general burns were treated as follows: All burnt tissue was removed as far as possible and wet dressings of boric acid or sodium bicarbonate were applied. The patient had enough morphine to keep him free from pain, and rectal irrigations of hot normal salt solution were given every two or three hours. Strychnine and digitalis were the principal stimulants relied upon. I have not tried the scrubbing which has so many supporters because I have not had a severe case of burns in which the patient, in my opinion, was in condition to withstand the tremendous shock of such a procedure. I have tried the treatment of burns by exposure to air without dressings and have not been impressed with the special efficacy of that form of treatment.

In the cases of empyema the treatment differed

with the age of the patient. The children did very well with a simple incision into the pus cavity, while the older patients required the resection of a rib. The drainage in both classes of cases was the same: Two rubber tubes introduced in such a manner that they protruded about half an inch into the pus cavity. I always make it a point, when operating in a sacculated empyema, to allow the junior, who subsequently dresses these cases, to put his finger into the wound and feel for himself the angle and direction of the pus cavity. In all the cases of empyema irrigation of the cavity at the time of operation, and subsequently, was rigidly avoided. After operation all these patients should be instructed in the performance of lung gyinnastics, and should be encouraged to make faithful use of the James double bottle.

The compound fractures were treated along the following lines: If there was no comminution and the skin was fairly clean, or the bones did not protrude, the limb was cleansed in about the manner usually employed in preparing a patient for operation, the fractured member put completely at rest, and the temperature of the patient watched for the first sign of infection. In very few cases was there any such infection, and in those in which it did occur it was superficial and easily controlled. The cases of more gravity, in which there was great comminution and good reason for believing that the site of fracture had been contaminated, the patient was taken to the operating room and given an anæsthetic. The site of fracture was then cleansed in a manner more thorough than would be consistent with a conscious patient, the wound opened, thoroughly flushed out, all loose pieces of bone removed, and good drainage assured by the introduction of rubber tubes to the site of fracture. I was considerably surprised at the result obtained by this method of treatment in one case in which the injury was of such severity that amoutation seemed the only resort.

The patient was a well muscled man of thirty-two. He was attacked by a buck in the deer enclosure of Bronx Park. He was tossed, and, in falling, apparently caught his foot in a crevice of some sort. I had him taken to the operating room at once and found that his foot had been practically torn off. The astragalus and the lower ends of the tibia and fibula were fractured, and the leg bones protruded through his sock and trouser leg. The bones were dirty. His foot was displaced upward upon his leg and pointed upward and inward. It was much the same condition as one would see if the finger was pushed through a hole situated about an inch from the tip of a glove finger—the protruding finger corresponding to the exposed tibia and fibula, and the tip of the glove finger to the foot, in this case. The dorsalis pedis was pulsating, but the posterior tibial artery had apparently been destroyed. It was one of the most grotesque injuries I have ever seen. The foot was scrubbed, the bones of the leg were cleaned most thoroughly, some loose pieces of astragalus were removed, and the foot was reduced to its normal relation with the leg, considerable force being necessary to accomplish this. A drainage tube, one half inch in diameter, was introduced from side to side through the remains of the ankle joint. The foot and leg were placed completely at rest. The patient was attacked with a trifling amount of superficial suppuration in the foot, but, in spite of a sharp attack of delirium tremens, made a very nice recovery and obtained practically normal function at the ankle.

In the hæmorrhoid cases the operation of choice was the clamp and cautery. None of the cases had any postoperative hæmorrhage.

In the fractures of the vault of the skull I found

that the use of "sequestration anæmia" was of considerable help. The anæmia was produced by means of tourniquets applied to one or both thighs. The room between the inner table of the skull and the surface of the brain was markedly increased by this method and the annoying bleeding from otherwise insignificant vessels in the scalp was cut down perceptibly.

All the hernias of the indirect inguinal variety were treated by the Bassini method. Pursestring repair of the femoral ring was employed in the cure of the femoral hernias, and the careful mating of structures and the overlapping of fascia was depended upon to cure the ventral hernias.

The varicose ulcers were treated by rest in bed and the induction of passive hyperamia according to the method of Bier, and the rapidity with which these usually troublesome cases recovered convinced me that this method of treatment surpasses anything I know for this condition. The pain was relieved almost at once after the application of the bandage and the improvement in the appearance of the ulcer was very pronounced within a week of the first application.

The only case of tetanus which was admitted to service was treated with vigorous doses of antitoxine and ran the usual unfortunate course. No cases of tetanus developed from the many Fourth of July wounds. Each of these cases of suspicious wounds received an immunizing course of the tetanus antitoxine.

LIPOMA OF THE KIDNEY. By O. W. H. MITCHELL, M. D., Columbia, Mo.

Lipoma of the kidney is a comparatively rare condition and is especially interesting from the viewpoint of pathology, as fat is not normally found in the kidney of man. Fat is found in the kidney epithelium after a copious intake of fatty food, but this can be considered only as physiological, as the fat is merely stored up, never to become a part, as such, of the kidney proper.

Normally, however, we do find the kidney surrounded by a fatty capsule, which according to the view of many pathologists, plays the ætiological rôle in the formation of lipomata of this organ.

Fat is to be found pathologically in the kidney only in two conditions, fatty degeneration and lipomata. The first condition we cannot say to be uncommon. It occurs in wasting diseases, in the infectious diseases, especially those which affect the kidneys, and in poisonings with arsenic, phosphorus, etc.

It is also to be found in kidneys which are primarily affected, as in acute and chronic nephritis. In the conditions mentioned, fat is to be found in the epithelium, free in the ducts, sometimes as fat droplets in the interstitial tissue. The epithelium of the convoluted tubules are most frequently attacked, although the tubes and sometimes the tufts are affected. The degeneration occurs in local areas or as a diffuse condition. The tubules may present epithelium with marked fatty degeneration or may

have lost their epithelium and are frequently to be found filled with degenerated epithelial cells and fat globules. The fat globules in the cells show no tendency to coalesce. Along with the degeneration some form of nephritis is to be found.

There have been investigators who assert fat to be normally present in the epithelium of the kidneys of persons abnormally fat, or in the condition known as obesity. Among these are Hansemann. He cites one case, that of a woman weighing 300 pounds, in which fat was found in the epithelium. In this same article he also calls attention to the investigations of Rosenstine. This observation differs widely from the general opinion according to which fat can be demonstrated physiologically, but not pathologically, in the epithelium of the kidneys. In the kidneys of fattened animals fat can be demonstrated in the interstitial tissue extending from the hilum into the medullary portion of the kidney, but not into the cortex of the organ.

Lipomata are fatty tumors which occur only rarely in the kidney and are usually small and multiple. Some very large lipomata, however, have been reported, and mention will be made of some of them under the list of reported cases. Connective tissue and plain muscle occur in variable amounts. Lipomata with a considerable amount of connective tissue have been termed, by some, fibrolipomata. Great stress has been laid on the plain muscle tissue by some investigators, especially Müller.

Ouiteanumber of cases have been reported. Müller reports five cases, Lecrampe-Loustau eight cases, Warthin, Alsberg, Virchow, Beneke, Grawitz, Ulrich. Whipham, and others have reported cases. In the Tranactions of the Pathological Society of London, Dr. Dickinson reported a case of lipoma of the kidney of enormous size, weighing six pounds, seven and one half ounces. It was attached to the right kidney, and according to Dr. Dickinson originated in the cortex of the organ. A small piece was all that remained of the right kidney. The cortical substance of the left kidney presented small areas composed of tissue like the large tumor. Dr. Bristowe described a tumor which he said was identical with the tumor presented by Dr. Dickinson. Dr. F. P. Weber described a small lipoma of the kidney very similar to the one found in this laboratory. Dr. Warthin gave a detailed description of a large fibrolipoma of the kidney. This tumor and the one described by Alsberg are the only ones, Warthin said, that demanded surgical interference. Histologically these two tumors resemble one another closely. Alsberg and Warthin agree as to the origin of lipomata of the kidney. Beneke reported cases in which in close proximity to the tumor there was a fibroblastic area in which metaplasia of the cells into fat cells could be seen.

In 1. Echo médical du nord a case of multiple lipomata of the kidney is reported. The case is particularly of clinical interest because of convulsions and epileptiform attacks from birth to death, and at autopsy the finding of the following: Enlarged kidneys with nodular neoplasms, lipomata, in the parenchyma, measuring as large as four centimetres in diameter. The tumor masses on the surface measured seven to eight millimetres in di-

ameter. The masses were soft, some porous, and varied in color from yellow to brown. Curtis, the examiner of the specimens, thought these lipomatous masses unquestionably of congenital origin.

Carl Hartwig, in a thesis, described at length a large liposarcoma of the kidney and gave also the views of pathologists regarding the origin of lipomata of the kidney. His conclusion regarding the tumor was that the tumor arose from a nodule in the capsule and not from the fatty tissue of the hilus.

The ætiology is the point which concerns us most. As was said before, normally we find no fat in the kidney, therefore from whence does this type of tumor arise? Müller's conclusions on lipomata of the kidney are as follows: I. They arise from fatty tissue and always contain some plain muscle tissue. 2. They arise from imbedded portions of the fatty capsule or from imbedded portions of the suprarenal. 3. These processes take place in embryonal life.

Horn and Ulrich assume these lipomata to arise from the fatty capsule of the kidney; either that a portion of the fatty capsule becomes transplanted into the substance of the kidney, or the tissue of the kidney, growing faster correspondingly than the fatty capsule, envelops portions of the fatty capsule. Both processes, of course, occurring during

fœtal life.

Beer and Virchow contend that lipomata of the kidney arise from connective tissue by metaplasia. Grawitz adheres strongly to the belief that they arise from misplaced adrenal tissue. Alsberg and Warthin believe lipomata of the kidney arise from metaplasia of the connective tissue of the kidney, through the transformation of the fibroblasts of the proliferating centres or of the older connective tissue cells, into fat cells. Lecrampe-Loustau divides lipomata of the kidney into two groups, intranephritic and perinephritic. The first type, he says, arise from the fat at the hilum of the kidney; the second from the fatty capsule.

Lipomata of the kidney offer a resourceful field for research regarding the origin of tumors in general. In the study of lipomata alone, of course, little practical or beneficial knowledge can be acquired, still we possibly may learn by this means the ætiology of other tumors. One must draw his conclusions from many widely varying statements from a large number of investigators. We find many who regard lipomata as arising from embryological abnormalities, e. g., Horn, Ulrich, Müller, Grawitz, Lecrampe-Loustau, and others. As large a number believe that they arise by metaplasia of the connective tissue of the kidney into fat tissue, e. g., Virchow, Beer, Warthin, Alsberg, Grawitz, Beneke, and others

All of the following views appear plausible, and in a broad classification should be included until

proved to the contrary:

I. The congenital tumors may develop, a, from fat with imbedded portions of the adrenal; b, from fat at the hilum; c, by metaplasia of connective

2. The acquired tumors may develop, a, by metaplasia of the connective tissue; b, by extension of fat tissue from the hilum into the interstitial tissue of the kidney. The last view (2,b) seems plausible, since the kidneys of fattened domestic animals show this condition to be frequently present.

CASE.-Lipoma of the Kidney, Pathological Laboratory, University of Missouri. Female, thirty-two years of age, colored. Cause of death, shown at autopsy, carcinoma of the uterus. Kidneys were dark colored, left measured 12x6x4.5 cm., right, 13x7x3 cm. Capsules stripped readily. On the surface of the left kidney, just beneath the capsule, situated entirely within the cortex of the organ, was a yellowish white area measuring 6x8x7 mm. Microscopically the tumor consisted of fat and connective tissue cells. Many capillaries found in the tumor were distended with blood. The turnor was surrounded by a hyperæmic zone. No pigmentation was found. The tissue of the kidney was congested and was in a condition of moderate catarrhal nephritis. The capsules of the tufts, which were in close nephritis. The capsules of the tuits, which were in close proximity to the tumor mass, were much thickened. The preponderance of connective tissue in certain parts of the tumor would place it in the class of fibrolipomata of some investigators. No portion of kidney tissue was seen to be entirely surrounded by tumor tissue. The tumor presented an encapsulated appearance, the capsule being formed by compressed kidney tissue. Fat droplets were to be seen in some of the connective tissue cells which lie in close proximity to the tumor. Several glomeruli were to be seen adiaimity to the tumor. Several glomeruli were to be seen adjacent to the tumor tissue. A body very similar to a glomerulus was seen within the connective tissue area surrounding the tumor, and fat droplets were found in some connective cells external to it.

211 SOUTH NINTH STREET.

A STUDY OF SPORES DEVELOPED AT AN ELEVATED TEMPERATURE.

BY BERNARD R. LEROY, M. D., Athens, Ohio.

In my studies of the bacteriology of the epilepsies and of psoriasis—two very dissimilar diseases, yet both in a measure being favorably influenced by treatment with the opsonins derived from two distinct spore bearing organisms, that have been partially described in the preliminary articles, published in the Journal, and of which more will be published in due time-I have been forced to take notice of certain phenomena which I have time and again seen in examining fluid cultures of these germs which have been first grown for from thirty-six to seventy-two hours at an elevated temperature of 158° F. (70° C.) and then at room temperature for many weeks and months.

It will be understood that all of this work has been carried out, in every particular, with the most exacting laboratory care.

For some time I have noticed, in these old cul-

tures which I would examine from time to time in the hanging drop, that often there would be strange looking particles of substances which I long mistook for particles of media, until in one particular fluid medium I noticed particles in great numbers, and some were very large, about the size of a red blood corpuscle, which were in active motion. I had noticed before a motion in these bodies but passed it by as being Brownian movements. time the motion was too decided and well regulated for me to not give it my whole attention. This caused me to observe certain strange and, to me, unknown morphological changes in the spore; slowly was I forced to believe in what I am about to describe, nor have I found anything in print which helps to explain these changes, nor have I found anything in the published works of known investigators which bears upon these changed forms, which I am now only too positive are unknown forms of the spore. So far I have succeeded in growing in liquid media those forms of several well known spore bearing bacilli.

The first to be noticed by me were very small, perfectly round particles, clear, and of a highly refractory nature; upon very close study there appeared a pale apple green color to those particles, which gave the impression that it was in constant motion within itself, that is, that it was in a continuous streaming motion from its periphery toward its centre, more to an uncertain line than to a central point; in larger particles was noticed this motion with no uncertainty, and following this up with examinations of still older cultures. I discovered the larger and more fully developed particles, those having independent motion, and ultimately the organs of locomotion.

That these forms have some pathological import I feel quite certain, that is, that the modified forms of these spores have a modified form of secretion and excretion, thus producing changed pathology.

After studying these particles in the hanging drop I would endeavor to stain these particles, using various stains and processes, but in every case I failed to do what I most longed to accomplish, and obtained as a result in every trial a small, stained dot or spore not in the least resembling the object observed under the glass, the stain or fixing being at fault. When the particles are not developed to the independent motion stage, the results of staining will be sporelike in result; when of larger particles the result will resemble artifacts.

As stated the smaller particles are round and of a pale apple green color, and have a distinctly Brownian movement; these grow slowly by the enzymes taking in substance from the culture fluid and gradually reach the size of a red blood corpuscle, when the organs of motion may be seen distinctly, when single, moving in a milling motion, i. e., not unlike the motion imparted to a long slender reed held in the hand and waved in a circular movement over the head; or, when more than one organ, then the particle itself whirls with rapid motion without advancing, nor changing its position very much. The

particle never advances through the liquid flagella, end first; it is always in the rear.

These slender organs will break loose from the particle and swim off independently, or, when two particles are in close proximity will act as feelers and seem to cover the surface of each in a way that is strongly suggestive of sexual life. The end of these slender filaments have broadened surfaces not unlike an elephant's foot in outline.

In Fig. 1 we have the simple form with apple green substance with limiting membrane, resembling a large spore, only being round in shape.

In Fig. 2 is shown the particle in a more advanced state, the apple green substance has changed its form, contains along its inner and more central border a number of bodies of a dark color, and a little more than one half of the apple green substance is covered with a clear white transparent substance not unlike albumin, shaped somewhat like a half moon, always enveloping the dark spots within the apple green substance; at this stage of growth the particle is motile and with much patience and care the filament of motion will be seen, passing as a rule out through the half moon, and the particle will advance through the fluid with the apple green substance first, or in advance.

In Fig. 3 is to be seen a still more advanced stage; the particle has assumed a more round shape, the dark spots in the apple green substance have migrated further into this substance, and the half moon is now filled with minute dark spots but not exactly similar to those found within the green substance; now will be noticed many filaments of motion, and the particle will either move away with rapidity or whirl with lightninglike speed, when it will be impossible to see the organs of motion, nor to see clearly the particle, but it will look like a brilliant, highly refractory spot in the fluid, and the motion will be mistaken for the so called Brownian movement.

In Fig. 4 will be seen one of the shapes assumed by the spore of the organism found by me in the reported case of psoriasis, and the color is the same in this as in the particles just described.

In Fig. 5 is represented a particle of many months' growth, that is it was found in a fluid medium in which I have been growing the spore bearing bacilli made use of in my study of the epilepsies. Now the globules within the apple green substance have larger granules arranged on one side with smaller granules on the opposite side, these granules are white instead of the dark color seen in the preceding cells, on the side of the cell, wherein the small white spots are found will be seen the motile organ.

In Fig. 6 the particle has assumed the dignity of a large, very pale, transparent cell, but, with much care the following organs will be seen, with a high power lens: The apple green substance is gathered within, in form of a nucleus, which occupies the central portion of the cell, containing a number of dark spots, which seem to be quite stationary, while the apple green substance streams, as described with great rapidity; in the substance without the nucleus, are seen a number of dark globules arranged around the outer periphery of the cell which project above the outer surface of the cell, giving a rough appear-

ance to this part, these are connected, by fine threadlike filaments with the organ of motion (sexual organ?), which in this instance is feeling the surface of another cell (Fig. 7) which is about the same size and found in the same culture and drop used in this study, but there are many points wherein they differ in form. This cell is composed almost entirely of apple green substance, containing but few globules of a dark material which seem to be free within the substance, this apple green substance, is streaming towards the centre as in the

Thagella are thrownou retracted as well

other cells; on one side of the cell will be noticed a sagging out of the limiting membrane of the cell and the sexual, or motile organ, is seen as if searching for the cell in its immediate neighborhood. I watched these two cells for hours, they did not attempt to move away from each other but kept up a playful feeling with their single organ. This last cell was darker in all its parts than the other cell. From their action and difference in physical form I believe them to be sexually distinct, and of oppo-

In Fig. 8, we have the organ of motion or sexual organ, as I am wont to believe. It is somewhat diagrammatic but shows the several parts as I was able to see and study them. This figure is drawn from the Fig. 7 cell, and represents the caudal portion only, the part marked (b) is an extension of the limiting membrane of the cell, (c) is the margin of the apple green nucleus, the space within the confines of these membranes is filled with a clear transparent substance, and contains a number of small, faintly darker colored granules than the other cells. I was able to see the fine threadlike filament which runs from one to the other of these granules and then uniting makes its exit in the direction of the motile organ. That it runs within the folds of the membrane which compose that organ I have no doubt, vet I was not able to demonstrate that fact clearly. It ends, as I have stated in a broadened portion at the extreme end, and this end piece seems to possess more than ordinary power, when compared with other parts of the same cell; this also was the organ or filament which I saw break away from the cell and swim away acting as if in search of its sexual mate, I regret to say that I was so nearly exhausted from my long vigil that I left the laboratory before I discovered the life end of the free filament.

In Fig. 9 will be seen particles which I found in liquid media containing pure cultures of the spore bearing organism, which I made use of in my studies of the epilepsies, after it had been boiled for more than two hundred and fifty hours, boiling the media from six to ten hours at a time, adding sterile water to keep up the measure, always boiling after such addition for some hours; then permitting the culture to rest for days after changing the media to plus alkaline in reaction. In every instance I would get a good, full growth of a pure organism in a quantity of this medium. I made experiments upon the organism by rendering the media more or less acid, thus finding that I could produce a full crop of spores, free from vegetative forms, also, I found that I could produce vegetative forms at will,

free from undeveloped spores.

These bodies (Fig 9) have no motion and resemble large cells with nucleus containing one or more nucleoli. They resemble the bodies found in

In the fluid containing an abundance of spores from the organism found by me in the scales of psoriasis, grown under the same physical conditions as described above, I have found quite a different organism which from its after actions more closely resembles the protozoon than it does the lower order to which I believe it to belong.

Fig. 10 represents the various stages of the evolution of the germ from the spore to the protozoonlike organism which is in constant act of splitting. I have seen as many as half a dozen forms hanging to one head, before they would become separated and independent germs, each to continue this wonderful form of production; during the whole time the organism is in a constant state of nervousness or quivering, turning upon its long axis with agility and seemingly to be in action constantly, nor have I as yet succeeded in reverting this form back to the original spore bearing organism, simply because I have not learned the temperature and the chemical nature of the food required, for be it understood that the spore is wholly and entirely dependent upon certain chemical conditions for its very existence and development, as is the vegetative form, and at will they can be made to produce spores entirely free from vegetative forms and vice versa. That the ordinary laboratory form of sterilizing is at fault when spore bearing organisms are to be reckoned is well understood, and either strong acid solution or the autoclave should always be used to produce sterility.

In Fig. 10, "a" represents the spore; "b," the first growth of the protozoonlike organism with the spore in centre of its long axis or body, the ends are at an angle to the body and always held patent in opposite direction, the ends do not possess motile power; "c," is the germ in a more advanced degree of development, with spore greatly reduced in size, and is being pushed towards the head end of the organism, the organism is in the act of splitting; "d," is the protozoonlike organism free from the spore, and has split into several organisms. In this stage the whole bunch is in an active state of nervousness, and will be constantly moving or turning upon itself; often I have seen many of the splitting organisms hanging to the same head each undergoing the act of splitting with that strange activity spoken of before; "e," is the single protozoonlike organism during a period of rest, it only being momentarily in space of time; "f," is the vegetative form of the organism, very delicate, very slender, and almost transparent in nature, making it very difficult to find even under a high power objective.

It will be of interest to learn the relationship of these forms to "bodies" found in certain diseases, also what relation, if any; that the last described organism, [developed from the spore bearing organism found in the scales taken from the case of psoriasis mentioned before], has to the spirochætæ. This organism, as I have developed it, will be readily found should my reported laboratory work be followed with care. I believe this form of studying the microorganism (elevated temperature cultivation) will be productive of good results if carried

Now, the most puzzling freak in spore growing that I have discovered is the fact that the culture medium in which I grew the bacilli with which I studied the epilepsies, and with which I made the above studies was first inoculated one year ago. July 6, 1907, and during the first several months I caused the medium to boil for from six to ten hours each day for one week, then permitted it to rest until a growth would develop, and after a careful examination would boil again until I have boiled that medium nearly three hundred hours. To-day the growth is alive and free from any contamination whatever. Now what, if any, action did this boiling have upon the organisms found and described in this study? Perhaps the elevated temperature by destroying certain enzymes and not others permitted the organisms to live a modified form of life. This will only be learned after a long cultural experiment with a known organism; yet from what I have found in my studies I believe that it will be demonstrated that modified forms of germs will produce a modified or changed pathology.

Another strange experiment was the taking of some of the fluid media in which I had grown the organism used in my study of the epilepsies, and by a careful use of acids and boiling I succeeded in causing the spores to so contract in size that ultimately they became ultramicroscopic in size, the medium being sterile (?) for the space of six days, having examined it with care each day during that time. In three months from the last examination I was able to detect very minute spores and a very few exceedingly small vegetative forms; in time they increased in number and size so that now I have an abundant growth of a pure strain of the bacillus. Nor is this all. I then endeavored to grow or induce the spores to grow to an abnormal size without passing into the vegetative form, and in this I succeeded so that I have seen spores as large as small mononuclear lymphocytes, this in the hanging drop; but, never could I produce a stained slide of these abnormal spores because, as I believe, they are too susceptible to surface tension and chemic

This paper is intended to be an answer to the many letters of inquiry which have reached me concerning my paper in the *Journal* for April 25th; many of these letters I have failed to answer personally for lack of time.

I also will endeavor to answer the letter which appeared in the *Journal* for May 2nd from the pen of one of New York's most eminent dermatologists, an author of the highest standing, a veritable Nestor among skin specialists. He condemns my work. This I certainly regret, but, we can say with Galileo in the fullest confidence, "E pur si muove!"

It will be understood that every stage of this

It will be understood that every stage of this work was done with a full understanding of the most strict laboratory rules.

In the many experiments carried on with the "myelin exudates" or, "artifacts" as you may wish to call them, I found that the spores held in the psoriatic scale would not germinate on solid media at any temperature whatever, nor, on any kind of solid media, and I made use of many.

The spore held within the scale will grow in liquid media only, and at an elevated temperature. 158° F. (70° C.) being the best, or, over. After which it will grow on most any of the solid media, at room temperature.

In my first article I told of the manner in which I first demonstrated the organism, in soapy water, etc., then I said "I then made a liquid medium," etc. This my New York Nestor failed to notice, else he would not have called the organisms described "artifacts," as artifacts do not swim through the fluid, nor reproduce themselves by spore production and also by a splitting process that is so constant and endless in action (see preceding pages). Nor can you make opsonins from artifacts, that will cure psoriasis!

The elevated temperature at which the organism is first grown precludes the thought of any of the vast number of organisms contaminating the fluid, but for the benefit of those who may care to know I will give the latest method which I found to be productive of good results in growing this organism.

The liquid fluid: Make a one per cent. solution of gelatin, in tap water, and place in autoclave for one hour at 266° F. (130° C.), to kill all spore life, when cool add glucose to make o.I per cent. solution, then sterilize as in other media, after bringing it to plus alkaline in reaction; now gather the scales as suggested in my first article (after having the patient go many days without medication, externally or internally of any kind whatever), then place the scales in tubes or culture bottles, and have as many as you can get, for many of the spores will not germinate; and after you have a great abundance of scales thus bottled in a greater or less amount of the fluid media, place the bottle in an incubator, or on heavy copper plate and run temperature up to 158° F. (70° C.), and hold at that point for from thirty-six to seventy-two hours, then at room temperature for days, it will be better to prepare thus several bottles, so you may be able to examine the progress of the germ or "artifact" development. You will see the germ as I described it in my first paper, within the first twenty-four hours, and, after some weeks of growth, without disturbing, you may be able to see the changes mentioned before.

Now as to the present condition of my first patient mentioned in the first article, I wish to say that he is almost free from the psoriatic eruption, and I feel confident that he will be permanently

cured.

The first effect noticed was the fine pitting of the scales, noticed in every part of his body, then the change of color in the raised, crimson colored patches of the disease, then a pitting or lowering of parts of the patches, then a lowering of the edges of the patches, then an almost ending of the scale formation, then a disappearing of the raised patches, leaving the white mortarlike stain, this disappeared leaving no scar nor stain whatever, the itching stopped early in the treatment. Then small, isolated, raised, scablike scales over the areas were noticed where the large patches had been, these went away, to be replaced by like eruptions only much smaller, these were surmounted with very fine white scales, these pass away and a still finer pimplelike eruption, very scanty, comes and goes, growing less and less every week. The patient is now almost free from any eruption whatever, and during all this time has attended to his business and has enjoyed excellent health.

I started with very small doses of the opsonins, about one half the dose given of the opsonins in a case of infection by staphylococcus, and increased rapidly in size of dose and in strength of opsonins as I noticed the fine pitting condition spoken of before, until I have given 5 c.c. of a very strong solution of the opsonins, at one treatment given in the back between shoulders deep under the skin.

In the treatment I have been governed entirely by my experience in treating with the opsonins in

other skin diseases.

In other but milder cases of psoriasis I have been having the same success and find that the same changes follow quickly as described, that the organisms are to be found in the rete I feel sure, but in just what form is a question, since I have seen the spore in the psoriatic scale grow into the vegetative form, then have I caused them to go into the spore form, and then at an elevated temperature found it changed, in fact, witnessed the change many times, from a spore to an organism not unlike a small muscle fibre like organism which propagates its kind, not by spore production, but, by splitting lengthwise as described in this article.

I have asked my friend Professor Bergey, of the University of Pennsylvania, to work out the organism from a solution of the first pure culture made and used by me in my study of the case reported. That the organism is one of a well known flora found in fresh water, I feel quite certain, and that it requires an elevated temperature to first start it growing on the human body I also feel certain; that it has not been discovered by our pathologists is due to the fact that it can change its form and very closely resemble a fine muscle fibre, or, because it is so delicately transparent that it has been overlooked, for even in a pure culture of the vegetative form it is very difficult to demonstrate under a high power lens. The full description, and cultural life, I will leave to Professor Bergey.

PULSATION OF LARGE ANEURYSMS, NONEX-PANSILE, BUT TRANSMITTED.

By SIDNEY LANGE, M. D., Cincinnati,

Radiographer to the Cincinnati Hospital.

That expansile pulsation is a pathognomonic sign of aneurysm is laid down in textbooks as an almost infallible rule. It is the purpose of these few lines to show that an aneurysm, which is large enough to impinge upon and impart its pulsation to the chest wall, will not, as a rule, execute expansile pulsations, but will simply transmit pulsations from the blood current passing through it, or more often from the heart. The smaller aneurysms do execute expansile pulsations, but the pulsation disappears as the result of the accumulating clot, before the tumor is large enough to impinge upon the chest wall and manifest its characteristic pulsations to the palpating hand.

In examining with the x ray chests containing mediastinal tumors, I have repeatedly observed that large tumors, which upon autopsy proved to be aneurysms, failed to show (upon the fluorescent screen) any signs of pulsation. Yet some of these cases, in which the tumor pressed against the anterior or posterior chest wall, gave to the palpating hand the sense of an expansile pulsation, undoubtedly a transmitted one. On the other hand, small aneurysms and nonaneurysmal dilatations of the aortic arch have invariably shown fairly active pulsations upon the fluorescent screen. The smaller the aortic tumor, the more active the pulsations seemed to be; in some the pulsations were so active that the tumor mass, when watched with the

fluorescent screen, would almost disappear during diastole only to swell out prominently during systole. In this latter type of cases it was assumed that such active pulsations could occur only in the absence of accumulated blood clot, which presupposes an unbroken endothelium, hence the diagnosis of simple aortic dilatation was advanced.

with sharp outlines. Hence expansile pulsations of mediastinal tumors may be recognized upon the skiagraph by the double contour of their shadows.

The following three cases will serve to illustrate this point:

Fig. 1 shows a *small* aneurysm of the descending part of the arch of the aorta, the expansile pulsa-

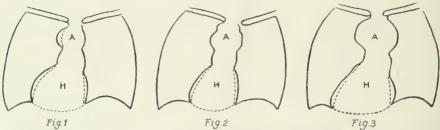

Fig. 1.—Small aneurysm of the descending part of the arch of the aorta. Fig. 2 -Aneurysm of the descending part of the arch of the aorta, somewhat larger than that shown in Fig. 1. Fig. 3.—Large aneurysm involving the entire arch of the aorta. A, aneurysm; H, heart.

But when the aortic wall gives way and thrombosis occurs (a true aneurysm resulting) the pulsation becomes less active and the diastolic recoil less marked. When the tumor mass and its blood clot (the mass of which usually increasing with the size of the aneurysm) reaches considerable proportions, there is no longer any pulsation or diastolic recoil visible to the x ray, although the palpating hand upon the chest may still feel a transmitted impulse.

Moreover, it has been shown that a nonaneurysmal tumor of the mediastinum may execute transmitted pulsations which may be visible upon the fluorescent screen. Gebauer (Deutsche medizinische Wochenschrift, 1900, No. 35) reports a case of mediastinal sarcoma which was erroneously diagnosticated as aneurysm because of its visible pulsations upon the fluorescent screen. It is therefore impossible to distinguish by x ray examination a large aneurysm from other mediastinal tumors by the visible expansile pulsation of the former.

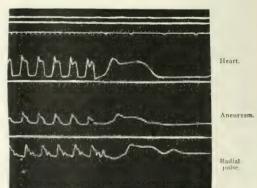

Clinically, we recognize expansile pulsation by the fact that any two points on the skin in the pulsating area appear to move apart during each pulsation. But it is readily conceivable that an aneurysm or any solid tumor when closely applied to the chest wall and receiving an impulse either from the heart or from the blood stream may transmit this impulse equally in all directions and give rise to the phenomenon of expansile pulsation. This fact was brought forward recently in a patient presented before the Association of American Physicians by Eshner. In this case a metastatic tumor of the sternum showed a marked expansile pulsation and was erroneously diagnosticated as aneurysm.

Permanent graphic evidence of the absence of expansile pulsation in certain aneurysms may be obtained upon the photographic plate. Since x ray pictures are not made instantaneously, any movement of the part skiagraphed will be evident by a blurring of the outlines of that part; thus the outlines of the heart always appear blurred upon the skiagraph plate while objects at rest cast shadows

tions of which are plainly evident by the double contour of the aneurysm. This aneurysm did not impinge upon the chest wall nor give any evidence of pulsation to the palpating hand.

Fig. 2 shows a somewhat larger aneutysm (verified by autopsy) involving the arch of the aorta, which had produced a bulging of the upper part of the sternum; yet no pulsation was visible or palpable over the sternal prominence. The contour of the tumor upon the skiagram is fairly sharp, which speaks against active pulsation. This tumor pressed upon the trachea, causing extreme dyspnæa, for the relief of which a low tracheotomy was done and a tube inserted. Looking directly at the compressed tracheal walls through the tracheotomy opening no pulsation could be seen.

Fig. 3 shows a large aneurysm (verified by atuopsy) involving the entire arch of the aorta. This mass produced a bulging of the chest wall, over which the supposedly expansile pulsations

110. 4 - Sphygo,ograph of the heart, aneurysm, and radial pulse.

could be felt. Upon a fluoroscopic examination no pulsations could be seen, while upon the skiagram the outlines of the tumor mass appeared clear cut, giving no evidence of pulsation.

The accompanying sphygmograph further confirms this observation. It was made from the

aneurysm shown in Fig. 3.

Comparing the tracing obtained from the aneurysm with that of the heart we note that the pulsations are practically synchronous and that the apex of the aneurysm tracing is as sharp as that of the heart, while its descent is more sudden. Furthermore, the aneurysm tracing bears the closest resemblance to that of the radial pulse, being that of an ordinary arterial pulse.

If the pulsations of the aneurysm were truly expansile, we would expect a slower rise, a more sustained summit, and a slower descent than that of the

heart or the radial pulse.

AN ADJUSTABLE LENS FOR OBLIQUE ILLUMINATION OF THE EYES.

By S. W. Newmayer, M. D.,

Philadelphia, Wills Eye Hospital.

Oblique illumination of the eye is one of the important methods of examining the cornea, the anterior chamber, the iris, and the lens. By focusing the rays of light through a lens of two or three inch focal distance, information is ofttimes obtained which cannot be procured by other methods. Abnormalities or foreign bodies located in these media can readily be diagnosticated. Every physician has experienced the difficulty of maintaining proper illumination of the eye while removing a foreign body. In most cases an assistant is necessary to hold the lens, and even then the light is more often shed where it is of little value to the operator. To

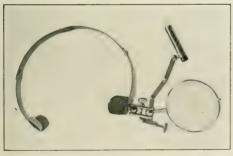

Fig. 1 -- Photograph of adjustable lens, with the electric lamp attachment.

overcome this difficulty I devised the following lens and illuminator. It consists of a lens of the required focal strength set in a frame, with a handle at the end of which is a ball knob. This knob fits and works in a socket attached to a head band. By placing this band over the head of the patient, who is seated about two feet from the source of illuminators.

nation, the operator can adjust the lens in position to throw the light where required and maintain it without any assistance. This gives the physician full use of his hands for operating. There are at-

Fig. 2.-Photograph of instrument in position on patient.

tachments for electrical or candle illumination, if desired. The entire apparatus, including the head band, is readily taken apart and can be folded into a small case.

1306 PINE STREET.

The Attendance at European Universities.—In stating that in 1907 there were in Europe 125 universities, which were visited by 228,732 students, Vice-Consul James L. A. Burrell, of Magdeburg, sends details. Of these the University of Berlin had the largest number of students, viz., 13,884; next came Paris with 12,985, Budapest with 6,551, and Vienna with 6,205. The list by country follows:

| | No. of | |
|-----------------|---------------|-----------|
| Country. | Universities. | Students. |
| Germany | . 21 | 40.000 |
| France | . 16 | 32,000 |
| Austria-Hungary | | 30,000 |
| England | | 25,000 |
| Italy | | 24.000 |
| Russia | . 0 | 23.000 |
| Spain | | 12,000 |
| Switzerland | | 6,500 |
| Belgium | | 5.000 |
| Sweden | | 5,000 |
| Roumania | | 5,000 |
| Holland | - 5 | 4,000 |

The smaller countries—Greece, Norway, Portugal, Denmark, Bulgaria, and Servia—have each one university.—Science.

Our Beaders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows: LXXIX.—How do you treat sick headache?

LXXX.—How do you treat asphyxia neonatorum? LXXX.—How do you treat asphyxia neonatorum? (Closed November 10, 1008.)

LXXXI.-How do you treat chronic eczema? (Answers

due not later than December 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the Journal. Our readers are asked to suggest topics for discussion. The prize of \$25 for the best essay submitted in answer to question LXXVIII has been awarded to Dr. Charles Floyd Burrows, of Syracuse. N. Y., whose article appeared

on page 842.

PRIZE OUESTION LXXVIII.

THE TREATMENT OF ACUTE CORYZA.

(Concluded from page 944.)

Dr. E. S. McKee, of Cincinnati, observes:

Ubi irritatio ibi fluxus is more true in the Schneiderian membrane than elsewhere. Zuckerkandl demonstrated that the arteries which supply the nose are different from those in many other parts of the body, largely because they enter through bony foramina alongside the veins. If irritation occurs, a flow of blood is sent through the artery, it enlarges but does not push aside the vein as in parts where the tissues are soft, but compresses the vein confined with it in the bony canal, and thus by increased inflow and diminished outflow augments the congestion both coming and going. This vascular mechanism is somewhat unique, and a full understanding thereof is of

We meet coryza most frequently at the changes of the seasons, but it is with us always. Most cases probably depend on a microorganism, but some on irritation, while ingestion of meats and wearing heavy clothing seem to predispose.

Preventative treatment consists largely of cold sponge baths, with regulation of diet, elimination, light clothing, and exercise in the open air. Some, however, can not endure cold baths. The recumbent posture on account of the force of gravity aggravates a case very much and should be avoided

The treatment should consist in, first, an alkaline solution to cleanse, then a curative solution, then a

soothing solution dissolved in oil.

To abort an attack administer rather large doses of quinine. The following combination is of value

| B | Morphine sulphate, |
|------|------------------------------------|
| | Atropine sulphate, |
| | Comp. powder of ipecac,7.0 grammes |
| 7\/ſ | Quinine sulphate,4.0 grammes |

S. One capsule at bedtime with a hot drink, repeated once or twice during the day, if necessary.

A good internal remedy consists of sweet spirit of nitre, and aromatic spirit of ammonia, equal parts, one teaspoonful every four hours to an adult. Some attacks will abort from:

| B | Ammonia | water | , | | | 1.33 gran | nmes ; |
|----|-----------|--------|-------|------|----------|------------|--------|
| | | | | | | I.o gra | |
| | | | | | | 4.0 gran | |
| | Distilled | water, | | | | 8.o gran | nımes. |
| M. | S. Five | to ten | drops | on a | blotter, | and inhale | every |

two hours. Frequent inhalation of boiling hydrogen peroxide the first night of the attack will often abort

Threatening deafness from coryza should be met with the following salve, painted on the nasal surfaces as far back as possible several times a day:

| P_{k} | Menthol, | | | 0.2 | gramme. |
|---------|-----------|-------|------|-----|----------|
| | Cocaine, | | | | gramme; |
| | Petrolatu | ım, . | | 150 | grammes. |
| M | | | | | |

Purulent discharge in corvza should be treated by thorough irrigation with hydrogen dioxide combined with equal parts of sodium bicarbonate, two per cent. solution, followed by a two per cent. solution of

Ointments are a convenient and enduring, though uncleanly, method of treatment. They are best administered in collapsible tubes with long nozzles. The ointments prepared with the suprarenal preparations are beneficial. These can be prepared as

| $\mathrm{P}_{\!\scriptscriptstyle B}$ | Suprarenalin, | |
|---------------------------------------|-------------------------------------|----------|
| | Normal salt solution,q. s. ad. 16.0 | |
| | Wool fat, | |
| | Petrolatum,18.0 | grammes. |

This is a strength of 1.1000.

Snuffing powders are beneficial and should be made light and fluffy, very finely powdered, and intimately triturated. A good one is:

| P_i | Boric acid, x, | gramme |
|-------|---------------------|---------|
| | Thymol iodide, | gramme |
| | Bismuth salicylate, | gramme |
| | Sodium chloride, | gramme |
| | Powdered elm,50.0 | grammes |

Another is

| | 7.1.1.1.1 |
|--------------|--------------------------------------|
| \mathbf{R} | Menthol, gramme; |
| | Thymol, gramme |
| | Eucalyptol, gramme |
| | Orris root, |
| | Sodium chloride 6.0 grammes |
| | Powdered elm,50.0 grammes |
| | Hydrastine hydrochloride,4.0 grammes |
| | |

Local treatment should be preceded by the snuffing, spraying, or douching of the nares by an alkaline or antiseptic solution. Those made by dissolving Seiler's or Thrasher's tablets in water are good. A simple alkaline and antiseptic nose wash which can be readily made up at home is as follows: Salt, one half teaspoonful; soda, one teaspoonful; phenol, ten drops; water, one pint. This is best used lukewarm, the patient stooping over, snuffing through

the nose and spitting out of the mouth. The addition of a bit of carmin gives this simple mixture a more medicinal appearance and enables the patient to see that it has passed through the nose and out of the mouth. The most valuable mixture for the relief and cure of coryza used locally by means of atomizer, pledget of cotton, or medicine dropper, the patient assuming the recumbent position for fifteen minutes after application, is as follows:

Dr. John W. Scott, of Gordonsville, Va., states:

The treatment of acute coryza may be prophylactic, abortive, or palliative. "A cold in the head" should never be regarded as so trivial as not to re-

ceive prompt and careful attention.

Eliminating acute nasal catarrh as a symptomatic lesion in measles, scarlet fever, smallpox, whooping cough, typhoid fever, influenza, diphtheria, scurvy, diabetes, erysipelas, and rheumatism, as well as the rhinitis produced by the ingestion of iodine, and that caused by the passage of atropine into the nostril through the lachrymal canal when this substance is instilled in the eye, our attention is called and our efforts directed toward combating the predisposing causes. No individual case can be inteligently managed without an understanding of the underlying current productive of the condition.

Nasal deformities, postnasal adenoids, and chronic pathological conditions of the nasopharynx and parts adjacent; syphilitis, rheumatic, gouty, and tuberculous diatheses; menstruation in nervous females; indigestion, excesses of every kind, more -especially excessive indulgence in alcohol, tobacco, and in nitrogenous foods; venery; fatigue; poorly ventilated living rooms; the wearing of too heavy clothing, underwear particularly, are to be regarded as predisposing, while as exciting causes may be briefly laid down vaginal secretions from the mother in the newborn, chilling, exposure to draughts, while perspiring, wetting the head with cold water with some persons, exposure to a lower temperature after a hot bath, too close contact with an affected person, and the use of towels or handkerchiefs which have been used by an affected individual, and the inhalation of certain fumes and of dust. Atmospheric conditions should also enter this list, especially cold and damp conditions:

With the actiology always in view, in this as in every other diseased condition, we are brought to the consideration of the abortive treatment of acute rhinitis, the success of which is conditioned on the early employment of the remedies thus directed. A hot bath, followed by a brisk rub with a bath towel, rest in bed, with bed clothing sufficient to keep the skin active without deranging the digestion by the use of diaphonetics. The temperature of the room should be about 70° F., and the air pure. If the patient is robust, five grains each of calomel and Dover's powders are given in one capsule, and in four hours followed by a brisk saline purge. In

less robust persons the following:

 B
 Codeine phosphate, gr. i;
 gr. i;

 Powd. camphor, gr. v;
 gr. v;

 Extract of belladonna, gr. ss.
 gr. ss.

S. Take one capsule every three hours.

Two hours after the last capsule give calomel, grain iii, and follow this in three hours by a saline purgative. The patient is to be isolated, and instructed to carefully inhale, for a few seconds every two hours, from a bottle, formalin. During the dry stage the nostrils may be occasionally douched with hot normal salt solution, but this should be immediately discontinued so soon as the watery discharge commences, but the formalin should be continued, but the danger of irritation therefrom is to be guarded against. The use of the handkerchief should be advised against, so far as cleanliness allows, and the skin around the nostrils and of the upper lip protected by some bland salve. The diet should be light, and all stimulants and tobacco interdicted.

After thirty-six hours the patient may leave his room, and if not well palliative treatment commenced.

Every effort should be directed toward improvement of the general health, and any diathesis should have appropriate attention, while the avoidance of every exciting cause is urged. So long as the nasal discharge is thin, be it serous or mucous, the nostril should be cleansed three times daily with some alkaline antiseptic, and sprayed with some oily substance. Liquid petrolatum is very efficient. In this stage, as in the first, cocaine solution, two per cent., and solution of adrenalin chloride, in combination, applied to the nasal mucosa, give brilliant results, but the reaction is, in others, worse than before its use, and cocaine should never be given the patient to use at his discretion.

The irritation and soreness left in the nostrils after other symptoms have subsided is relieved by painting the mucous membrane with a solution of fifteen grains silver nitrate to one ounce of water.

In children the nostrils should be frequently carefully cleansed, the oily preparation, as petrolatum, applied thereto, and the general condition attended to.

Sometimes minute doses of Dover's powder or paregoric have a pleasing effect.

Dr. J. P. McQuillin, of Brooklyn, N. Y., says:

The treatment of acute coryza depends on the stage of the disease. The attack may be divided into two stages, that of engorgement and of secretion.

During the stage of engorgement the proper treatment is to deplete the bloodvessels. This may be done in two ways, by constriction and by depletion. I mention the second way only to condemn it.

You should advise the patient to remain at home and in a room with a warm, moist atmosphere. This may be accomplished by keeping the room filled with steam in the winter time.

You should first prescribe some energetic cathartic, which by withdrawing fluids from the intestinal tract, relieves the congestion in the nasal

cavities. I now order ten grains of Dover's powder, which acts nicely in two ways, by relieving the pains and aches which the patient complains of and by causing a profuse perspiration, and thus relieving the congested capillaries of the nasal tract.

As a local application to the engorged mucous membranes the following usually gives considerable relief. A few drops of the solution should be dropped into each nostril, every three hours, for not more than four times:

| \mathbf{R} | Cocaine hydrochloride,gr. ii; |
|--------------|-------------------------------|
| | Camphor,gr. 1; |
| | Rose water,gtt. ii; |
| | Liquid petrolatum, |

For the frontal pains, which are so distressing, hot cloths to the forehead will give considerable relief.

Should the patient not be able to give up and remain in the house, he may take a capsule containing the following drugs:

| \mathbf{B} | Powdered camphor, | | |
|--------------|----------------------------|--------------------------|----|
| | Extract of belladonna, | | |
| | Quinine brom., | gr. | |
| M. | S. One capsule to be taken | every hour for four dose | 25 |

M. S. One capsule to be taken every hour for four doses, or until the throat becomes dry, after which every three hours will be sufficient.

One capsule to be taken every hour for four doses, or until the throat becomes dry, after which every three hours will be sufficient.

If, notwithstanding this treatment, the disease runs on to the stage of secretion, or should the paient wait to consult you until the membranes are secreting freely, the treatment will then consist of the use of astringent solutions. The disease will, if now left alone, run a natural course, the secretions first becoming watery, alkaline, and irritating to the skin surfaces over which they run. This secretion will gradually increase in amount until almost a constant stream runs from the nostrils and the patient becomes exceedingly miserable. After two or three days the secretions become less in quantity and the character of it changes. It now becomes thicker, and gradually turns to a yellowish, offensive discharge, which after a few more days slowly lessens and stops. The whole cycle from the first symptoms to the final cessation of the discharge taking a week or ten days.

To cleanse the nostrils any of the alkaline solutions or plain salt and water will answer, after which an astringent solution such as the following acts well:

| B | | s leaves, |
|----|---------------------------|-----------|
| | | , |
| | | |
| M. | S. A few drops in each no | ostril, |

There are usually no complications following an attack of corvea. Occasionally you will get trouble with the middle car or the frontal sinus, the treatment of which does not properly come under the title of this paper. Occasionally the membrane over the turbinate bones is left in a flabby, soggy condition, due to the soaking it has had with the profue discharges. If this condition occurs it will require applications of stronger astringents or possibly the cautery.

There is one other plan of treatment which from personal experience I have found to be very ef-

ficacious. On the outbreak of an attack of acute coryza I have found that a change of climate, even though the distance be short from home, will invariably cut it short. I have in twenty-four hours stopped an attack, which usually runs over a week, by simply running away from it by means of a slight change of climate.

Correspondence.

LETTER FROM LONDON.

Unqualified Dentistry.—A Complaint by Nurses.—Cataphoresis.—The Investigation of the Sleeping Sickness. —The Death of Mr. William Knight Treves.

London, November 3, 1908.

A very important case affecting the practice of dentistry has recently been tried in the courts. The prosecution was undertaken by the British Dental Association, a body that has always proved zealous in defense of the professional rights of dentists. The original case was heard before Mr. A. C. Plowden, a metropolitan magistrate, who convicted Harry John Barnes and fined him 20s., with £3, 3s. costs, for offenses under the Dentists' Act of 1878 and the medical acts. The complaint was that Barnes, not being registered under the Dentists' Act of 1878 and not being a legally qualified medical practitioner, unlawfully used the following description, namely: "H. J. Barnes, finest artificial teeth at moderate prices; extractions. Advice free. Hours, 10-7. English and American teeth. Painless extractions. On behalf of the defendant it was contended that he did not use any name, title, addition, or description implying that he was registered under the act in question, or that he was a person specially qualified to practise dentistry under the Dentists' and the Medical Acts. On the evidence before him Mr. Plowden convicted, and later, on the application of the defendant, stated a case for the consideration of the Court of Appeal. The case was heard by the Lord Chief Justice, Mr. Justice Bigham, and Mr. Justice Walton, who, after a long and careful hearing, in which the appellant was represented by the most able counsel, agreed unanimously in sustaining the verdict of the magistrate. The main contention of the appellant's counsel was that the words "specially qualified" in Section 3 of the Dentists' Act referred, not to a person's qualifications as an individual, but to some one or more of the special qualifications mentioned in the act. The Lord Chief Justice and his fellow judges thought there was sufficient evidence to support the view of the magistrate that these words on the appellant's windows and doors meant that he had such a skilful qualification that it enabled him to extract teeth with little or no pain, that he had a special qualification in extracting teeth and in fitting in other teeth. The effect of this judgment is likely to be revolutionary so far as unqualified dentistry is concerned. It follows that no unqualified person can publish any advertisement implying that he has special skill in dentistry. It is no longer necessary, in order to become liable under the Dentists' Act, that the unqualified person style himself dentist or dental surgeon, or use letters implying that he has a qualification; the mere claim to the the result of their efforts.

performance of certain ordinary acts incidental to the practice of dentistry is apparently sufficient to bring him within the purview of the act. The question naturally arises, If the law can thus be interpreted in the case of dentistry, why can it not be equally applicable in the infinitely more important art of medicine, of which dentistry forms a subordinate branch? The suppression of quack medicine is of vital importance, not only to the medical profession, but also to the public, and the whole energies of a united profession are required to bring the matter forward in a way likely to lead to practical reforms. In the mean time the verdict is a great triumph for the registered dentist and the British Dental Association, and they are to be congratulated on

The Nurses' Registration Bill is in the committee stage of the House of Lords and will soon be before the House of Commons. The final points for consideration were the clauses for the registration of existing nurses. It was decided that within three years any person of good character above twentyone years of age should be entitled to registration if she produced a certificate of satisfactory training at a hospital or institution approved by the Council. Another question affecting nurses has been freely discussed in the columns of the Times and other journals lately. This is the living-in system. Many nurses have complained of the despotism that goes on in the large hospitals and nursing institutions. The freedom of the nurses is greatly restricted and in these days of feminine emancipation it is no wonder that the monastic tradition of despotism is challenged by the nurses. As one journal aptly expresses it, "we shall probably soon see the emancipated hospital nurse disporting herself sans uniform on her off duty hours without pass, permission, or any of the other little tyrannies so dear to the hearts of matrons.'

Since Professor Leduc, of Nantes, read his paper at the annual meeting of the British Medical Association, in 1907, on ionic medication, a great deal of work has been done on this subject in England. Professor Leduc proved the efficacy of this method of local application of drugs by a striking experiment. He soaked a pad of lint in strychnine solution and strapped it to the ear of a rabbit. He then passed a current through the wet pad and the rabbit's ear, with the consequence that a rapidly fatal result occurred from strychnine poisoning. Ionic medication, or cataphoresis, has now been applied to the treatment of various conditions-skin affections, warts, ringworm, sciatica, and rheumatism. The treatment of rodent ulcer by zinc ions has been very successful. Among the cases already reported may be mentioned a case of rodent ulcer in the University College Hospital, which was treated by zinc ionization in the following manner: The ulcer, which was of about the size of a threepenny piece and situated on the chin of an elderly man, was thoroughly treated with a solution of sulphate of zinc, then covered with lint soaked in a similar solution, and a positive zinc electrode applied to the lint. A moderate current was then passed through the lint and ulcer for some ten minutes, as a result of which the malignant ulcer rapidly healed. Copper ionization has been tried with success in the treatment of ringworm. Salicylate of sodium and iodine have been used in this way for sciatica.

Captain F. Percival Mackie, of the Indian Medical Service, has been selected by the government of India to join Sir David Bruce's expedition to Uganda

to investigate sleeping sickness.

The death occurred on October 14th of Mr. William Knight Treves, F. R. C. S., brother of Sir Frederick Treves, He was resident surgeon to the Royal Sea Bathing Hospital, Margate, and afterward surgeon and consulting surgeon. He had written several works on surgical tuberculosis. He had a large practice as a consultant in Margate and the district.

Therapentical Hotes.

Angular Conjunctivitis is advantageously treated with zinc salts, according to a writer in the November number of *The Practitioner*, who recommends the application of the following lotion:

 B
 Boric acid,
 gr. viii;

 Zunc sulphate,
 gr. ii;

 Distilled water,
 ad 5i.

 M. Ft. Collyrium.

This lotion should be diluted with an equal part of water, which has been previously boiled, and used *warm* to the conjunctival sac.

Ointment for the Relief of Pruritus Ani.— Lockhart Mummery (*The Practitioner*, November, 1908) prescribes the following ointment, which is said to give relief in itching about the region of the anus, especially if applied at night:

| B, | Calomel, |
|----|--------------------------|
| | Bismuth subnitrate, |
| | Tincture of aconite, |
| | Glycerin, |
| | Outment of elder oflwers |
| | Ft. unguentum. |

Treatment of Cardiac Troubles of the Menopause.—J. Ferreira (Bulletin général de thérapeutique, October 23, 1908) advises the use of the following mixture in the treatment of the palpitation and precordial pain which so frequently accompanies the cessation of the menstrual flow:

| \mathbf{R} | Camphorated tincture of opium, | .3v; |
|--------------|---|------|
| | Fluid extract of cactus grandiflorus, | xv; |
| | Fluid extract of viburnum prunifolium, | |
| | Fluid extract of piscidia etrythrina, | |
| M. | et Sig.: Twenty drops in water night and morn | ing. |

Application for Orchitis.—The following ointment is recommended to be rubbed into the skin (Journal de médecine de Paris, October 24, 1908):

B Synthetic guaiacol, 3iiss;
Methyl salicylate, 3iv;
Lard, 3iii.

M. Ft. unguentum.

Tonic syrup of the following composition is prescribed by Renon (Journal de médecine de Paris, October 17, 1908):

| B | Extract of cinchonagr. xiv | v : |
|----|------------------------------|-----|
| | Sodium arsenate,gr. 3. | |
| | Glycerin, | 1 |
| M. | Syrup of bitter orange peel, | 11. |

NEW YORK, SATURDAY, NOVEMBER 21, 1908.

SANATORIUM ADMINISTRATION.

According to an article in the New York Tribune last week, some of the patients at the Tuberculosis Sanatorium at Otisville struck when they were asked to do some light work. The sanatorium, as our readers are probably aware, is conducted by the Department of Health for the care of hopeful cases. While treatment is absolutely free, the patients are admitted with the distinct understanding that they shall perform such service as the resident physician may assign. In the present instance it appears that a number of patients were directed to clean up the dining room after meals, and not only refused, but sent letters to New York complaining of the "hard labor" to which they were subjected.

One of the strongest arguments made against tuberculosis sanatoria in the past has been that, while the patients might be discharged healed in body, they were often so disorganized morally that they became a burden either to their family, their friends, or the community. Although these patients had been used to hard work all their lives, the prolonged period of idleness in the sanatorium developed in them such an aversion to labor as to seriously impair their value to society. All who have had experience with sanatorium administration know that this is often the case. Another argument of considerable weight was directed against the economic value of the institutions. It was pointed out that the cost of treating the patients was often entirely out of proportion to the value of the individual's life to the community. Fortunately it is coming to be realized that the suppression of tuberculosis is primarily a vast social and economic problem, and emphasis is now rightly laid on economy in the construction and administration of the sanatoria. The era of imposing buildings, we hope is past. The governing principle now is to obtain the lowest cost compatible with efficiency. Moreover, from a purely medical point of view, many observers insist on the physical benefit to the patients when they are compelled to work in proportion to their

The wisdom of the requirement of service at the Otisville Sanatorium is therefore apparent. Certainly the "strike" of a few malcontents will not cause the rule to be abandoned. A curious commentary on the complaint concerning "hard labor" was furnished by the frantic pleading of the dismissed strikers to be readmitted. What the outcome of these pleadings has been is not stated. To an outsider it would seem that, since these patients had had their opportunity, other applicants should next be favored.

GYNÆCOLOGY AMONG THE INSANE.

It is a subject worthy of comment when we find practitioners of different specialties in medicine working together with the view of arriving at results through their combined efforts. Further, it is all the more a subject for congratulation to find such cooperation active in our hospitals for the insane, for it is unfortunately a widespread though careless deduction that little can be done for the mentally ill. The therapeutics of mental disorders, on the contrary, is large with promise that comes from various quarters, and in calling attention to the report of Dr. LeRoy Broun of his work on 411 patients treated in the Manhattan State Hospital (American Journal of Obstetrics, October), it affords us an opportunity for congratulating both the hospital on having a superintendent who places his material at the disposal of the surgeon, and the surgeon who has given such a sensible and common sense résumé of his work. It is a model of efficient work, modestly brought forward and rational

Dr. Broun's thesis is that the mentally ill, suffering from disease or disorder of the pelvic viscera, are just as much entitled to have those defects remedied as people not so affected, and that if such local treatment may be serviceable in bringing about improvement in the mental condition, so much the better. And, as might be conservatively expected. Broun finds that good results do follow for many patients, and in those, speaking on an individual basis, in whom it might reasonably be expected. Better physical health means better mental health, and in many instances a diseased pelvic viscus is a sufficient cause for turning the balance of mental health in the wrong direction.

Dr. Broun offers no panaceas. He cures no incurable diseases. He offers no tempting hypotheses of occult character to explain the results. He rests on a record of common sense performance that treats the gynæcological conditions as gynæcological conditions and gets mental results as well. Individualization, not generalization, is the guiding principle; he does not cure dementia præcox or manic depressives. He helps certain individuals, independently of their mental troubles, because they need skilled gynæcological treatment, and fortunately the needs of the mentally ill in this respect are not disregarded.

THE OLIVE OIL TREATMENT OF BILIARY LITHIASIS.

The administration of olive oil in gallstone troubles has maintained its vogue with many practitioners in spite of its having been lately decried on the strength of the statement that the oil did not come in contact with the diseased parts. Professor Köster, of Leipsic, has made the therapeutical value of olive oil in diseases of the gallbladder the subject of special study and experiments. For his experiments he has used fifteen dogs and six cats. Antivivisectionists may here be reminded that their frequently repeated statement that the conclusions based upon animal experiments cannot be adapted to man, on account of the vast distinction of vital conditions in man and animals, is absolutely erroneous. The -conditions under discussion are not peculiar to mankind, but are fundamental processes of the histological structure and the innervation of the organs of digestion, as well as of the mode of nutrition, common to man and to the cat and the

The conclusions which Dr. Köster reaches in his essay on Fettresorption im Darme und Gallenabsonderung nach Fettdarreichung (Leipsic, 1908), are of therapeutical value in the treatment of gallbladder diseases. He has proved that even small quantities of oil injected through the rectum will reach the valve of Bauhin, and on account of this the contents of the large intestine become softened and are thus rendered more easily movable, a fact of importance to the gallstone sufferer, who so often is constipated. The influence of oil treatment is not a direct one on the formation of bile, but the administration of oil by the mouth or rectum produces a repeated discharge of that secretion, thus inducing the gallbladder to empty its contents frequently, and in this way preventing stagnation of bile in the gallbladder, to be followed by the formation of gallstones.

The introduction of the oil should preferably be done by the rectum, as the stomach and the small intestines will thus be saved from catarrhal attacks, which are said to be frequent sequelæ of taking large quantities of oil by the mouth. Whether we use sodium acid oleate or olive oil with a one per cent. solution of sodium hydroxide in equal parts, plus a 0.6 per cent. sodium chloride solution, is of no import. Thus the old empirical remedy for gallstone disease, olive oil, the use of which was repudiated on theoretical grounds, has been proved to be of practical value.

THE REPORT OF THE SURGEON GENERAL OF THE ARMY.

Surgeon General O'Reilly's report for the year ending June 30, 1908, has been received at this office. It makes 179 octavo pages. It is gratifying to learn from the report that the increased inducements now offered for the Medical Corps have attracted more men than was the case under former conditions, and that there is every prospect of obtaining a large class of candidates for this year's session of the Army Medical School, but it was not thought probable at the date of the report that the fifty-five vacancies in the corps (twenty-one remaining from the old organization and thirty-four new ones authorized by Congress) would all be filled this year. The surgeon general announces that he has met with notable success in his efforts to build up the new Medical Reserve Corps with desirable men by inducing prominent physicians, surgeons, hygienists; and laboratory workers throughout the country to head it. This he attributes to the patriotism of a large percentage of the medical men with whom he has communicated. This corps, it is expected, will gradually do away with the need of contract surgeons.

THE WATER SUPPLY OF PHILA-DELPHIA.

An interesting article descriptive of the past and present water supply of the city of Philadelphia is to be found in the *Journal of the Franklin Institute* for November. The paper is by Mr. John C. Trautwine, Jr., who was the chief of the Bureau of Water in Philadelphia from 1896 to 1899. There is a vein of quiet sarcasm running through the paper, which can be appreciated only by those who are familiar with Philadelphia politics. But the paper in general shows some of the obstacles that scientific men in charge of public works are obliged to overcome, and it shows particularly the nature of the water problems that confront a city of the size of Philadelphia, which is now estimated to have a population of 1.532-732.

THE FUNCTION OF THE THYMUS GLAND.

Inasmuch as the thymus normally undergoes atrophy when the period of active growth of the individual comes to an end, it has been assumed by some observers that its special function is that of promoting growth. Plausible as the assumption may be, it is not borne out by some experiments on the effects of removal of the gland in young animals that were recently undertaken by Alexander MacLennan, M. B. C. M., of Glasgow (Glasgow Medical Journal, August). Though he does not profess to have arrived at a complete knowledge of the function or functions of the thymus, he has certainly made some valuable observations and drawn several practical deductions.

The organ has been regarded as a lymphatic gland, and MacLennan concedes that it may be such a gland, but he remarks that it is so specialized as to be something more, and he declares it to be one of the series of glands which, by their internal secretions, regulate the various functions of the body. He thinks that it is really an accessory gland, because its function may be taken up by some other organ, the spleen, for example. Simultaneous removal of the thymus and of the spleen, he says, invariably causes death. By itself, the thymus does not seem to be essential to life, for there are cases on record in which there had never been a thymus; moreover, removal of the gland, dangerous as the operation itself is in young animals, does not necessarily give rise to death.

MacLennan thinks that the thymus and the thyreoid glands are closely associated developmentally, anatomically, physiologically, and pathologically. In two operations on the human subject he has found the thymus continuous with the left lobe of the thyreoid, and he finds that a diminished amount of thyreoid is sufficient after removal of the thymus. There is a type of exophthalmic goître, he says, in which removal of the thyreoid gland is followed by sudden death, and in those cases, on post mortem examination, the thymus gland is found enlarged. It is assuredly correct, he thinks, to impute sudden death to an enlarged thymus in certain cases of the status lymphaticus, so he says that, when thyreoidectomy is deemed necessary in cases of exophthalmic goitre, he would recommend that the thymus gland be first sought for and, if it is enlarged, that it be removed as a preliminary to thyreoidectomy.

In some morbid conditions, notably laryngismus stridulus, removal of the thymus has given good results, and the result is not mechanical, but due to the internal secretors of the

thymus. "In cretins," says the author, "thymusectomy, by reducing the necessity for thyreoid secretion, will be beneficial, and ought to be tried." In children who present a fulness over the suprasternal notch during expiration, straining, or coughing, he continues, special care ought to be taken during surgical anaesthesia, which "ought to be of the lightest possible."

THE MEMORY OF MAJOR CARROLL.

It was a graceful act on the part of the University of Maryland, at the recent celebration of "Academic Day," to erect a tablet to the memory of the late Major James Carroll, of the Army Medical Corps, and to provide for an address upon Major Carroll's life and work, which was delivered by Dr. William H. Welch. Major Carroll received his medical diploma from the university, and subsequently the degree of LL. D.

MEDICAL PRACTICE AND THE CHURCH.

In the Journal of last week we cited the letters of Dr. J. Leonard Corning, Dr. Joseph Collins, and Dr. M. Allen Starr, published in the New York Times, with reference to the extension of the "Emmanuel movement" to New York. Quite by accident, the clear and incisive letter of Dr. B. Sachs, deprecating the movement, was not referred to. Dr. Sachs's letter was a dignified communication, and we take pleasure in calling attention to it now.

THE NEW SURGEON GENERAL OF THE ARMY.

The nomination of Colonel George H. Torney, now commanding the Army General Hospital at the Presidio of San Francisco, as the successor of Brigadier General O'Reilly, who retires in January, as surgeon general of the United States Army, will place at the head of the Army Medical Corps an officer eminently qualified for the distinction which is conferred upon him. It is understood that the President decided not to appoint as head of the corps any officer who had only a short time to serve prior to the date of his retirement, and that this decision excluded several applicants who had otherwise strong claims to preferment. Colonel Torney, we believe, will not retire until June, 1914, so that he will have four years and a half of active service at the head of the Medical Corps. During the war with Spain Colonel Torney was in command of the hospital ship Relief, and subsequently commanded the Army and Navy General Hospital and the First Reserve Hospital at Manila.

Hews Items.

Rochester, N. Y., Academy of Medicine.—The regular meeting of this academy was held on Wednesday, November 18th, under the auspices of Section III. The Dead Man's Curve was the title of the paper of the evening, which was read by Dr. Thomas Jameson.

The Resident and Ex-Resident Alumni Association of Mt. Sinai Hospital, Philadelphia, elected the following officers at a recent meeting: Chairman, Dr. J. L. Werner; vice-chairman, Dr. B. H. Mann; treasurer and secretary, Dr. Michael Austin; historian, Dr. J. Levy.

The Bisset Hawkins Medal of the Royal College of Physicians, London, has been awarded to Sir Shirley Murphy, medical officer to the London County Council, in recognition of his services in the promotion of public

recognition of his services in the promotion of public health. The prize is awarded every three years.

Allegany County, Md., Medical Society.—At the annual meeting of this society, which was held in Cumberland, Md., recently, the following officers were elected: President, Dr. Tmothy Griffith, of Frostburg; vice-president, Dr. Henry W. Hodgson, of Cumberland; secretary and treasurer, Dr. Charlotte B. Gardner, of Cumberland.

The Mortality of Connecticut for the Month of October 1008. During the most had been considered to the content of the Month of October 1008.

The Mortality of Connecticut for the Month of October, 1908.—During the month of October, 1908, there were reported to the Connecticut State Board of Health a total of 1,206 deaths from 164 towns. The annual death rate in 1,000 of population was 13.8 for the large towns, 14.5 for the small towns, and 13.9 for the whole State.

total of 1,200 deaths from 104 towns. The annual death rate in 1,000 of population was 13.8 for the large towns, 14.5 for the small towns, and 13.9 for the whole State.

The Third Harvey Lecture.—The third lecture in the Harvey Society course will be delivered on Saturday evening. November 21st, at 8:30 o'clock, at the New York Academy of Medicine, by Professor Graham Lusk, of the University and Bellevue Hospital Medical College. The subject of the lecture will be Metabolism in Diabetes.

ing. November 21st, at 6:30 octock, at the New Tolk Academy of Medicine, by Professor Graham Lusk, of the University and Bellevue Hospital Medical College. The subject of the lecture will be Metabolism in Diabetes.

Contagious Diseases in Chicago.—During the week ending November 7, 1908, there were reported to the Department of Health of the City of Chicago the following cases of communicable diseases: Diphtheria, 187 cases; scarlet fever, 181 cases; measles, 56 cases; chickenpox, 24-cases: pneumonia, 17 cases; typhoid fever, 45 cases; whooping cough, 14 cases; tuberculosis, 55 cases; diseases of minor importance, 28 cases; total, 607 cases.

minor importance, 28 cases; total, 607 cases.

Officers of the Ohio Valley Medical Association.—At the annual meeting of this association, which was held recently in French Lick, Ind., the following officers were elected: President, Dr. Curran Pope, of Louisville; first vice-president, Dr. A. E. Sterne, of Indianapolis: second vice-president, Dr. Earl Harlan, of Cincinnati; secretary and treasurer, Dr. Benjamin Floyd, of Evansville, Ind.

The Society of the New York Hospital.—A genito-

The Society of the New York Hospital.—A genitourinary class has been formed at the House of Relief of the New York Hospital (Hudson Street Hospital), 67 Hudson street, New York, which meets on Tuesday and Friday evenings, at 8 o'clock. All who are interested in the bacteriology of nonsyphilitic veneral sores are invited to attend these classes. For further particulars apply to

to attend these classes. For further particulars apply to Dr. Victor C. Pedersen, 45 West Ninth Street, New York. The Succession to the Surgeon Generalship of the Army.—Colonel G. H. Torney has been appointed by the president to be Surgeon General of the United States Army on the retirement of Surgeon General O'Reilly, which takes place on January 14, 1909. Colonel Torney commanded the hospital ship Relief during the Spanish War, and has been in command of the First Reserve Hospital, Manila, and the Army and Navy General Hospital, Washington, D. C. He is now in command of the hospital at the Presidio of San Francisco.

Vital Statistics of New York.—During the week end ing November 7, 1908, there were reported to the Department of Health of the City of New York 1,140 deaths from all causes, as compared with 1,248 during the corresponding period in 1907. Of the total number of deaths 568 were in Manhattan, 97 in The Bronx, 397 in Brooklyn, 60 in Queens, and 18 in Richmond. The annual death rate in 1,000 of population was 13,45 in the whole city, and in the five boroughs as follows: Manhattan, 12,92; The Bronx, 15,45; Brooklyn, 13,87; Queens, 13,46; Richmond, 12,25. The total number of deaths of children under five years of age was 303, and of these 74 were due to diarrhocal discussed. There were 121 still births. Six hundred and ninety-five marriages and 2,244 births were recorded during the work.

An Academy of Medicine in Philadelphia.—Announcement is made of the filing of the proposed charter of the Philadelphia Academy of Medicine, an intended corporation, the character and object of which is the education and mutual improvement of its members in all matters pertaining to the art of medicine, and by means of lectures, demonstrations, and the presentation of papers. to encourage research and study in all departments of medical science.

search and study in all departments of medical science.

The Health of Pittsburgh.—During the week ending November 7, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 12 cases, 0 deaths; typhoid, fever, 16 cases, 3 deaths; scarlet fever, 41 cases, 1 death; diphtheria, 17 cases, 1 death; measles, 30 cases, 0 deaths; whooping cough. 1 case, 0 deaths; pulmonary tuberculosis, 18 cases, 0 deaths. The total deaths for the week numbered 128, in an estimated population of 505,000, corresponding to an annual death rate of 11.78 in 1,000 of population.

The East Side Physicians' Association of the City of New York: A cated meating of this association

The East Side Physicians' Association of the City of New York.—A stated meeting of this association was held on Friday evening, November 20th. Dr. James T. Gwathmey demonstrated an improved gas-ether inhaler. Dr. William S. Gottheil presented models illustrating some phases of syphilis. The paper of the evening was read by Dr. Henry L. Elsner, of Syracuse, N. Y., on Serious Heart Lesions without Persisting Physical Signs. The discussion was opened by Dr. A. Jacobi, and among those who participated in the discussion were Dr. Thomas E. Satterthwaite, Dr. Charles E. Quimby, Dr. Heinrich Stern, and Dr. Robert Abrahams.

ert Abrahams.

A Public Meeting in Philadelphia in the Interest of Pure Milk.—The Public Health Committee of the Civic Club of Philadelphia held a public meeting on Monday evening, November 16th, for the purpose of discussing the question of a pure milk supply. Dr. Joseph S. Neff, Director of Public Health and Charities, presided, and addresses were delivered as follows: A City's Fight for Pure Milk, by George H. Goler, Health Commissioner of Rochester, N. Y.; The Production of Pure Milk, by Dr. Leonard Pearson, of Philadelphia; Milk as a Food for Children, by Dr. Samuel McClintock Hamill, of Philadelphia; Milk as an Economical Food, by Dr. Lawrence F. Flick, of Philadelphia.

Charitable Bequests.—By the will of Sophia Eichholz, the United Hebrew Charities, of Philadelphia, receives \$200, and the Jewish Hospital Association, of Philadelphia, receives \$100.

By the will of James McGraw, St. John's Orphan Asylum and St. Joseph's Home, Philadelphia, become contingent beneficiaries to the extent of \$1,000 each.

By the will of Charles H. Kimball the Society for the

By the will of Charles H. Kimball the Society for the Prevention of Cruelty to Animals, Philadelphia, receives \$200.

By the will of Mrs. Emma Gertrude Keep Halsey, Stony Wold Sanatorium receives \$5,000, and the Flower Hospital, New York, receives \$10,000.

Battle Organization in the Medical Department of the Navy.—The reports submitted by the surgeons of the various vessels in the Service, on the subject of organization for battle of the medical department of the United States Navy, show that there is a lack of uniformity in the organization and in the instructions given to the men regarding their stations and duties, which indicates a need for official action. The wide variation in the types of the vessels in the Service makes the formulation of definite regulations somewhat complicated, but it seems probable that steps will be taken by the Surgeon General to bring about an approximate uniformity of the plan of organization in the establishment of relief and dressing stations on vessels of similar types.

The Mortality of Chicago.—During the week ending

The Mortality of Chicago.—During the week ending November 7, 1008, there were reported to the Department of Health of the City of Chicago 530 deaths from all causes, as compared with 541 for the preceding week and 520 for the corresponding period in 1007. The annual death rate in 1,000 of population was 12,08. Of the total number of deaths, 136 were of children under five years of age. The principal causes of death were: Apoplexy. II deaths; Bright's disease, 55 deaths; bronchitis. II deaths; consumption, 76 deaths; cancer, 25 deaths; diphtheria, 21 deaths; heart disease, 40 deaths; influenza, I death; intestinal diseases, acute, 51 deaths; measles, 2 deaths; nervous diseases, 7 deaths; pneumonia, 55 deaths; scarcler fever, 8 deaths; suicide, 6 deaths; typhoid fever, 12 deaths; violence (other than suicide), 31 deaths; whooping cough, I death; all other causes, 116 deaths.

The Southern Medical Association .- At the annual meeting of this association, which was held recently in Atlanta, Ga., Dr. G. C. Savage, of Nashville, Tenn., was elected president, and the following were elected vice-presidents, one president, and the following were elected vice-presidents, one from each State in the association: Dr. J. M. Jackson, Jr., of Florida; Dr. Charles M. Murry, of Mississippi; Dr. George Dock, of Louisiana; Dr. T. A. Casey, of Alabama; Dr. J. C. Olmstead, of Georgia; and Dr. E. C. Elliott, of Tennessee. Dr. Oscar Dowling, of Shreveport, La., was unanimously reelected secretary and treasurer, and in recognition of his services for the past year was voted \$100. His report showed that the total membership of the society numbered 520. New Orleans was unanimously chosen as the place of the next annual convention, which is to be held the second Tuesday in November, 1909.

Scientific Society Meetings in Philadelphia for the Week Ending November 28, 1908:

Monday, November 23d.—Mineralological and Geological Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology

WEDNESDAY, November 25th .- Philadelphia County Medi-

WEDNESDAY, November 25th.—Finaucipina County Recal Society,
 THURSDAY, November 26th.—Pathological Society; Entomological Section, Academy of Natural Sciences; Section Meeting, Franklin Institute.
 FRIDAY, November 27th.—Philadelphia Neurological Society; Northern Medical Association; South Branch, Natural Medical Society.

Philadelphia County Medical Society.

SATURDAY, November 28th.—Samaritan Hospital Medical Society.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statistics of new cases and deaths reported for the two weeks ending November 14, 1908:

| | Nov. 7 | | Nov 14 | |
|--------------------------|--------|---------|--------|---------|
| | Cases. | Deaths. | Cases. | Deaths. |
| Tuberculosis pulmonalis | 443 | 147 | 479 | 173 |
| Diphtheria | 201 | 16 | 337 | 23 |
| Measles | 137 | 6 | 180 | 3 |
| Scarlet fever | I 43 | 0 | 215 | 7 |
| Smallpox | | | | |
| Varicella | OI | | 96 | |
| Typhoid feer | 5.3 | 1.2 | 78 | 1.5 |
| Whooring cough | 9 | .3 | 18 | 2 |
| Cerebrospinal meningitis | 5 | 2 | 6 | 2 |
| | | | | |
| Totals | 1,172 | 192 | 1.409 | 2.2 * |

The Medical Society of the County of New York .-The one hundred and third annual meeting of this society will be held on Monday evening, November 23d, at 8:15 o'clock, in Hosack Hall, New York Academy of Medicine. The programme for the scientific session will consist of a "symposium" on tuberculosis, which has been arranged as a part of the introductory exercises attending the opening in New York of the exhibit of the International Congress on Tuberculosis, held recently in Washington, D. C. The following papers will be read: The Lessons of the Recent International Tuberculosis Congress, by Dr. Woods Hutchinson; The Incidence of Tuberculous Bacilli in New York son; The Incidence of Tuberculous Bacilli in New York City Milk, with a Study of its Effects on a Series of Children, by Dr. Alfred F. Hess; discussed by Dr. Henry Koplik, and Dr. Rowland C. Freeman; The Relative Importance of Human and Bovine Types of Tubercle Bacilli in Human Infection, by Dr. William H. Park; The Methods Employed to Differentiate the Different Varieties of Tubercle Bacilli, by Dr. W. H. Woglom. A general discussion will follow will follow.

The Health of Philadelphia.- During the week ending October 31, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 36 cases, 4 deaths; scarlet fever, 54 cases, 6 deaths; chickenpox, 33 cases, 0 deaths; diphtheria, II2 cases, II deaths; cerebrospinal meningitis, I case, death; measles, 33 cases, 3 deaths; whooping cough, 6 cases, 1 death; tuberculosis of the lungs, 138 cases, 41 deaths: pneumonia, 60 cases, 40 deaths; erysipelas, 4 cases o deaths; imumps, 6 cases, 40 deaths; erysipelas, 4 cases, 10 deaths; imumps, 6 cases, 10 deaths; case, 11 death; diarrhœa and enteritis, under two years of age, 16 cases, 26 deaths. The following deaths were reported from other transmissible diseases; Tuberculosis, other than tuberculosis of the lungs, 1 death. The total deaths numbered 405 in an estimated population of 1,532,738, corretion. The total infant mortality was 89; under one year of age, 75; between one and two years of age, 14. There were 30 still births; 15 males, and 15 females. The total precipitation was 1.61 inches.

Society Meetings for the Coming Week:

Monday, November 23d .- Medical Society of the County

TUESDAY, November 24th.—New York Dermatological Society; New York Otological Society; New York Medical Union; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Obstetrics and Gynæcology)

Wednesday, November 25th.—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Surgical Society.

THURSDAY, November 26th .- New York Academy of Medicine (Section in Obstetrics and Gynæcology); Brook-lyn Pathological Society; Hospital Graduates' Club, New York; New York Celtic Society; Brooklyn So-

Friday, November 27th.—New York Clinical Society; New York Society of German Physicians; Academy of Pathological Science, New York.

SATURDAY, November 28th.—West End Medical Society, New York; New York Medical and Surgical Society; Harvard Medical Society, New York; Lenox Medical and Surgical Society, New York.

The Howard Hospital and Infirmary for Incurables, of Philadelphia.—The forty-fourth annual report of the Board of Managers of the Howard Hospital and Infirmary for Incurables showed that 779 patients were treated during the year; of these 603 were discharged cured; 71 were discharged improved; 25 were discharged unimproved; 22 were discharged not operated upon; and 45 died. The death rate was 5.77 per cent. In the out patient department 7.973 patients were treated; of these 5,212 were white, and 2,761 were colored; 2,438 were treated in the department of general surgery and orthopædics, 1,686 in the department of general medicine, 767 in the department of the diseases of women; 918 in the department of the diseases of women; 918 in the department of the diseases of women; 918 in the department of the diseases of women; 918 in the department of the diseases of children, 286 in the department of diseases of the mind and the nervous system, 679 in the department of the diseases of the eye, 656 in the department of the diseases of the nose, and 543 in the department of the diseases of the skin. There were 2,278 accident cases. During the year a legacy of \$370 was received from the estate of Elon Dunbar, and one of \$375 from the residuary estate of George S. perper. The report of the secretary of the board of managers shows that the cost of maintenance of each patient was \$2.00 a day; the cost of each out patient was 345 cents a day. The treasurer's report showed a deficit of \$2.187.21.

Personal.—Dr. Thomas E. Satterthweite, of New York, had conferred upon him the degree of doctor of laws by the University of Maryland, on the occasion of the celebration of the one hundred and nineteenth anniversary of the opening of St. John's College, Annapolis, which embodies the departments of science and arts of the uni-

Dr. Benjamin Franklin Stahl has been appointed medical director of St. Agnes's Hospital.

Dr. Henry J. Summers has resigned as pathologist to the Hospital for the Insane at Norristown, Pa.

Dr. Amy J. Rule has been elected an assistant physician to the Hospital for the Insane at Norristown, Pa

Dr. James S. Mosher, of Williamsport, Pa., and Dr. Smith De Muth, of Pittsburgh, Pa., are registered at the Philadelphia Polyclinic and College for Graduates in Medi-

Dr. Cyrus Field, of New York, has accepted the chair of pathology and bacteriology in the reorganized medical school of the University of Louisville.

Dr. De Forest Willard, professor of orthopædic surgery at the University of Pennsylvania, has been appointed consulting orthopædic surgeon at the Municipal Hospital, Phil-

Dr. William Warren Potter, of Buffalo, has been elected president of the New York State Board of Medical Examiners, and Dr. William S. Searle, of Brooklyn, vice-presi-

Dr. Guy G. Fernald, of Boston, has been appointed resident physician of the Massachusetts Reformatory at Con

Sir Jagadis Chandra Bose, M. D., Sc., of Calcutta, India, delivered a lecture recently on the Plant as a Living Machine at the Biological Club of the Massachusetts Institute of Technology

The College of Physicians of Philadelphia.-The reg ular monthly meeting of the Section in Otology and Laryng ology was held on Wednesday evening, November 18th. Di Ralph Butler reported a case of mucocele of the frontal sinus and exhibited the patient. Dr. Emma E. Musson sinus and exhibited the patient. Dr. Emima E. Musson read, by invitation, a paper on Labyrinthine Deafness. Dr. Arthur A. Bliss read a paper entitled Some Notes on Furunculosis of the External Auditory Canal. Dr. G. Hudson-Makuen reported'a case of sudden deafness in a child of nine years, and made special reference to its effect upon the speech.

The Section in Ophthalmology held a stated meeting on Thursday evening, November 19th. Dr. B. Alexander Randall read a paper entitled Again a Word as to the Weiss Reflex "Bogenstreife" in its Relation to Progressive Myopia. Dr. Burton Chance reported a case showing the effective states of the second of the se opia. Dr. Burton Chance reported a case showing the effects of obstetric injury of the cornea observed in an adult. Dr. Howard F. Hansell reported a case of membranous conjunctivitis with systemic complications, and exhibited a patient with a growth in the vitreous, probably arising in the optic nerve. Dr. J. Norman Risley gave the histories of two cases of keratitis with abnormal nasal conditions as contributing actiological factors. Dr. George S. Crampton reported a case of probable sarcoma of the ciliary body, exhibiting the patient, and gave the history of a case of marked ectasia of the sclerotic simulating tumor, showing specimens.

Meetings of Sections of the New York Academy of Medicine.—A meeting of the Section in Ophthalmology was held on Monday evening, November 16th. The paper of the evening was read by Dr. Percy Fridenberg on Vascular Disease of the Retina as a Factor in Embolism of the Central Artery. Dr. Alexander Duane gave a demonstration of charts indicating fallacies in our present ideas regarding the accommodation.

regarding the accommodation.

A meeting of the Section in Medicine was held on Tuesday evening, November 17th. Dr. W. N. Berkeley presented a patient with syringomyelia. Dr. Warren Coleman reported a case of brain tumor. Dr. W. E. Boyce read a paper describing a new treatment for chronic arthritis. Dr. David Bovaird read a paper on the Nauheim Treat-

The Section in Genitourinary Surgery held a meeting on Wednesday evening, November 18th. The programme consisted of the reports of cases and the presentation of

on Wednesday evening, November 18th. The programme consisted of the reports of cases and the presentation of specimens, instruments, and patients.

The Section in Orthopadic Surgery held a general clinical meeting on Friday evening, November 20. Cases were presented as follows: a, Genu Recurratum following Transplantation of Hamstrings, by Dr. Henry Ling Taylor; b, Hæmatoma of Thigh, by Dr. Virgil P, Gibney; c, Sarcoma of Radius successfully treated by the Mixed Toxines of Erysipelas and Bacillus Prodigiosus, by Dr. William B. Coley; d, Two Cases illustrating Result in Ambulatory Treatment of Rigid Weak Foot, by Dr. Arthur H. Cilley; c, Case of Fracture of Neck of Fenur, by Dr. Arthur H. Cilley; f, Case Simulating Psoas Abscess, by Dr. Charles H. Jaeger; g, Case of Coxa Vara, by Dr. Royal Whitman; h, Case of Stitt's Disease, by Dr. Walter W. Strang; t, Two Cases of Progressive Muscular Atrophy of an Irregular Type, by Dr. T. Halsted Myers; j, Case of Volkmann's Lodemic Paralysis, by Dr. Reginald H. Sayre; k, Case of Unilateral Congenital Dislocation of Hip, Reduction, Subsequent Hypertrophy of Bones of Leg, by Dr. Reginald H. Sayre, A general discussion followed.

The Section in Larvygology and Rhinology will meet on

The Section in Laryngology and Rhinology will meet on Wednesday evening. November 25th, at 8:15 o'clock. Dr. Harmon Smith will present a patient with laryngeal carcinoma, with laryngeatcomy after twelve years' observation. Dr. Hanau W. Loeb, of St. Louis, Mo., will read a paper entitled A Study of the Anatomical Relations of the Optic Nerve to the Accessory Sinuses of the Nose, and will present specimens showing the relations. sent specimens showing the relations.

sent specimens showing the relations.

A meeting of the Section in Obstetrics and Gynæcology will be held no Friday evening, November 27th. Dr. Samuel M. Brickner will present a patient with an unusual case of vesico-vaginal fistula, and Dr. S. W. Bandler will present patients showing resection for carcinoma of the cæcum, ovarian sarcoma in a young girl, and carcinoma of the vagina. Dr. Robert T. Frank will read a paper entitled An Analysis of Eighty Consecutive Cases of Ectopic Gestation, which will be followed by a general discussion of the immediate genus the deferred operation in extension in extension. of the immediate versus the deferred operation in ectopic gestation.

Cancer of the Stomach. By Christopher Graham. An Experimental Study of the Conjunctival Tuberculin Test in Guinea Pigs Infected with Human, Bovine, or Avian Tubercle Bacilli. Specificity. Reaction. Unity for the Group. Lack of Sensitization.

By Frederick T. Lord.

Bursitis Subacromialis, or Periarthritis of the Shoulder Joint. (Subdeltoid Bursitis.) (To be continued). By ERNEST AMORY CODMAN.

2. Experimental Study of the Conjunctival Tuberculin Test in Guinea Pigs.—Lord finds that nontuberculous guinea pigs fail to respond to the conjunctival test with old tuberculin of the ordinary concentration or with stronger preparations in which the evaporation of the culture is carried to one twentieth or even one thirtieth of its volume. Attempts at sensitization with old tuberculin by various means have failed to elicit a response in sound animals. After subcutaneous and intraperitoneal infection of guinea pigs with human, bovine, or avian tubercle bacilli, positive conjunctival tests with undiluted old tuberculin may usually be obtained after a variable interval. The period of incubation commonly terminates in from two to four weeks. The reaction may begin as early as two hours after the insufflation of tuberculin into the conjunctival sac, is usually at its height in seven to eight hours, and may have subsided in twenty to twenty-four hours. The reaction is not invariably present, and is, therefore, somewhat unreliable for the detection of tuberculosis in guinea pigs. In general, however, it occurs in a large proportion of the tests performed during the positive period, and when it occurs appears to be specific for tuberculosis of the human, bovine, or avian type. The reaction, although specific for the group, appears not to be distinguished between the different types of infection. Animals infected with human, bovine, or avian tubercle bacilli respond as well to the corresponding or different tuberculins. Unheated cultures of tubercle bacilli, concentrated in vacuo without heat and filtered through a porcelain filter, cause reactions in infected animals, but, like old tuberculin, are not distinctive in their action. The emulsion of tubercle bacilli and unconcentrated filtrates fail to elicit a response. This reaction unity in guinea pigs infected with human, bovine, or avian tubercle bacilli is confirmatory of the close relationship between these different strains of tubercle bacilli. The absence of reactions in nontuberculous guinea pigs and the positive response in tuberculous animals is confirmatory of the specificity for tuberculosis of reactions in man. The failure to produce reactions in nontuberculous animals after attempted sensitizations with old tuberculin suggests that reactions with this substance after repetition in man are not likely to occur in the nontuberculous.

Viscosity of the Blood.-McCaskey states that the viscosity of the blood is an important physical property dependent on both the corpuscles and the plasma which furnishes a considerable part of the peripheral resistance to the circulation of the blood. It undergoes fluctuations as a result of physiological changes connected with food, drink, exercise, etc. Under pathological conditions, the changes are much greater and the viscosity may be so much increased, as for instance, when the blood is charged with carbon dioxide, that the heart will be embarrassed in overcoming it. The viscosity is actually low in the large majority of cases of chronic Bright's disease owing to existing hydræmia, but there is probably an earlier stage with high viscosity. seems probable that an increased peripheral resistance in the circulation of the blood, due, in part, to increased viscosity, is at least one of the factors in the production of the cardiac hypertrophy of Bright's disease. Venesection greatly lowers the viscosity by withdrawing its solids and attracting the fluids from the surrounding tissues. Alcohol introduced into the circulation greatly increases viscosity, and in this way interferes with the peripheral circulation and burdens the heart. The approximate determination of the viscosity of the blood as a routine clinical procedure is desirable in nutritional and toxic disorders, and should be made by a method rapid and simple enough to be practicable for routine use. Individual diseases do not change viscosity in any characteristic way except as they incidentally modify the blood. The determination of viscosity should be made promptly before the corpuscles have time The use of hirudin, if it leads to considto settle. erable delay, is therefore objectionable unless the homogeneous mixture of plasma and corpuscles is again reproduced. The viscosity of the blood is not altogether dependent on its specific gravity, for in fevers the former may be high and the latter very low.

2. Bloodvessel Surgery.—Guthrie says that it has been known for a very long time that the activities of the tissues of the body may be profoundly influenced by alterations of the circulation. This consists of decreasing or increasing the blood to a part. Decreasing the circulation brings about the condition termed anæmia; increasing the circulation produces "hyperæmia." Tying an artery will produce anæmia; increasing the arterial flow to a part as by causing a local dilatation produces active hyperæmia, while by hindering the venous return passive hyperæmia will be produced. The magnitude of the changes observed in normal tissues after production of a localized hyperæmia is in direct production of a localized hyperæmia is in direct pro-

portion to the degree of hyperæmia. By reversing the circulation in the peripheral end of one of the external jugular veins by anastomosing it with the central end of one of the common carotid arteries, no doubt a degree of passive hyperæmia of the head If, however, the circulation is simis produced. ilarly altered in a vein having a more "terminal" character, as in the inferior thyreoid vein, the results are striking. This operation produces what may be termed a double hyperæmia, as by eliminating the vein as a channel for return of venous blood, the ratio of venous to arterial cross sectional area of the gland is decreased; therefore, passive But since arterial blood is hyperæmia results. forced into the gland through the vein, the proportion of arterial area to venous areas is further increased, and active hyperæmia is also produced. Such an operation produces a maximum hyperæmia, and the results on both normal and pathological glands are very marked. In both cases a rapid transudation is seen to take place from the bloodvessels, the glands becoming markedly ædematous even in a few minutes. The swelling increases for about forty-eight hours, by which time, in pathological glands, it may reach enormous proportions. At the end of this period it begins to subside, so that at the end of about twelve days the gland is about the same size as at the time of operation. In the case of enlarged pathological glands, from this time onward there is a continuation of decrease in size so that at the end of three weeks or a month the gland may not greatly exceed a normal gland in size. The chief clinical distinction in the reaction thus set up in a normal and pathological gland is of degree. Also, it seems that the normal gland does not decrease to below, its size at the time of operation. Ligation of the thyreoid veins in pathological glands is followed by a similar train of clinical phenomena, the difference again being one of degree.

Transplantation of Bloodvessels. — Carrel remarks that it is proved that the remote results of the transplantation of fresh vessels can be perfect, and that arteries, kept for several days or weeks outside of the body, can be transplanted successfully, and that after more than one year the results remain excellent. It has been shown, also, for the first time, that transplanted kidneys functionate, that an animal, having undergone a double nephrectomy and the transplantation of both kidneys from another animal, can live normally for a few weeks, and that an animal which has undergone a double nephrectomy and the graft of one of his own kidneys can recover completely and live in perfect health for eight months, at least. Finally, it has been demonstrated that a leg extirpated from a dog and substituted for the corresponding leg of another dog, heals normally.

6. Infantile Paralysis.—Lovett and Lucas report the analysis of 635 consecutive, unselected cases of infantile paralysis, seen at the out patient department of the Children's Hospital at Boston during the year 1907. The authors reach the following practical conclusions: It is important to remove deformity by a preliminary operation when it is present to any considerable degree and not to correct the deformity and perform the tendon transfer at one

operation. The operation should not be performed on very young children. Periosteal implantation yields better results than when tendons are united to tendons. Simple operations are more satisfactory than complicated ones. It is not advisable to turn sharp corners with transferred muscles, but to secure as straight a line as possible of muscular pull from origin to insertion. The substitution of small muscles for large ones is likely to be unsatisfactory, e. g., one of the peroneal muscles is rarely a satisfactory substitute for the gastrocnemius. Tendons must be inserted on the stretch, and the foot maintained for some weeks in a position of overcorrection. The use of silk tendons has proved practicable and satisfactory. The after treatment is as important as the operation itself, if a successful result is to be obtained. The method followed at the Children's Hospital has been as follows: The plaster put on at the operation is worn for six weeks. It is then split, removed for massage, and reapplied. About two or three months after the operation a brace is applied which shall support the foot in a position to relieve strain on the transferred tendon, and muscle training is begun. Walking is allowed from three to six months after operation in this brace, when the tendon seems to possess enough power to warrant it, and the brace is discontinued when circumstances allow it. Infantile paralysis is a less formidable affection than is generally believed, partial paralysis is common, disused and stretched muscles appear to be paralyzed, but possess a possibility of function. In addition to mechanical treatment, an attempt should be made by massage, electricity, and especially by muscle training to wake to activity the remaining cells in partly destroyed groups and thus to secure muscles which perform function. After tendon transfer, the development by muscle training of the transferred tendons is essential to good results, and without this the percentage of failure will be large.

9. Infant Feeding.—Allen describes his method of calculation, and says of his plan that it is more comprehensive than all other systems. There is absolute control of not only energy and proteid, but also of the ratio between these two. Other plans control the energy alone or the proteid and energy, as when his proteid quotient is used, but no other plan suggested controls the proteid, energy, and ratio, enabling one to know at any time just what and how much he is giving. It is easily changed to meet changing conditions of weight, age, etc. It is simple, and the calculations are extremely easy. Taking the three numbers representing the weight, the proteid quotient, and the ratio, it is seen that one fourth of the product of the first and second gives the amount of milk for the day; the product of the second and third gives the energy in sugar units, and the product of the first, second, and third-lessened by the ratio of the food used-gives the sugar in hundredths of an ounce which must be added. The numbers are all small and easily handled. The operations are reduced to one, that of multiplication, and the fractions, whether vulgar or decimals, are simple and in most cases can be handled without even the use of a pencil.

MEDICAL RECORD.

November 14, 1908.

I. Observations with the Rogers-Torrey Antigonococcic Serum, By George Knowles Swinburne.
2. Röntgen Ray Flashes or Intermittent X Rays,

Röntgen Ray Flashes or Intermittent X Rays,
By Finley R. Cook.

Synovitis of the Knee Joint as a Late Manifestation of
Acquired Syphilis. Report of a Case,
By ISAAC LEVIN.

7. The Action and Dosage of Phenolphthalein,
By Warren Philo Elmer.

1. Rogers-Torrey Antigonococcic Serum. — Swinburne has treated since October, 1907, sixtynine patients with the Torrey antigonococcic serum, forty-one were dispensary patients and twenty-eight were patients in private practice. The cases were as follows: Chronic relapsing epididymitis, fourteen; acute epididymitis, early stages, twenty-seven; muscular rheumatism, without joint involvement, fourteen; muscular rheumatism, with one or more joints involved, ten; purely joint cases, five; chronic gonorrhœa of kidney, two: involvement of tube and ovary, one; persistent presence of gonococcus in urethral discharge, two; acute prostatitis, one; acute vesiculitis, one; threatening epididymitis, one; rheumatism and epididymitis, one. In almost all the patients with relapsing epididymitis, ten of which were dispensary cases, there was marked improvement. The striking relief noted was in the diminution or quick cessation of the pain. These cases are more or less unsatisfactory, because the patients have been difficult to follow. Some go back to work too soon and only return because of further relapse, and as they have a variety of conditions in the anterior or posterior urethra, all of which require more or less prolonged treatment, in most of them the serum alone is not sufficient to prevent a relapse-still in all of them there was marked relief after the second injection. Dr. Swinburne relies upon the serum as a valuable aid in the treatment in epididymitis.

2. Röntgen Ray Flashes or Intermittent X Rays.-Cook remarks that a simple and prolonged stimulation can be obtained only by an intermittent bombardment of tissue cells. An intermittent bombardment not only eliminates the dangers arising from x ray treatment, but enables us to increase the amperage, and hence to obtain a far greater degree of stimulation. With flashes we do not use any protective measures, and inasmuch as the general action is just as important as the local, if not more so, the whole body is included in the x ray field, the rays of maximum intensity being focused on the local area under treatment. For the same reason we use a tube approaching hardness. The effort to secure pure stimulation by the customary continuous method was against the established principles of stimulation and must be attended with danger, as experience has amply shown. In all conditions where x rays have been useful it has been due to their general as well as their local action. The general action is shown by the inevitable improvement in general metabolism

with a local regenerative action in an area of localized degeneration. The most striking proof of the systemic action is obtained through sphygmomanometric observations. Sedation is obtained by a mild and continuous bombardment. This suggests low amperage with tube at a distance measured by feet rather than by inches. Tension is lowered and tendency to sleep induced. This is an x ray bath. The whole body is included in the x ray field. Escharization is obtained by a powerful and continuous bombardment. Maximum amperage, minimum distance, maximum time of exposure. All normal tissues should be thoroughly protected with heavy sheets of lead with an opening exactly corresponding to the parts to be destroyed. Irritation is obtained by a moderate and continuous bombardment, prolonging the time of exposure or by repeated exposures. It comes through overstimulation, which is the primary action. Like all irritants, it tends to induce a fibrosis, obliterating endarteritis, and culminates in atrophy. It should never be used on normal tissues, and when used on local morbid cells the surrounding normal cells should be carefully protected by sheets of lead foil. The author comes to the conclusion that the evolution of Röntgen ray flashes not only eliminates the danger of x ray treatment, but that this method will extend the field of its influence, that its use in the eve will prove to be its most valuable therapeutic application, and there is a strong probability that if employed skilfully in the early and acute stages of many heretofore incurable diseases of the eye, it may prove to be a valuable preventive of blindness.

3. Medical Treatment of Inflammations of the Biliary Tract.-Berkeley reminds us that drugs so far as we know have not the least demonstrable solvent effect upon gallstones, any more than upon stones in the kidney and urinary bladder. We may, however, select among a large number of medicines which have more or less effect in increasing the fluidity of the bile, and apparently stimulating its secretion. Any of the saline purgatives will act in this way to some extent. Sodium phosphate in dilute aqueous solution before breakfast has long been approved. The alkaline mineral waters have this additional advantage, that they are in extremely dilute solution, and the patient in taking his medicine is compelled to take a large amount of water at the same time. Sodium glycocholate and taurocholate have been experimentally and clinically proved to be direct and very valuable cholagogues. Their nauseous taste, long a serious objection, has been latterly removed by dexterous admixtures in several of the new proprietary preparations, and they may be given as required. It is stated of all these drugs that they only put into a healthy condition an inflamed biliary mucosa, enabling the gallbladder to take care of the stones it already contains, facilitating the discharge of those already actually lodged in the ducts, and preventing the formation of new stones. All these remedies, furthermore, reduce intestinal putrefaction, move the bowels more freely, promote digestion, and by improving the patient's general condition, increase his resisting power all along the line. Antifermentative drugs, like salol, are often helpful. Patients will ultimately find out for themselves what laxative

remedy suits them best. By some means or other it will be absolutely necessary to keep the bowels open.

Copious enemata are good.

7. Phenolphthalein.—Elmer states that phenolphthalein probably belongs to the class of intestinal irritants, but its action seems to be accompanied by less discomfort than the majority of cathartics of this class. It is nontoxic, at least in doses up to 25 or 30 grains. It is extremely stable, very little if any being broken down in passing through the body. A little is absorbed, but is excreted by the kidneys as such. The average dose may be placed at from one to five grains, best given in the powdered form, either at night or in divided doses after meals. In cases of overacidity it can be advantageously combined with an antacid powder.

 14. Discussion on Causation and Treatment of Scurvy,
 Especially Infantile Scurvy,
- Introduced by SIR A. WRIGHT. 15. On Interstitial Keratitis, with Especial Reference to
- Pathogenesis and Treatment, By S. STEPHENSON.
- 2. Purin Free Diet.—Bryce states that, while the advantages to be derived from the adoption of a purin free diet are sometimes very notable, yet in some cases the results are not so favorable. In all chronic cases of disease in which the ordinary methods of treatment yield no good result, the writer cuts off all xanthin-and purin-containing articles of diet which are at the same time nonnutritious, and this includes tea, coffee, cacao, meat soups, beef teas, and gravies. The first three contain methyl purins, which, though they add no uric acid to the excretions, increase very largely the total urinary purin content. Personal idiosyncrasy has much to do with the diverse results reported, and in the writer's opinion this is ultimately bound up with the metabolic activity of the cells, and especially the cells of the mucous membrane, to withstand the onslaught of irritants such as purin compounds. Small quanti-

ties of purin are almost invariably well borne, and only in isolated cases are larger doses not tolerated. The ability to tolerate purins is markedly influenced by disease-for example, neurasthenia, so called, and kidney ailments where the integrity of the cells of the convoluted tubules is doubtful, yet a man in perfect health with a so called gouty tendency may tolerate them badly because they act as irritants to the mucous membrane of the hepatic ducts, and produce

hepatic insufficiency. 6. Cerebrospinal Meningitis.—Holt's paper is based on a series of 442 cases of cerebrospinal meningitis treated with the serum of Flexner and Jobling. The general case fatality of the disease, in different places and at different times, varies from fifty to eighty per cent. Of the 442 cases here reported on, 295 patients recovered—giving a case fatality of 33.3 per cent. But if the moribund cases, forty patients in number, in whom death occurred within twenty-four hours, are eliminated, the case fatality is reduced to exactly twenty-five per cent. The serum is obtained from horses which have been immunized by injections derived from many strains of the men-ingococcus. Between four and five months are required before the serum is strong enough to use. The serum acts chiefly on the meningococci, diminishing their viability and increasing their capability for phagocytosis. By its effect upon the microorganisms it arrests the inflammatory process. To accomplish this result the serum must be brought directly into contact with these organisms and in a certain degree of concentration. This explains why the serum is practically without effect when given subcutaneously, and also why as much cerebrospinal fluid as possible should be withdrawn before the injection is made. While essentially a bacteriolytic serum, it must possess some antitoxic value as well, for in no other way can be explained the striking rapidity with which the subjective symptoms often improve after injection. From being one of the diseases most to be dreaded, both on acount of its high mortality and its sequelæ, often worse than death, it seems probable that cerebrospinal meningitis will become, like diphtheria, one most certainly controlled by treatment.-Macgregor has studied the development of specific agglutinating bodies and opsonins in the sera of cerebrospinal meningitis patients, and has correlated these immunity phenomena with the general toxic manifestations and the pathological anatomy in the various phases of the disease. His conclusions are as follows: 1. In very acute infections, where toxemic symptoms are severe and death rapidly ensues, there is an entire absence of agglu-tinins from the blood. These cases form the chief epidemic type. 2. On the other hand, in cases which are chronic from the outset the blood contains no agglutinins. These cases may have prolonged pyrexial courses. 3. The degree of agglutinating power which is developed in any given case depends on the initial features of the case, being proportional to (a) acuteness of onset, (b) duration of primary toxæmia, and (c) degree of reaction. 4. Agglutinins are produced only in response to the early toxic phenomena; they appear to be independent of the subsequent course of the case. 5. In a few acute cases, most of which recover, the agglutinins are absent or very feeble, hence they are of little value in the di-

agnosis of such short, often indefinite, cases, 6. The highest opsonic indices occur mostly in those cases of acute initial symptoms of not too short duration which also, as has been noted, possess most marked agglutinating power. Where agglutinating power has been low the index has usually been low. 7. Accordingly, a high index is a sign of a forcible reaction to a fairly severe infection and is of no prognostic value, as patients with low index may recover and patients with a high index have died. 8. The indices tend to be highest during the second and third weeks of illness in an average case. o. The degree of immunity after recovery, as measured by the opsonic index, is very variable. There may be an active opsonin in the blood for many weeks after resolution, or it may occasionally disappear comparatively rapidly. 10. It is scarcely worth while to refer to its diagnostic value. In a typical severe case the opsonic films are no doubt extremely characteristic, but the isolation of the meningococcus from the cerebrospinal fluid is the most valuable and uniform diagnostic method.

By R. McCarrison.

A Contribution to the Study of the Administration of Tuberculin in Pulmonary Tuberculosis,

By A. Latham and A. C. Inman.

4. Some Unusual Sequelæ of Convulsive Seizures in Childhood,

By F. J. Poynton.

 Lupus Erythematosus.—MacLeod divides lupus erythematosus into two main varieties: (a) The discoid or circumscribed type, which is chronic in its evolution and course; and (b) the disseminated and more or less acute type. Of these the discoid type is by far the more common. Among the main varieties of discoid lesion are the following: I. A well defined lesion with a raised border and an adherent scale in the centre. 2. A nonscaly type in which the epidermis is not affected, the lesions approximating either those of multiform toxic erythemata or lupus vulgaris. 3. A variety with telangiectases over the lesions. In the second main type, the acute disseminated, the lesions develop much more rapidly and the area involved is more extensive. The lesions appear first as vivid erythematous patches about the face, which become covered with adherent scales, spread quickly, and coalesce to involve large areas. These cases are sometimes mistaken for erysipelas, especially when fever is present. All the lesions of both varieties possess two characteristics—that of persistent erythema and that of being succeeded by more or less atrophic scarring. Many authorities hold that lupus erythematosus is a form of tuberculosis, differing from lupus vulgaris in not being the result of the reaction of the skin to the tubercle bacillus in situ. They maintain that the lesions are due to the presence of the tuberculous toxine in the skin which has reached there via the blood stream and has been produced by bacilli situated in some remote tuberculous focus, that lupus erythematosus is a "toxituberculide.' But the writer thinks that at the present time there does not seem to be sufficient evidence, clinical, histological, or bacteriological, to prove that it is a tu-

berculous manifestation, nor is there conclusive proof that in those cases in which it occurs in tuberculous subjects the tuberculous toxine is the direct cause of it. A study of the condition in its many aspects suggests that it is not in the true sense a pathological entity due to one specific cause, but is rather a morbid condition of the type of an ervthema, which is persistent in character and tends to be succeeded by atrophy, and which may be brought about by a variety of causes in a predisposed individual. As predisposing causes may be cited: (a) hereditary weakness; (b) enfeebled states of health resulting from any general morbid condition, of which tuberculosis and rheumatism are probably examples; (c) a weak peripheral circulation and various circulatory disturbances arising from anæmia, heart disease, etc.; and (d) a delicate condition of the bloodvessels in the situations usually affected, owing to anatomical reasons. Direct causes may be divided into: Local, such as cold, sudden temperature changes, sunlight, traumatism, mosquito bites, or microbic infection; and toxines reaching the skin via the blood stream, such as toxines resulting from imperfect metabolism in the intestinal tract or from a defective state of the kidneys, liver, or other organ. Lupus erythematosus has long been recognized as one of the most intractable of skin affections. Local treatment has afforded the best results so far. Internally quinine and salicin have been recommended. The first step in local treatment is to remove the adherent scales and to prevent their reforming. This can be done with green soap spirit or salicylic acid ointment. The next indication is the drying of the lesions, which can be done by bland powders, by lotions containing an insoluble deposit, and by pastes containing equal parts of powder and grease. A further indication is the reduction of the hyperæmia and vascular dilatation, for which ichthyol ointment may be employed to advantage. The Finsen light sometimes gives good results, but the x rays are contraindicated.

2. Endemic Cretinism. — McCarrison studied endemic cretinism in India and has reached the following conclusions: I. The degree to which cretinism is associated with goître is determined by the age of the endemic and varies directly with the extent to which the latter disease prevails among the adult population. 2. Cretinism is rarely if ever due to the development of a goitre in the individual. The thyreoid enlargement is, or may be, an effect; it is not the cause of the disease. 3. Defective thyreoid function in the mother is the essential factor in the production of cretinism. 4. Cretinism is due to the action of toxic agents, notably that of endemic goitre on the developing thyreoid of the unborn child. 5. The thyreoid defect is congenital, but it may remain latent pending its manifestation through the impulse of some accidental circumstance. 6. The defect in cretinism is one of the whole thyreoid mechanism, of the parathyreoids as well as of the thyreoid gland. The diversity of symptoms is due to the extent to which the defect bears upon the whole or part of that mechanism,

3. Tuberculin in Pulmonary Tuberculosis.— Latham and Inman sum up their conclusions as follows: 1. Tuberculin may be given with effect by the mouth or rectum, or subcutaneously. The dosage

is dissimilar, but animal experiments, opsonic curves, and temperature charts show that the effects produced are the same. 2. The administration of tuberculin meets with little, if any, success so long as successive autoinoculations spontaneously occur and cannot be limited by the means at our command. Absolute rest is the most efficient means for limiting autoinoculation. 3. The administration of tuberculin may be adequately controlled in a large percentage of cases of pulmonary tuberculosis by a careful daily observation of the temperature and clinical condition of the patient. 4. In cases of difficulty valuable information may often be obtained from an examination of the opsonic index. 5. The German method of the routine administration of tuberculin by gradually increasing doses at stated intervals is not to be recommended. It is only satisfactory in a very limited class of cases, and even then may not lead to the best results. 6. Tuberculin is a dangerous drug and its administration requires considerable experience. It is capable, when given improperly, of producing disastrous and even fatal results.

 By P. Desfosses.
- 1. Continuous Partial Epilepsy.-Schmiergeld discusses the symptomatology, ætiology, pathogeny, pathology, development, prognosis, diagnosis, and treatment of this disease, which was first described in 1894 by Kojewnikoff, a Russian physician. Only sixteen cases have been reported, all in Russia. The essential characteristic of the disease is the coexistence in the same patient of attacks of epilepsy and partial convulsions persisting during the intervals between the attacks. In eleven of the sixteen cases the patients were women. It was ascribed in six to infectious diseases, in two to syphilis, in three to alcoholism, and in four to traumatism. Little is known of the pathology, as no autopsy has as yet been secured, but Osokine removed a bit of the cortex during an operation on one patient and found very distinct changes therein. The disease develops very slowly, and the prognosis is not good. It is liable to be confounded with paralysis agitans, chorea, tics, Jacksonian epilepsy, in which the paroxysms succeed each other without intermission, and finally epilepsy complicated by chorea. Treatment with the bromides gave the best medical results, according to one author; another preferred trinitrine. Surgical treatment resulted in a diminution of the involuntary contractions, which lasted in one case five and in another four years,
- 2. Serious Icterus of Secondary Syphilis.— Sezary reports a case of this nature that resulted fatally. He gives its characteristics as an insidious appearance of icterus without apparent cause in a voung woman who presented the stigmata of sec-

ondary syphilis, the absence of preexistent digestive troubles, the absence of fever, and later the presence of a subnormal temperature, the absence of brachycardia, the nocturnal malaise which disappeared during the day, and finally the sudden development of this seemingly benign icterus into a malignant form, The pathology and microbiology are dwelt upon at length.

10. Charitable Institutions for Mothers and Infants and Their Financial Support, By W. HANAUER.

11. Ovulation and Pregnancy in Forensic Psychiatry,

By Hugo Marx.

I. The Protection of the Stomach against Self Digestion.—Katzenstein says that living, well nourished tissue may be digested in its own stomach, that the stomach and duodenum are able to resist the action of this juice only in consequence of a process of adaptation, that this property is not dependent on the life of the cells, but that even the dead wall of the stomach exhibits a power of resistance to digestion, and that the continued existence of an ulcus ventriculi is probably dependent on a diminution of the antipepsin in the wall of the stomach and the blood. Therapeusis through administration of antipepsin is therefore indicated in ulcer of the stomach.

Blood Conditions in Exophthalmic Goître and Thyreoidismus.-Caro concludes: 1, The well marked cases of exophthalmic goitre show a great reduction of polynuclear leucocytes, as great

as fifty per cent., and a great increase of mononucleated white corpuscles (lymphocytes in the narrow sense) up to fifty per cent. The small lymphocytes predominate among the mononucleated white blood corpuscles. 2, The increase of the entire number of mononucleated white corpuscles is found, though not in so high a degree, in thyreoidism. This can be of value in cases that are difficult to diagnosticate. 3, The proportion in which the lymphocytes in the narrow sense and the large mononucleated cells take part in the increase of the entire number of mononucleated white blood corpuscles varies in different cases. In the cases of simple thyreoidismus an increase of the large cells seems to predominate, in the severer cases of exophthalmic goître the small lymphocytes. The fewer the clinical symptoms of thyreoidism that are present the more nearly does the condition of the blood approach the normal. 4, In a case of formerly marked exophthalmic goitre which clinically appeared to be healed the blood approached the normal, but a slight increase of the large mononucleated leucocytes induced slight toxic influence both in this case and in cases of struma without noticeable thyreoidism. 5, In one case, after resection of the thyreoid gland, a slight improvement in the condition of the blood was observed; in another none except a slight reduction in the number of the large mononucleated leucocytes, but in both cases the time of observation was too short. 6. In the cases given tablets of thyreoid gland an increase in the total number of mononucleated leucocytes and of the polynucleated leucocytes was observed without exception. At first the increase of the large mononucleated leucocytes appears to be relatively greater.

Concerning the Gangrenous Ulcer of the Lower Limbs
 Met with in Natives of East Africa, By Lenz.
 The New Explanation of the Action of Tuberculin,

By ZIELER. 1. Clinical Hypersensitiveness.—Moro, in this the first portion of his paper, considers the relations between the tuberculous reaction and the nervous system. He reports a number of cases of the percutaneous tuberculin reaction that he has observed; he describes five different forms of the reaction. He considers the reaction to be a vasomotor phenomenon produced by a great stimulation of the vasodilator tracts, and classes it as an angeioneurotic inflammation. In tuberculous individuals there is a specific irritability of the nervous system to tuberculin, so to say, a specific nervous allergie.

3. Mueller's Procedure for the Distinction of Acute and Tuberculous Pus by Means of Mila. lons's Reagent. - Hosemann concludes that Mueller's pus test is not applicable in all cases.

5. Certain Forms of Idiocy.-Vogt deals with a study of cases of idiocy and epilepsy due to tuberculous sclerosis.

Carcinoma of the Appendix Vermiformis,

By G. H. Monks. By W. B. Brinsmade. 10. Chyle Cysts of the Mesentery, 11. The Ætiology of Hydronephrosis, By F. E. GARDNER.

Cancer of the Mouth and Tongue.-Warren derives the following conclusions from a review of the literature of this subject: 1. The relation of the lymphatic system to the primary growth is the most important anatomical consideration in operations for cancer of the mouth and tongue. 2. Chronic inflammatory processes of the mucous membrane which do not yield promptly to local treatment, are of importance as predisposing or precancerous conditions and should be treated surgically. 3. Cancer of the mouth and tongue is a local disease limited to the tissues immediately surrounding its point of origin, and to the adjacent lymphatic system. Internal metastases are rare. 4. Microscopical examination of the primary growth is the test of diagnosis. Antisyphilitic treatment should not delay surgical interference. 5. The operative treatment involves (a) preliminary treatment of the oral cavity, (b) protection of the respiratory tract by drugs, by intubation, by pharyngotomy, or by position, (c) removal of diseased tissue and an additional inch of healthy tissue, (d) block dissection of lymphatic tissues of the anterior cervical triangle on one or both sides, (e) as an alternative the block dissection may be made two weeks after the primary operation, (f) the intrabuccal operation should be supplemented by dissection of one or both anterior cervical triangles, (g) the submaxillary route is inadequate for free access to the diseased tissues, (h) the route through the jaw exposes the entire field, but adds to the surgical risk. 6. The ideal operation should contemplate free exposure of the mouth and anterior cervical triangles as a continuous area, with a block dissection of the diseased contents. 7. The mortality varies with the extent of the operation, being between five and thirty-five per cent. Death usually results from shock, sepsis, or bronchopneumonia. 8. In 112 operations for cancer of the mouth and tongue at the Massachusetts General Hospital sixteen patients were free from recurrence more than three years after operation. 9. Of fifty-seven cases of cancer of the tongue

ten patients were cured by operation. 10. Local recurrence of the disease occurred more frequently than recurrence in the lymphatic glands alone. Recurrence more than three years after operation was observed in only one case.

4. Osteoplastic Resection of the Costal Arch. -Wiener observes that every operation of this nature ought to be carefully reported. The operation may be done in two stages under anæsthesia, or in one or two stages under spinal anæsthesia. In the author's case he waited thirty days before doing the secondary operation, and though adhesions had formed they did not complicate the technique. The first step of the operation was done under gas and ether, the second—the resection of the stomach and cesophagus-under spinal anæsthesia. There was very little pain, and the advantage of consciousness is that the patient can be allowed to take a swallow of water after the suturing is completed to see whether there is leakage. The steps of the complete operation are suggested as follows: First operation. Osteoplastic resection of the costal arch through an incision parallel to the free border of the ribs, or through a median and cross incision. Second operation. Resection of stomach and œsophagus and gastrostomy or jejunostomy. Third operation. Œsophagostomy at the root of the neck.

 - mary of Recent Cases of Meningitis Treated by Antimeningococcus Serum, By J. H. M. KNOX, Jr., and F. J. SLADEN.
- Epidemic Cerebrospinal Fever. Royer thinks that an accurate prognosis cannot be given until the patient has been free from symptoms for several months. If a patient is alive and conscious three or four days from the beginning of the attack there is a fair chance of recovery, and if he lives a month the chances are even. The mortality in most epidemics varies from sixty to eighty per cent. The usual methods of treatment are disheartening to doctor, nurse, and relatives. There is no specific medicine for the disease unless Flexner's serum should prove to be such. With morphine the pain may be controlled, delirium lessened, and sleep secured. An ice cap to the head is next in value to morphine. Ice may also be applied to the spine. Early lumbar puncture with removal of nearly all available fluid is sometimes curative. Alcohol and hydrotherapy are sometimes beneficial, especially the warm bath with massage. Strychnine, the bromides, the coal tar preparations, careful feeding, and good nursing are all useful adjuncts in the scheme of treatment.

2. Lumbar Puncture, its Technique and the Value of Cytodiagnosis in Distinguishing Tuberculous Meningitis from the Epidemic Variety.-Burvill-Holmes thinks it strange that this operation is so often omitted when it is so easily performed and is so useful, both from a diagnostic and a therapeutic standpoint. The operation is not free from danger, but accidents have been few. In operating one may use an anæsthetic or not, a single plunge of the needle may be all that is necessary, but everything connected with the operation must be sterile. The patient may sit or lie, as the occasion may seem to indicate, but the fluid will flow more freely if the patient is sitting up. A small trocar and cannula are preferable to a needle in making the puncture. The normal spinal fluid is clear, alkaline, contains a trace of albumin, and has a specific gravity of 1,000 to 1,002; if this is withdrawn epidemic meningitis can be eliminated. In doubtful cases, and those in which the meningococcus and tubercle bacillus cannot be demonstrated, a cytological estimation will be found very advantageous.

5. The Serum Treatment of Epidemic Cerebrospinal Meningitis Based on a Series of Forty Consecutive Cases .- Dunn offers the following conclusions as the result of his studies: 1. The use of the Flexner antiserum is of great value in epidemic cerebrospinal meningitis. Its value is comparable to that of diphtheria antitoxine. 2. The use of the serum will sometimes result in the abortion of the disease, it frequently relieves the symptoms with great rapidity, shortens its course, lessens the liability to sequelæ, and greatly diminishes the mortality rate. 3. The serum should be used as early as possible in all cases even of suspected epidemic meningitis. 4. It should be frequently repeated as long as there are symptoms or any tendency to relapse. 5. Late chronic cases are unfavorable for the use of the serum, but any case in which the diplococci are present has some hope of relief from its use. 6. Some cases are resistant to good effects

from its use.

EDINBURGH MEDICAL JOURNAL.

October, 1908.

I. On Osseous New Growths at the Elbow Following Backward Dislocation of the Radius and Ulna, By DAVID M. GREIG.

The Treatment of Cerebrospinal Meningitis with Flexner's Serum,
 By Claude B. Ker.
 A Theoretical Objection to the Employment of the

Calmette Ophthalmoreaction for Tuberculosis,
By F. Parks Weber.

Osseous Growths at the Elbow Following Backward Dislocation of the Radius and Ulna .-Greig reports three such cases. He cites Jones and Morgan, of Liverpool, who stated that "any muscle may be the subject of bony change, but by far the most commonly affected is the brachialis anticus, followed by the quadriceps and adductor longus." This statement is contradicted by our author, who concludes that such formations have nothing to do with muscle, though they may be in anatomical proximity, and therefore, when reabsorbed, the muscles are left unaltered in their natural usefulness. Dr. Greig then remarks that in a recent simple dislocation at the elbow, or at any other joint, the parts have not lost their natural resiliency, muscles are still overstretchable, so the as to allow the displacement and replacement

of the bones with a minimum tearing of the soft parts. If such dislocation is reduced at once, it is most unlikely that anything unexpected will result, as the bruised tissues soon return to their normal condition. Should, however, undue violence be exerted in the production of the dislocation or in the replacing of the bones; or should the soft tissues have lost their resiliency either by infiltration with inflammatory products or from too prolonged stretching in abnormal positions, then such injury is inflicted as would be likely to produce a tearing from their attachments of those muscles on which the greatest strain is thrown during the accident or the subsequent manipulations. If the tearing is sufficiently severe to raise the periosteum, then will occur the escape from the Haversian canals or from the periosteum of the elements which are necessary for the production of callus. Such bruising takes place in proportion to the force producing the injury or employed afterwards, and varies with age and the stiffness of the muscles. In some cases it has been recorded that new bone thus formed about an injured joint actually contained a blood cyst-surely incontrovertible evidence that the new bone is formed, not by blood clot, but in blood clot by bone forming elements entering into the effusion produced at the time of injury; that is to say, at the time of the accident or during reduction. Herein lies a simple and satisfactory explanation of this fortunately rare occurrence. About the elbow it is most common in connection with the tearing of the attachment of the brachialis anticus to the ulna, but there is no reason why similar osteophytic growths should not occur about the attachment of other The circumstances which lead to the muscles. formation of new bone in these cases are not very dissimilar from the formation which takes place in inflammatory conditions raising the periosteum, or in the stripping of the periosteum by subperiosteal hæmorrhage in infantile scurvy.

Proceedings of Societies.

SIXTH INTERNATIONAL CONGRESS ON TUBER-CULOSIS.

Held in Washington, D. C., September 28, 22, and 30, and October 1, 2, and 3, 1408. (Continued from page 960.)

Fibrotuberculoma of the Pleura.—Dr. EDWARD RIST, of Paris, reported the case of a tumor which took the place of an atrophied lung, which weighed ten pounds, and which was attached to the thoracic wall by a pedicle. Sections made from the growth showed it to be a fibrotuberculoma.

The Chemistry of the Tubercle Bacillus.—Dr. VICTOR C. VAUGHAN, of Ann Arbor, Mich., said that after freeing tubercle bacilli, which were grown in large quantities, from fats, waxes, and other substances soluble in alcohol and ether, the organisms were split by an alcoholic solution of an alkali into a poisonous portion and a nonpoisonous portion. The poisonous portion killed animals within a few months, when given in doses of from seventy-five to one hundred milligrammes. The nonpoisonous por-

tion "sensitized" animals to the tubercle bacillus, but was without poisonous action. That portion of the split bacillus was being used in the treatment of tuberculosis in man; but it was too early to state whether it was better than the old tuberculin or not.

On the Action of Soaps upon the Vitality and Immunizing Property of Bacillus Tuberculosis. -Dr. Hideo Noguchi, of New York, said that it had been demonstrated by previous experiments that oleate soaps, when combined with the blood serum, possessed some of the distinctive properties of complements, and that they exhibited bactericidal activity in a high degree. The action of such soaps was tested upon the Bacillus tuberculosis. In the first place, oleate soaps possessed the power, when emploved in appropriate concentrations, of modifying otherwise virulent tubercle bacilli, so that when subsequently inoculated into guinea pigs, they either failed to cause the lesions of tuberculosis or the lesions were much less in degree than they were in the control animals. When death occurred from tuberculosis in the animals inoculated with the bacilli, it occurred invariably much later than in the control animals. Second, a guinea pig that failed to have tuberculosis, when inoculated with the bacilli treated with oleate, showed a definite degree of immunity to vigorous and otherwise virulent cultures of the bacillus. Such resistant guinea pigs either had no lesions after the inoculation of large quantities of the virulent cultures, or they showed lesions of a much milder degree and of slower evolution than the lesions developed in the control animals. Third. oleate soaps possessed distinct bactericidal properties for the bacillus. The addition of the soaps to an otherwise favorable culture medium prevented the growth of the bacillus even when the quantity was small. Solutions of the soaps, brought into contact with the emulsified bacilli, diminished the ability of the bacilli to grow in cultures and to cause active infections in animals. Solutions of soaps, less in amount than were required to inhibit the growth completely, reduced the number of developing bacilli. There was a relation between the bactericidal property of the soaps and the immunity produced in guinea pigs by the inoculation of the soap treated cultures. The bactericidal effect of the oleate soaps was far greater than that of their component acids and bases, and could not be reproduced by the separate chemical constituents of the soaps. The bacilli isolated from cold blooded animals were more resistant to the bactericidal effects of the soaps than those isolated from warm blooded animals. Fourth, it had been established by Conradi that substances resulting from the autolysis of organs might be actively bactericidal. Bartel had shown that the products of the autolysis of lymph nodes were injurious to the bacillus, and that such products reduced the virulence of the bacilli. The precise constituent of the autolyzed organs upon which the bactericidal action depended was not known, but there was reason to believe that it belonged to the lipoids. The experiments forming the basis of the paper read made it probable that the soaps formed during that process might be one of the important factors, if not the chief factor, in the phenomenon of the destruction of the bacilli and in the reduction of their viru-

The Part of Enzymes in Tuberculous Lesions. -Dr. Eugene L. Opie, of New York, said that he had studied the enzymes of tuberculous lesions produced by inoculating animals in the pleural cavities with tubercle bacilli. The enzyme peculiar to the polymorphonuclear leucocytes was present a short time after the inoculation, but it diminished in activity quickly. A second enzyme which digested proteid in a weak acid solution was present in great abundance until caseation occurred, when it disappeared. The serum of the exudate which accumulated in the chest lost the power possessed by the serum of the blood to inhibit this and similar enzymes. The enzyme which acted in an acid medium was probably present in the epithelioid cells of the tubercle, and was similar to that of the large uninuclear cells of an inflammatory exudate, which the epithelioid cells resembled. Autolysis caused by the enzymes not held in check might explain the occurrence of caseation in poorly vascularized tissues containing the products of the tubercle bacillus.

Humoral Properties of Tuberculous Exudates; Prognostic and Therapeutic Value.—Dr. PAUL COURMONT, of Lyons, said that a large quantity of a tuberculous exudate was a good prognostic sign. But a quantity as much as one tenth of the bodily weight of the animal was often followed by disastrous results. In cases in which smaller quantities were followed by bad clinical results it indicated that absorption might predispose the individual to infection later. The serum in a pleuritic exudate was distinctly bactericidal. The exudate agglutinated the tubercle bacillus, and the greater the agglutinating power the better the prognosis. The author maintained that the exudate was excreted by the endothelial cells and that it was not a transudate. In estimating the bactericidal properties of the serum of a pleuritic exudate it was difficult to establish a reasonable basis for comparison.

Report on Serological Studies in Tuberculosis. -Dr. H. von Schroetter, of Vienna, reported for Dr. K. REITTER and Dr. E. STOERK upon their serological studies, which were intended to extend the methods at the disposal of the clinician for the early diagnosis of tuberculosis. It had been demonstrated that the serum of tuberculous patients, especially in the early stages of the disease, contained substances of a colloidal nature which were precipitated by the adition of double the amount of 0.5 per cent. car-bolized sodium chloride solution. The addition of an ethereal extract of tubercle bacilli of a strength of one half gramme of tubercle bacilli to two hundred cubic centimetres of carbolized salt solution rendered the precipitating reaction positive in even a higher percentage of cases. In the diagnostic application of this reaction certain diseases, probably accompanied by lipæmia, must be excluded, such as tumors in retrogressive metamorphosis, diabetes, and occasionally infections of a nontuberculous char-

The Tinctorial Characters of the Tubercle Bacillus.—Professor Teissier, of Paris, described the morphological and tinctorial characters of tubercle bacilli grown in glycerin. He described the granules that were produced in the organisms in from three to four weeks. He said that he could produce changes in the tubercle bacilli by chemical

methods which were similar to those produced in the homogeneous culture by the action of glycerin and glycogen.

Dr. PAUL COURMONT said that homogeneous cul-

tures grew well in a glycogen solution.

The Rôle of the Fatty Acids of the Bacillus Tuberculosis .- Dr. CAMUS and Dr. PANNIEJ said that they had performed experiments to determine the effect of the free fatty acids which were thought to account for the acid fast properties of the Bacillus tuberculosis. They found that they were able to color free fatty acids by the same tinctorial methods that were used for the staining of the tubercle bacillus. They also found that after the tubercle bacillus had been deprived of its fatty acid it had lost its acid fast properties. They further found that when free fatty acids were injected into animals they produced follicular lesions, caseous lesions, and other changes similar to the changes in structure produced by the tubercle bacillus. Injection of the free fatty acids seemed to produce a local supersensitiveness.

Some Considerations Concerning the Lesions of Tuberculosis.—Dr. WILLIAM T. COUNCILMAN, of Boston, said that the tuberculous lesion was modified by the variety of tubercle bacillus that produced it, by the number of tubercle bacilli producing the disturbance, by the susceptibility of the animal, by the route of the infection, by the age of the animal, and by the presence or absence of a mixed infection. A tuberculous lesion was subject to all the degenerations seen in the acute infections. He believed that the epithelioid cells were derived from

the endothelium lining the bloodvessels.

Dr. A. S. WARTHIN, of Ann Arbor, Mich., said that he could not agree with Dr. Councilman that the epithelioid cells were derived from the endothelium of the bloodvessels. He referred to the epithelioid elements found in the placenta, which, he said, were certainly not derived from the endothelium

Anatomical Characteristics of Tuberculous Infections and their Relation to Tuberculin Reactions .- Dr. S. Arloing, of Lyons, said that the lesions that accompanied tuberculous infection did not always represent tubercles visible to the naked On account of the lower virulence of certain tubercle bacilli the lesions were sometimes so slight that they were visible only on histological section. On the other hand, the diminution in the virulence of an organism might bring about a certain modification of the lesions, which in turn would bring about profound changes in the reaction of the body. Again, there were some instances in which the bacilli spread in the body of the animal and exhausted themselves without leaving trace of their passage. In such a case the infection showed itself by the presence of the bacilli in the tissues only, or by the experimental methods of diagnosis, such as the tuberculin reaction and the serum agglutination test. Whatever the character of the tuberculous infection, the patient would at some time react positively to these experimental tests. Hence these tests revealed the existence of bacillary infection rather than the presence of appreciable tuberculous lesions. On this account the disagreement between the experimental diagnosis and the post mortem microscopical diagnosis might be expected, but it was more apparent than real. The number of these discrepancies would be diminished by seeking the histological changes and the bacilli at autopsy. In the absence of both histological changes and of bacilli a positive tuberculin reaction should be regarded as proof that a latent infection was either extending in the body or was in the process of recovery. During life the information conveyed by a positive reaction to tuberculin would usually be found to be accurate. The methods of diagnosis and prognosis must be perfected in order to foretell as accurately as possible the future of a tuberculous infection.

An Anatomical and Pathological Study of the Nonfollicular Lesions of Tuberculosis. — Dr. Léon Bernhard, of Paris, said that it was customary to consider as tuberculous lesions only the tubercle with its various forms of structure and of evolution. Around the tubercles, however, there were alterations which were usually said to be inflammatory in character, and at a distance from the tubercles other inflammatory foci might be found. These changes were set up by the tubercle bacillus just as much as the tubercle was produced by that organism. The reactions in the various tissues which were produced by the tubercle bacillus, as well as by other pathogenic organisms, were congestions, infiltration of the connective tissues with a lymphocytic exudate, sclerosis, fibrinous exudate, and simple hyperplasia of the lymph nodes. In the parenchymatous cells of the body all varieties of degeneration were found, as well as hyperplasias and neoplastic formations. These lesions were called by the writer the "follicular lesions" produced by the bacillus. On the other hand, he described a number of nonfollicular lesions due to the Bacillus tuberculosis. He used the term "nonfollicular" because it did not indicate anything about the pathogenesis of the lesions. The term "toxinic" bad term, as it implied an interpretation of the pathogenesis of the lesions, and the term "inflammatory" was bad because it implied that the follicular lesions were not inflammatory. On account of the characters of these lesions, which they possessed in common with other lesions of a similar nature, they were at first thought to be due to the secondary infections, and not to the tuberculous infection. Other observers thought that they were due to the action of the diffusible poisons of the tubercle bacillus. The author maintained that the results of several series of experiments had demonstrated that the diffusible poisons of tuberculosis were unable to produce lesions similar to those known as the nonfollicular lesions. On the other hand, the Bacillus tuberculosis itself was able to produce all of the tissue changes described under the term nonfollicular. The reason why the Bacillus tuberculosis sometimes produced follicular lesions and sometimes nonfollicular lesions was not dependent upon the virulence of the organisms, but rather upon the number of organisms operating upon the tissues which showed the changes, and upon the intensity of the toxic action. He maintained that there was no essential difference between the follicular lesions and the nonfollicular lesions; they were different reactional aspects dependent upon unequal toxic action.

The Frequency of Healed Tuberculosis of the Mesenteric Glands, with Particular Reference to the Relationship between Hyaline Deposits in these Glands and the Healing of Tuberculous Lesions.—Dr. A. S. Warthin, of Ann Arbor, Mich., said that the mesenteric and the retroperi-toneal lymph nodes contained hyaline deposits or hyaline changes in almost every case that came to the autopsy table. The hyaline substance varied in size from that of a red blood corpuscle to that of larger and smaller macroscopic islands. hyaline masses were looked upon by the writer as old healed infectious lesions, probably tuberculous, in the majority if not in all of the cases. He believed that the intestinal route of infection was thus shown to be just as important as the pulmonary route in the development of tuberculosis. In only a few cases could tubercle bacilli be demonstrated in the lymph nodes.

Dr. W. H. Welch, of Baltimore, said that this announcement of Dr. Warthin's was startling. He was not absolutely convinced that the statement was true, but he would investigate the question. If the statement was found to be true, it indicated that the intestinal route was the predominant one in infection with tuberculosis. He inquired whether any

areas of calcification had been found,

Dr. Warthin said that calcification was frequently associated with these hyaline lesions. He thought that the hyaline patches might be due to

healed typhoid lesions.

Dr. WILLIAM T. COUNCILMAN, of Boston, said that tuberculosis could undoubtedly lead to hyaline degeneration, but that hyaline degeneration could also occur as the result of lesions set up by a large number of other infective agents.

Dr. Francis Harbitz, of Christiania, agreed in the main with the statement of Dr. Warthin.

Dr. Warthin said that other infective agents

might produce the same hyaline changes.

Analysis of 1,000 Consecutive Autopsies in Montreal with Reference to the Incidence of Tuberculosis in the Different Organs.—Dr. J. George Adami and Dr. John McCrae, of Montreal, said that in the last 1,000 autopsies held in the Montreal General Hospital there were evidences of past or present tuberculosis in 417, or 41.7 per cent. One hundred and fifty-one cases showed healed lesions; ninety-three cases showed latent lesions; twenty-two cases showed slight active lesions; twenty-three cases showed generalized lesions; eighty-five cases showed pulmonary lesions; twelve cases showed bone lesions; and ten cases showed genitourinary lesions.

(To be continued.)

Wetters to the Editors.

ANCIENT GREEK MEDICINE

126 EAST THIRTY-FOURTH STREET,

To the Editor:

Kindly permit me some remarks on the article, thus entitled, by Dr. Charles W. Super, of Athens, Ohio, published in your issue to-day. It appears to me that the learned author did not do full justice to the Greek physicians of antiquity.

The first Greek physicians were priests of Asclepios (the Romans called him Æsculapius), the Greek god of the art of healing, and they called

Greek god of the art of healing, and they called themselves Asclepiades. Medical knowledge was transmitted from father to son in the Asclepian families, and the pupil had to take an oath not to reveal the secrets entrusted to or inherited by him. Hippocrates, who lived in the fifth and fourth centuries B. C., the son of an Asclepian priest, was the first who placed medicine on a scientific basis, who made medicine a science. He is the greatest

and the model physician of all times.

The Greek physicians during and after the time of Hippocrates continued to call themselves Asclepiades, descendants of the god Asclepios They congregated in the temples of Asclepios; their practice, however, was no longer merely temple medicine mixed up with the mystic, but it was based upon facts derived from observation at the bedside. The Greeks were accurate observers, and they endeavored to explain physiological and pathological processes of the human system. Here we encounter the first distinction in medicine between science and faith, mentioned by Dr. Super in quoting the words of Socrates, the contemporary of Hippocrates. These same words of Socrates, applied to metaphysics by Kant, have played an important rôle in theology. In this connection it may be mentioned that the designation "Christian Science," adopted by a new school of the art of healing, is self contradictory, since the adherents of this school exclude everything that is scientific and confine themselves to matters of faith.

It was principally the observation at the bedside which the Greeks developed to such a high state of exactness that we, even at this time, are obliged to look up to it as an example that we should emulate in our work. No change in the condition of the patient remained unobserved, and the different symptoms of the different diseases were so well described that later observers, even those of our times, had, and have, hardly anything to add. Medicine of the ancients, before the Alexandrian era, was confined to the study of the symptoms; pathological

anatomy did not exist.

Admirable were the accomplishments of surgery when we consider that the ancients had no exact knowledge of the anatomical construction of the human body, and that, possessing only rather primitive surgical instruments, they undertook great operations, such as trephining, amputations, resections. The ancient Greeks were well advanced even in the treatment of diseases of the eye, as operations for cataract were undertaken by them.

After the conquests of Alexander the Great, culture and learning gravitated toward the Orient, and Alexandria became the principal centre of classical education and knowledge. This period of Greek history is called the Alexandrian, and it began in 323 B. C., attaining its highest glory in 30 B. C., when it came under the control of Rome.

As Dr. Super states, it was first in Alexandria where physicians were permitted to enlarge their knowledge by means of dissection of human ca-

davers.

From Alexandria, Greek medicine took its way to Rome. Physicians of the Orient, who since the second century B. C. immigrated into the capital of the new empire, excited the admiration of the Romans, demonstrating to them what physicians who merit this name were able to accomplish.

Medicine, so far as it originated in Italy, was restricted to the knowledge of domestic remedies and to minor surgery, and it soon gave way to Greek medicine, the superiority of which speedily influenced the physicians of Rome to become the pupils of Greek physicians and to adopt their teachings.

The Romans had not looked upon medicine as a noble art or vocation, it being frequently practised by slaves; and this is why the Romans did not contribute to enrich it. Medical science, even in Rome, remained in the hands of the Greeks; all the valuable works were written by Greeks and in the Greek language. Galenos, the greatest theorist of antiquity; Dioscorides, the pharmacologist; Soranos, the gynæcologist, all were Greeks. The Latin language can pride itself on only one medical book of significance, and this was written, not by a physician, but a layman, the highly cultivated A. Cornelius Celsus.

In old Hellas, the physician, "iatros" (that is, the one that heals), was highly respected, although at times, as has been the custom ever since, he was blamed and derided. When the Asclepiades spread all over Greece, it was no longer sufficient, as it had been previous to Hippocrates, to transmit the knowledge of medicine merely from father to son; Asclepian schools were founded, and students of these schools were admitted into the profession after having finished their medical school education and after having taken the Hippocratic oath. There were physicians firmly established who visited their patients or received them in their homes; there were also wandering physicians who traveled from town to town in order to practise their profession. Patients not confined to bed were treated. not only in the house of the physician, but also in the iatreion (medical workshop), a large building, generally situated on the main street, with free access of sunlight. Such buildings were given to municipal physicians even as late as the time of The nosocomoi (nurses, nosos, disease, comeo, I take care of) were slaves. Patients able to pay could remain in the iatreia until their final recovery.

The remuneration of physicians originally consisted in presents, but at the time of Hippocrates payment in money was already customary. Physicians received also public praise, the "crown of honor," the freedom of the city, the privilege of eating at the king's table. Physicians employed by the state received a yearly salary, as high as \$2,000 in some instances. Rich people would pay enormous sums for a successful treatment, and a case is recorded in which \$200,000 was paid. The state furnished the means for elaborate iatreia, with a rich equipment, and levied a special tax for the physician of the state; it was sometimes the case in rich cities that the citizens were exempt from all

taxes except for physicians.

A. Rose.

Book Rotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Anatomy, Descriptive and Surgical. By Henry Gray, F. R. S., Fellow of the Royal College of Surgeons; Lecturer on Anatomy at St. George's Hospital Medical School, London. Seventeenth Edition, Thoroughly Revised and Reedited, with Additions, by John Chalmers Da Costa, M. D., Professor of the Principles of Surgery and of Clinical Surgery in the Jefferson Medical College, Philadelphia, and Edward Anthony Spitzka, M. D., Professor of General Anatomy in the Jefferson Medical College, Philadelphia. Illustrated with 1,149 Engravings. Philadelphia and New York: Lea & Febiger, 1908. Pp. xxvi-33 to 1,614.

This edition of the late Mr. Gray's work, which has been a favorite with the profession for half a century, is enriched by a thoroughly revised section on the nervous system, by Dr. Edward A. Spitzka, who has done the work exceedingly well. It is also enriched by many added illustrations, especially a number of beautiful cuts from Spalteholz. The nomenclature of the German Anatomical Society is given in conjunction with the old terms, but with a number of deviations, and there are numerous errors in the spelling of anatomical names. These will doubtless be corrected in subsequent printings.

An Alabama Student and Other Biographical Essays. By WILLIAM OSLER, M. D., F. R. S., Regius Professor of Medicine, Oxford; Honorary Professor of Medicine, Johns Hopkins University, Baltimore. New York: Oxford University Press, American Branch; London: Henry Frowde, 1908. Pp. 334.

These collected addresses of Dr. Osler's are above all criticism; they are simply fascinating. In all of them the substratum is biographical, and it is in biography that the author is at his best. The "Alabama student" was Dr. John Y. Bassett, of Huntsville, and the other men around whose lives Dr. Osler weaves his charming essays were Thomas Dover. John Keats, Oliver Wendell Holmes, John Locke, Elisha Bartlett, William Beaumont, Pierre C. A. Louis, William Pepper, Alfred Stillé. Sir Thomas Browne, Hieronymus Fracastorius, and William Harvey. No physician can read the book without a profound realization of the elevating influence of the great men of the profession.

The Air and Ventilation of Subways. By George A. Soper, Ph. D., Member of the American Society of Engineers, etc. First Edition, First Thousand. New York: John Wiley & Sons; London: Chapman & Hall, Limited, 1908. Pp. ix-244.

This volume is the result of studies for two years and a half for the Board of Rapid Transit Railroad Commissioners for the city of New York and the Interborough Rapid Transit Company, the lessees of the subway. Its object is to make available the account of the essential features of the investigation and thus be of service to many who are not trained in sanitary science, but who are interested in knowing the composition of good and bad air and the way in which it should be treated in subways and other inclosed spaces. Much valuable information on the composition of air in cities, apart from subways, is also supplied, and many formulæ and tables

which make the book rather too technical for the average reader. Many diagrams also illustrate the different phases of the subject. The book will be a useful one for reference purposes.

The Physician's Visiting List (Lindsay & Blakiston's) for 1909. Fifty-eighth Year of its Publication. The Dose Table herein has been Revised in Accordance with the New U. S. Pharmacopæia (1905). Philadelphia: P. Blakiston's Son & Co., 1908. (Price, \$1.)

Blakiston's Physician's Visiting List appears for the fifty-eighth time, for the year 1909, and is made up for twenty-five, fifty, seventy-five, and one hundred patients seen daily. Besides this daily visiting list and memoranda, we find the usual practical addenda, such as a table for calculating the time of parturition, the immediate treatment of poisoning, and a dose table in the English and the metric systems, etc.

On Means for the Prolongation of Life. Third and Enlarged Edition of a Lecture Delivered before the Royal College of Physicians on December 3, 1903. By Sir HERMANN WEBER, M. D., F. R. C. P., Consulting Physician to the German Hospital, etc. London: John Bale, Sons, & Danielsson, Ltd., 1908. Pp. viii-214. (Price, 4s, 6d.)

Sir Hermann Weber's original lecture has of course been very much amplified in the form in which it now appears. There is nothing strikingly original in the book, but it presents us with a well arranged collection of wise precepts for the preservation of health.

Atlas der Syphilis und der venerischen Krankheiten mit einem Grundriss der Pathologie und Therapie derselben von Hofrat Professor Dr. Franz Mracek in Wien. Zweite vermehrte und verbesserte Auflage. Mit 81 farbigen Tafeln nach Original-Aquarellen von Maler 'A. Schmittson und 26 schwarzen Abbildungen. München: J. F. Lehmann, 1908. Pp. xii-218.

This atlas was reviewed by us at the time of the appearance of the first edition in 1897. Since then its distinguished author has died. The present edition has been prepared, from material left by the author, by K. H. Schirmer, who was associated with him. Many attempts have been made to represent cutaneous lesions in color. Most of them have been more or less failures. In the one before us the colors are not true to life. They are too lurid. Thus, plate No. 17, of a generalized papular syphilide, might well serve for one of a drug eruption. Plate No. 23, perhaps on account of its number, is peculiarly unlucky, as some of the lesions have escaped color almost entirely. It is well that plate No. 28 is labeled "Pustular Syphilide," as otherwise it would be unrecognizable, and it is scarcely so as it is. No. 37 presents a picture never seen on land or sea. It is so hairy that it might be that of an ape. pictures of the lesions of the female genitals should be used by the Society of Sanitary and Moral Prophylaxis, a society that is doing good work in spite of its peculiar title. They are so frightful that they should act as deterrents. The pictures of the initial lesion and of mucous patches are good, and the black and white illustrations are the best of all. Indeed, the chief value of the atlas is that it is rich in pictures, its one hundred and seven illustrations giving many phases of this protean disease, syphilis.

The second part of the book, two hundred and three pages, is devoted to a treatise on syphilis and

venereal diseases. The text is good, though not exhaustive. Not only are the skin lesions of syphilis described, but also the effects of the contagion on the internal organs, joints, eyes, ears, and nervous system. The Spirochæta pallida is accepted as the probable cause of the disease, and inunctions are commended as the best means for combating it, all things considered.

Diseases of the Spinal Cord. By R. T. WILLIAMSON, M. D. (Lond.), F. R. C. P., Assistant Physician, Royal Infirmary, and Lecturer in Medicine, Victoria University, Manchester. With One Hundred and Eighty-three Illustrations and Seven Plates. London: Henry Frowde and Hodder & Stoughton; New York: Oxford University Proceedings of the Pro sity Press, American Branch, 1908. Pp. xi-432.

This volume represents, the author tells us, his lectures and studies as presented to his students in Manchester during the past fifteen years. They have been carefully revised and edited, and make a very commendable addition to the textbook literature of diseases of the spinal cord. It is more than the conventional textbook, however, and is therefore to be recommended, not only to junior students, but to practitioners and even to professed specialists. To the latter the book will appeal by reason of its scholarly character and the author's unusually skilful mode of presentation.

The general arrangement is largely conventional and anatomical. The opening sections deal with structure, pathological history, and functions. Then follows a full discussion of the symptoms of spinal disease, which is brought well up to date. Methods of examination by electricity, x rays, and spinal puncture are then discussed. Chapter VI deals with the diagnosis and localization of diseases of the cord. Then follow the descriptions of different disease processes. The author arbitrarily divides these into four groups-those with symptoms of

transverse lesion, those with symptoms of atrophic

paralysis, those with spastic paresis, and those with

ataxia-a clinical grouping which, while pedagogically simple, is too much so for the best purposes.

The diseases of the spinal meninges fall outside of the general scheme, as do also the traumatic affections of the cord and the clinical and pathological features of spinal syphilis. From the standpoint of bookmaking the work is specially commendable. Taken all in all, it is a very creditable performance. cert inly one of the best of its kind in English.

Transactions of the American Padiatric Society. Nineteenth Session, Held at the Arlington Hotel, Washington, D. C., May 7, 8, and 9, 1907. Edited by LINNAUS EDFORD LA FETRA, M. D. Volume xix. New York: E. B. Treat & Co., 1908. Pp. 220.

This volume follows in the general make up its predecessors. It contains the usual society notes and the minutes of the nineteenth annual meeting, together with the papers and addresses presented to the society. Among the contributors we find B. K. Rachford, Henry L. K. Shaw, Leon K. Baldauf, Thomas M. Rotch, Ariel W. George, John Howland, Charles H. Dunn, Thomas S. Southworth, Charles G. Kerley, Maynard Ladd, R. G. Freeman, F. Forchheimer, J. P. Crozer Griffith, Frank S. Churchill, S. S. Adams, J. L. Morse, F. Huber, W. P. Northrup, C. G. Jennings, H. M. Rich, C. F. Martin, J. A. C. Tull, J. H. M. Knox, G. N. Acker, and John Ruhräh.

New Remedies.

Sulfoid is the trade name of a colloidal sulphur for which a German patent has been issued. It is a grayish white powder, which dissolves to form a milky white solution, which, seen through transmitted light, is iridescent blue. The solutions should be freshly prepared, as they deposit sulphur on Sulfoid is insoluble in alcohol, etheralcohol, acetone, and concentrated solution of sodium chloride, but soluble in physiological salt solution. It contains about 80 per cent. of sulphur and 20 per cent. of albumin. With fats, lanolin, petrolatum, wax, and soap it mixes readily to form ointments and soaps, which exhibit the sulphur in an extraordinarily fine state of suspension.

Sullacetin is a potassium-sodium compound of pyrocatechinmonoacetic acid and guaiacolsulphonic acid, which forms a white, odorless, slightly bitter salt. It is used in tuberculosis, being administered in powder or tablet form in 71/2 grain doses.

Suprarenine (synthetic) is made by condensing catechol, with chloracetic acid to form chloroacetylcatechol, which is then treated with methylamine. and the resulting methylaminoacetylcatechol is reduced to dihydroxyphenylmethylaminomethylcarbinol, or synthetical suprarenine, which, in the form of the hydrochloride, is said to be indistinguishable in physiological action from the natural alkaloid of the suprarenal gland.

Thyreotheobromine Pills, used in the treatment of obesity, contain in each dose thyreoid gland substance 3/4 grain, and theobromine sodium salicylate, in combination with quinine and podophyllin.

Tuberculin Ointment is composed of equal parts of tuberculin-old and anhydrous wool fat, the tuberculin being incorporated with the wool fat, heated to 68° to 154° F. Kept on ice the ointment will retain its activity for months. It is used to determine the existence of tuberculosis by inunction, 10 drachms being sufficient for 100 test applications.

Tuberculin Suppositories.—A new method of administering tuberculin is described by A. Lissauer in the Deutsche medizinische Wochenschrift. No. 33, 1907. The tuberculin is given by the rectum by the aid of hollow suppositories, in which the drug is placed, either alone or mixed with petrolatum, olive oil, or a 5 per cent. carbolic acid solution. The top is sealed either by heating or by painting over with a mixture of 3 parts beef tallow and I part lard.

Velledol is the name of one of the new mistletoe derivatives which have recently been introduced into medicine. It is said to be the active principle of viscum album, and is given internally by the mouth in doses of 0.5 gramme, and hypodermically in doses of 0.5 gramme, and hypodermically in doses of 0.001 gramme, several times a day. It is said to be useful in relieving menstrual disorders and in checking post partum hæmorrhages.

Zinc Boropicrate (Chrysl).—Picric acid, 349; boric acid, 62; water, about 400; are heated together, and zinc oxide, 82, is added to the solution. The resulting yellow powder is introduced as a sedative or drying agent for use in the treatment of skin affections and for ophthalmic application.

Official Melus.

THE RED CROSS IN THE ANTITUBERCULOSIS WAR.

A Plea for Centributions through a Christmas Stamp.

By S. Adolphus Knopf, M. D., New York,

Professer of Phthisiotherapy at the New York Postgraduate Medical School and Hospital; Associate Director of the Chine iss Fullmonary Diseases of the Health Department; Attending Physician to the Riverside Sanatorium for Consumptives of the City of New York, etc.

To give to the medical profession and through it to the public at large an idea of what is being done in Germany by the Red Cross Society in the combat of tuberculosis, what is being done and what also might be done in this country by the same organization, and to arouse, if

possible, a greater enthusiasm and support on the part of the laity as well as the medical profession, I will give in what follows the substance of two recent addresses on the subject. One I delivered in Brooklyn on October 27th, at the Ridge Club, before the New Utrecht Red Cross; the other, on October 28th, at the home of the Honorable George B. McClellan, mayor of New York, before the New York County Subdivision of the American National Red Cross. The suggestions offered received the cordial approval and hearty support of both audiences.

One of the most interesting contributions which were presented at the International Congress on Tuberculosis in Washington, which has just come to a close, was a book of nearly 250 pages, prepared by B. von dem Knesebeck, the president, and Professor Pannwitz, the secretary of the German Red Cross Society. The work was entitled Das Deutsche Rothe Kreuz und die Tuberkulose Bekümpfung (The German Red Cross and the Fight against Tuberculosis). In this interesting volume there are enumerated, illustrated, and described:

1. Sanatoria established and conducted by the German Red Cross Society, of which the most important ones are the one at Grabowsee, the sanatorium for women called *Vogelsang*, near Magdeburg, and the *Sophie Sanatorium*, near Berka, on the Ulm, in Saxony-Weimar.

2. So called research stations and societies for the purpose of coming to the assistance of such families as are deprived of their bread winners because of the latter's sojourn in a sanatorium. They are the Association against Tuberculosis of the Patriotic Women of Charlottenburg, and the Association against Tuberculosis of the German Sisters of Charity.

3. Homes for tuberculous convalescents—adults and children—at Berlin and Frankfort on the Main.

4. Sanatoria for tuberculous children—the Vicitoria Luise Kinder Heilstätte at Hohenlychen, and the Cecilienheim at the same place.

5. The agricultural colony for the tuberculous, known as the Königin Louise Andenken.

6. The vacation colonies, also located at Hohen-

lychen.
7. A school for training nurses for the tuber-

culous.

8. The seaside home at Swinemunde for the tuberculous wives and children of noncommissioned

officers of the German army.

9. Gardens or horticultural colonies for tuberculous workers.

10. The bureau which has for its purpose to procure work for the patients leaving the sanatorium,

All these institutions, societies, and bureaus are a part of the work which the Red Cross of Germany is doing. The Woman's Branch alone of the Red Cross has 400,000 members, its funds and the value of its property amount to over \$5,000,000, so you can perceive the importance of the work the Red Cross can do in Germany in time of peace as well as in time of war.

If I am right, the Red Cross was founded at Geneva in the year 1863. It owes its origin to the feeling of sympathy awakened throughout Europe by the sufferings occasioned by the Crimean war. The object of the Red Cross Society is in the main to mitigate the evils inseparable from war. All the civilized nations of the world have branches of this truly international association.

Ever since its establishment, forty-five years ago, this unique and humane society has done glorious work in all the wars which civilized nations have chosen to wage. With the advance of higher humanitarian conceptions and thanks to the enthusiastic labors of high minded men and women in all countries, wars are becoming less frequent. But we have not yet advanced far enough to say with certainty there shall be no more war; and to lessen the horrors of the battle field when war does come, the Red Cross societies all over the world continue their existence and hold themselves in readiness.

Some of them—as, for example, the before mentioned German Red Cross Society, and, of late, some branches in our own country—have in the meantime directed their energies toward an enemy far more terrible, far more murderous, far more costly than the mightiest army of the mightiest

nation. If I say far more murderous I say so advisedly, for can you conceive of an enemy which would slay every year, and year after year, more than 100,000 inhabitants in the United States alone? Yet this enemy has existed within our midst for years, exists and will continue to exist unless we begin to fight him more vigorously than we have done heretofore.

That great, immortal poet and physician, Oliver Wendell Holmes, has called this enemy "the great white plague," but it is also known to us all by that significant word consumption. This latter word has two meanings. The disease bearing this name consumes not only the vital forces of man and leads him to an early grave, but it also, in most instances, consumes the material prosperities of the individuals

of families afflicted.

Professor Victor C. Vaughan, of Ann Arbor, a careful observer, told us at the recent Tuberculosis Congress at Washington that from 200,000 to 250,000 citizens of this country die annually of tuberculosis. Taking now only the lower estimate, we must in our calculation admit that two thirds to three fourths of these, our fellow countrymen, die between the ages of eighteen and forty-five, that is to say, at the time of life when the earning capacity is greatest. When we now, with Darlington, esti-mate the value of a single individual during the prime of his life to be only \$1,500, and taking again the lower estimate of two thirds, and not the higher estimate of three fourths, the economic loss which accrues to the United States through this single disease is no less than \$150,000,000 annually. Add to this the anguish and sorrow, the tears of mothers, orphans, and widows, and then you will agree with me when I say that tuberculosis is the most murderous, most costly affliction of all the enemies of the human race.

Another interesting and more startling calculation of the cost of tuberculosis in the United States and its reduction was presented at the International Congress on Tuberculosis in Washington by Professor Irving Fisher. He estimated the death rate from tuberculosis in all its forms in the United States at 164 per 100,000 of population, and the number of deaths in 1906 as 138,000, and he summarized as follows: "At this rate, of those now living in the United States 5,000,000 people will die of tuber-The average age at death for males is 37.6 years; for females 33.4 years. The expectation of life lost (though estimated on a specially high mortality rate) is at least twenty-four years, of which at least seventeen fall in the working period. The average period of disability preceding death from tuberculosis exceeds three years, of which the latter half is a period of total disability."

The money cost of tuberculosis, including capitalized earning power lost by death, exceeds \$8,000 each death. The total cost in the United States exceeds \$1,100,000,000 each year. Of this cost about two fifths, or over \$4,40,000,000, falls on others than the consumptive. An effort to reduce the mortality by one fourth would be worth, if necessary, an investment of \$5,500,000,000.

Yet the experience of the past twenty-five years has demonstrated the feasibility of the successful

combat of this enemy. Thanks to the epoch making discovery of the great German scientist, Robert Koch, we know the very nature of the disease, its microbic origin, and the means of preventing its spread. Thanks to the labors of such men as Brehmer and Dettweiler in Germany, and Trudeau and Biggs in the United States, we have learned how to treat and control, or, in other words, successfully fight this enemy. By education and sanitary control we have succeeded in a number of localities to prevent the spread of the disease. By the establishment of sanatoria, special hospitals, tuberculosis dispensaries, day camps, etc., we have succeeded in successfully treating and isolating thousands of patients. With this knowledge and experience before us I am free to confess that it has been a great surprise and disappointment to me that the Red Cross Society of this country has as yet done so little to imitate its German sister's magnificent antituberculosis crusade. I sincerely hope and pray that this great society will awaken to its oppor-

The cited enumeration of the activities, the membership, and wealth of the German Red Cross must have shown the vast field of usefulness to which our own glorious society could put its energy in

time of peace.

We have already the Washington Day Camp of the District of Columbia branch of the Red Cross. There is the Red Cross Day Camp of the New York State branch at Schenectady. The Albany subdivision has a capital of \$1,500, and plans for a camp are in formation. At this moment they are preparing a magnificent day camp on the roof of the Vanderbilt Clinic of the city of New York, and Dr. Samuel W. Lambert, the dean of the faculty of the Medical Department of Columbia University, informs me that it will be ready to receive patients on December 1st. The Buffalo subdivision of the Red Cross is helping in the maintenance of Dr. Pryor's Tuberculosis Day Camp, and the Delaware Red Cross branch is aiding the State's antituberculosis society in its dispensary work.

If you should ask me in what direction the American Red Cross could do most in the combat of tuberculosis at this time, I would say: First, it should join with the already existing local antituberculosis agencies, and by cooperating with them, learn of what there is the greatest local need. In some instances there may be urgent need of a hospital to take care of and isolate the seemingly hopeless cases; in others, a sanatorium for the early and curable cases; again, tuberculosis dispensaries may be needed to take care of the ambulant tuberculous patients; a day camp or perhaps a night camp may

be of urgent necessity.

To the best of my knowledge, the credit of the night camp idea belongs to Dr. William Charles White, medical director of the Tuberculosis League in Pittsburgh, who first proposed it to the profession. Of these latter institutions we have as yet but very few in this country; still it is my firm conviction that night camps do as much good as day camps. Many a tuberculous patient is obliged to work for his own maintenance or the support of his family. Upon the advice of his physician he may have changed his indoor occupation to an outdoor occupation, yet what good does it do him if he is obliged

to sleep in an unsanitary tenement or lodging house? And to what danger is not his family exposed when they are numerous and obliged to live

in close proximity with the sufferer?

I am convinced that the greatest number of infections originate in the sleeping rooms of our consumptive tenement house dwellers and at night time. It is then that the consumptive member of the family unconsciously expels the bacilliferous droplets during the cough which renders the atmosphere infectious. Fearing to have the other members of the family feel uncomfortable or cold, he will consent to have the windows closed at night, or close them himself in spite of the doctor's injunction to keep them open.

Through the night camp the family of the consumptive will be protected, and he himself assured of a good bed in a well aired room or shack.

When compared with other countries we are lacking most sadly in hospitals for tuberculous and scrofulous children. We physicians have felt for vears the need of seaside sanatoria, where the results of the treatment of tuberculous children are so splendid. In Charities of October 12, 1901, I suggested as a McKinley memorial a seaside sanatorium, with a pavilion for every State, for the treatment of children suffering from tuberculous and scrofulous diseases or predisposed to consumption. thinking that we could not possibly better honor the martyr President than by erecting to his memory life saving stations for children. There was some response to my appeal, but it has been left to the American National Red Cross to bring this matter before the public in a most practical way. After the example of the Delaware Red Cross branch, the American National Red Cross has decided to issue a beautiful stamp especially designed by Howard Pyle, the famous artist. It bears a wreath of holly, "Merry Christmas" and "Happy New Year." It will be on sale at the Red Cross headquarters in each State, and it probably can also be obtained from local dealers in almost every town after the 1st of November, 1908. It will be sold in sheets, like an ordinary stamp, and also in small books, nine for 10 cents, twenty-four for 25 cents, forty-eight for 50 cents, like the government stamps.

The Christmas stamp is not good for postage. It will not carry any kind of mail, but any kind of mail will carry it. Each one who uses this holiday stamp will help to "stamp out the white plague. It has been printed this time by the million to supply the demand, so any quantity can be ordered, but cash must be sent with each order, this rule having been followed last year with success. Nobody makes any profit on the Christmas stamp, but it was found last Christmas that every one was glad to help it along on these terms. For an order of one stamp or a thousand the price is the same, except in the little books, which add the cost of the binding, just as the government does. The proceeds in each State go toward tuberculosis work in that State, and particularly to tuberculosis work among children.

Thus, I believe my dream of 1901, of a tuberculosis sanatorium, with a pavilion for every State, may yet become true. Whether it will be named after McKinley or not may be immaterial to many, nevertheless, I believe to his many admirers this

might perhaps be an incentive to help. May I therefore be permitted to say in conclusion what I said just seven years ago, for the situation has not yet changed?

To realize the urgent need of seaside or inland sanatoria for children one must have visited the crowded tenement districts of our great cities and seen the large number of scrofulous and tuberculous children there, and the many who bear on their pale little faces the stamp of candidates for consumption

(pulmonary tuberculosis).

There are already laws in some States prohibiting the tuberculous child from attending public school; but as far as I know none of these States have provided other places where children suffering, it is true, from a chronic, communicable, but also curable disease can receive the education to which they are entitled, much less where they could have a chance of being cured from their affliction. The results obtained in some of our American sanatoria for the treatment of tuberculous adults are as good as any of those obtained in European institutions. The preventive measures inaugurated by our New York Board of Health have not only served as models for other American cities, but have been imitated by many European municipalities, and found to be the most practical and efficacious. We have already a number of sanatoria for the treatment of the consumptive poor adults, though by no means enough. However, in nearly every State of the Union the question of providing institutions for adult tuberculous patients with little or no means is now being agitated. Only for the countless little ones suffering from the same or other tuberculous diseases there is nothing done.

Our good McKinley had two children and these he lost. He dearly loved little children, and the creation of a sanatorium for the treatment and prevention of a disease with which so many American children are afflicted would surely be as fitting a memorial to this great man and lover of children as the monument of stone erected in Dayton. "McKinley Sanatorium for the Treatment and Prevention of Tuberculous Diseases in Children" should be the name of the institution suggested.

The meaning of the name William McKinley, written on the portals of these houses of hope for many a suffering mother's heart will be made clear to these little inmates by their teachers and grown

up friends.

In letting the children of parents of means who are happy and well bring their mites toward a movement of this kind, a lesson of charity and patriotism may be taught to them as well. There will be found in every community responsible and patriotic citizens to take this matter in hand and bring it to a successful issue. Let each State contribute enough to have its own pavilion to which to send its children. Let the Atlantic and Pacific coasts be dotted with such institutions, one or two pavilions for each State, according to its needs. Let good schools be attached to each sanatorium, so that the intellectual development of the children may not suffer.

The above described ingenious method of a Christmas stamp issued by the Red Cross will enable the poorest child to contribute toward the work. I believe it will appeal to poor and rich alike. To

cure the child of to-day means to save the community the expense of providing for the consump-

tive invalid of to-morrow.

While I believe that children's sanatoria are one of our most urgent needs, I by no means wish to underestimate the value of other means tending toward the eradication of tuberculosis as a disease of the masses. The decision of the Red Cross directors that the proceeds from the sale of Christmas stamps in each State shall go toward the tuberculosis work in that State is a most wise provision.

The National Red Cross brings this Christmas stamp to the whole nation this year. If each American man, woman and child buys one eighty million will be sold, and tuberculosis work from Maine to California will be reinforced and urged forward. The Red Cross is already an organized body; it has among its members the noblest, best and most patriotic of men and women. Surely, with such material, and the resources that are at its disposal, the Red Cross of America should become a mighty factor in the combat of tuberculosis and the eradication of the great white plague.

May the symbol of the Red Cross, which is international, join the double cross of the International Association for the Combat of Tuberculosis, and by their combined efforts help to subdue the greatest

enemy of human kind.

16 WEST NINETY-FIFTH STREET.

THE INTERNATIONAL CLASSIFICATION AS APPLIED TO MORBIDITY RETURNS.*

By Major Charles F. Mason, Medical Corps, U. S. Army, Washington, D. C.

Until 1805 the classification of diseases used by the Medical Department of the Army was based on that of the College of Physicians of England. In that year a new classification, devised by the surgeon general of the army, was adopted and used until 1904, when the International Classification of Causes of Death was adopted and has been in use ever since.

In his annual report for 1904 the surgeon general published the new classification, and said: "The old nomenclature was a thoroughly scientific one, but was not comparable with the International Classification of Causes of Death, which may now be properly regarded as the general system of the country, it having been adopted by the Census Office, by all the registration States, and by almost all of the registration cities for their local statistics.

"In the interests of uniformity, therefore, beginning with this year, army statistics will henceforth be based on the international classification; however, as morbidity as well as mortality statistics are compiled for the army, and as many diseases are encountered in the tropics which naturally are not classified separately under the international system; it has been found necessary to expand the detailed form of the census to meet army requirements."

In the Manual for the Medical Department, which is the official guide for medical officers, par.

427, are these instructions in regard to the use of the new classification for purposes of nomenclature: "Medical officers in recording the causes of admission to sick report will make use of the nomenclature given in paragraph 428 in all cases for which a specific title is provided. Experience has shown that it includes most of the causes of disability likely to occur in army practice. In recording cases for which a title is not specially provided, as, for instance, those which in a consolidation of the statistics would be tabulated under Mixed Infections and Other Dysenteries, or Other Epidemic Diseases, etc., such terms will be used as will briefly and accurately describe the disease or injury, while conforming as far as possible to the nomenclature generally accepted by the profession. Medical officers will report in this way also when the cases are to be consolidated on the classified list under a general term, as in certain of the diseases of the skin.

"(a) The organ or part affected should be specified when the name of the morbid condition fails to indicate it, as in paralysis, aneurysm, ulcer, herpes, etc., as also in inflammations, as adenitis, osteitis, arthritis, synovitis, etc., and in local injuries, as abrasions, burns, contusions, disloca-

tions, etc.

"(b) The surgical characteristics of wounds, fractures, hernia, etc., should be stated, and in all cases of poisoning the name of the poison should be given."

Since that time the classification has been modified slightly in detail from time to time, and the

latest form is shown in the table.

Of course army statistics deal only with adult males, so that all the diseases peculiar to women and children are omitted. Other titles omitted are scrofula, dropsy, and amputations, terms which are

not accepted as a diagnosis.

The following titles have been changed as indicated because the original terms are not accepted as diagnoses by this office: (4) Intermittent fever and malarial cacheria to malarial fevers; (9) diphtheria and croup to diphtheria: (22) malignant pustule to anthrax; (30) Potts disease; (31) cold abscess, abscess by congestion, and (32) white swelling consolidated as tuberculosis of the bones and joints; (120) Bright's disease to chronic nephritis.

Epidemic cerebrospinal meningitis (61) has been taken out of Class II, diseases of the nervous system, and placed in Class I, general diseases.

Inasmuch as the classification is used by the army for morbidity as well as mortality statistics, it has been necessary to considerably expand the detailed classification, but this has been done in such a way that the original international units can always be reconstituted; the number of titles has been about doubled and includes a good many tropical and other diseases which do not even appear in the index. Some of the titles have been duplicated, others subdivided; two series of numbers are used, those of the detailed international classification, and another consecutive series for each of the duplications or subdivisions.

Though of course some difficulties have been met with in the use of the classification for morbidity returns, on the whole it has proved its adaptability for such purposes in a very satisfactory manner.

^{&#}x27;Rear heavier the American Public Health As ociation at the meeting held in Winnipeg, Canada, August 25 to 28, 1908.

I.-GENERAL DISEASES.

To adapt the classification for morbidity uses I would suggest the changes shown in the accompanying list; these changes, except most of the duplications and subdivisions, are also suggested for

AT WHAT AGE PERIODS AND IN WHAT MEAS-URE HAS THE REDUCTION IN THE MOR-TALITY RATE FROM TUBERCULOSIS MANIFESTED ITSELF IN THE CITY OF NEW YORK DURING THE PAST FORTY YEARS?*

> By WILLIAM H. GUILFOY, M. D., New York,

Regular et Record , Department of Health, City of New York.

In studying the names given to the tuberculous causes of death of forty years ago we are struck with what appears to be an entire change of nomenclature when compared with the terms in vogue at

*Read before Section VI, International Congress on Tuberculors, Washington, D. C. Ostober 2, 1998.

the present day; phthisis pulmonalis has been superseded by pulmonary tuberculosis, hydrocephalus by tuberculosis of the meninges, tabes mesenterica by abdominal tuberculosis, psoas abscess and disease of spine by Pott's disease, hip joint disease by tuberculous hip joint disease; the only allied term that has held its own during all these years being scrofula; these changes indicative of infection by a specific agent and consequent upon the discovery by Koch of the tubercle bacillus, represent the establishment upon a firm basis of the recognized principles of preventive and curative ways and means employed in the extermination of this dread destroyer.

The late Dr. Elisha Harris, the first registrar of vital statistics of the Metropolitan Board of Health

of the City of New York, and one of the ablest and toremost pioneers in blazing out the paths to be followed in sanitary and statistical warfare—for in those days it was actual warfare—wrote into the pages of its third Annual Report, in 1868, the following sentences:

Hygienists now can measurably restrain and prevent the generation of this disease, which in our northern and middle States prematurely destroys from twenty to thirtyfive per cent. of all persons who pass the age of childhood, or from twelve to eighteen per cent, of the total at all ages; for, at least four of its factors of causation are now recognized in the list of avoidable conditions, to wit: 1, Wetness of grounds and habitation; 2, impurity of air and unwholesomeness of circumstances in indoor life; 3, defective sunlighting of dwellings; 4, needless exposure of nonconsumptive persons to the consumptive in unventilated places; avoidance of the contagious element in phthisis and of the circumsfances that render its contagious property operative. Even the hereditary constitutional perpetuating property of tuberculosis may year by year, and generation after generation, be diminished in the extent of its operation, for hygienic considerations should, and in a higher civilization will, favorably influence intelligent men in the selection of wives who are to be the mothers of their children; yet this may be the last in the series of preventive measures against phthisis; and, like the physiological requirements of hygienic alimentation, exercise, and sunlighting, the applications of hygiene to the hereditary improvement of the quality of our race will be attained only in a higher state of the popular intelligence.

The man who formulated such doctrine forty years ago could not but view with contented eyes, in the event of a visit as a reincarnated spirit to this hustling mundane sphere, the segregation of consumptives, the open air treatment, the avoidance of the infectious element, the sunlighting of dwellings, the establishment of parks, hygienic alimentation and sanitation, and last, but not least, the elevation of popular intelligence to a higher plane; the phrase "a higher civilization will favorably influence intelligent men in the selection of wives who are to be the mothers of their children" reveals us to-day in the position of "side stepping" this knotty problem. No small wonder then that the work of comparison of the statistics of the present day with those compiled under his supervision was simple in the ex-

The first striking feature of the reduction in the mortality rates is that at every age group in both males and females the proportion of decrease is considerable with the exception of the age group 45-55 in the males, in which the reduction is only one per cent., and the group 10-15 in the females, in which it reached the comparatively low mark of seven per cent., this latter explainable by the impaired general physical condition attendant upon the assumption of the generative function and thereby an increased liability to tuberculous infection.

The second feature of the decrease in the pulmonary tuberculosis rate is the greater decrease at all age groups among the females compared with those of the males, with the exception of the ages under five and between ten and fourteen; the reduction per cent. of the female mortality at all ages is fifty-five, and that of the males only twenty-nine, slightly more than one half that of the females. This is the more remarkable when we consider that of late years the female has taken up occupations classed as dangerous from an infectious standpoint,

such as those of typewriting, sales woman, flower making, feather working, etc. Why should the rate from this cause of death be almost fifty per cent. lower in the female sex than in the male? Exposure to the elements on the part of the latter has been offered as an explanation, and is true to some extent, as the death rate from pulmonary tuberculosis up to the twenty-fifth year is almost the same in the male as in the female, and at all ages above twenty-five the rate among males is greatly in ex-The abuse of alcohol is undoubtedly one of the potent factors in rendering the male more prone to infection and less amenable to recovery than the female; even the use of alcohol in the treatment of tuberculosis is being gradually discarded by the careful physician of to-day.

A third explanation of this phenomenon of the weaker sex surviving the stronger is that based upon anatomical and physiological difference of sex, the female by reason of the predominance of superior costal breathing more fully expands the apices of the lungs, and as tuberculous inflammation generally begins at the apices, consequently the natural physiological exercise of these parts militates against harboring of the bacillus tuberculosis

herein.

The table also shows that at the ages above sixty-five years in both sexes the reduction in the death rate has been greatest; that the age group at which the heaviest mortality prevails is that of 45-54 in males and both sexes combined, and 35-44 in females; that at the age group 45-54, seven males died to two females.

The assertion made as to the considerable reduction (forty-one per cent.) in the death rate from pulmonary tuberculosis at all ages, being one based upon the certification in early years of obscure pulmonary diseases as phthisis pulmonalis-the greater accuracy in diagnosis and certification of the present day serving to enter causes of death under their proper titles—are not capable of statistical proof; on the contrary, it is fair to assume that in the past if crude diagnoses placed doubtful pulmonary diseases under the heading "phthisis," thus transferring them from their proper heading from under "diseases of the respiratory organs," we should expect to find the death rates from the latter causes increased in harmony with the decrease from pulmonary tuberculosis. Such is not the case, however. Upon comparing the returns (see Table 2) for the years 1868 and 1907 we find that at those age groups at which the maximum number of deaths from pulmonary tuberculosis is reported, that is between fifteen and forty-five years, the death rate decreased forty per cent. in pulmonary tuberculosis, while that from diseases of the respiratory organs not only did not increase at the ages mentioned, but at these as well as at all ages showed a decrease of seven per cent. Again we must take into consideration that since influenza has become a factor in mortality tables, the deaths from respiratory diseases have increased considerably, and in the year 1907 this was especially true by reason of the severity of the epidemic; it may be argued that deaths which should have been entered as pulmonary tuberculosis in the year 1868 were credited to causes other than those of the respiratory organs,

as evidenced by the increased death rates from all causes at age groups forty-five years and over as shown in the table, but that argument may be met by a glance at the second table, which shows that the increase is due to the extraordinary rise in the death rates from circulatory, urinary, and cancerous diseases, and the moderate one in the rates from respiratory diseases at these age groups; the increased percentage in the death rate at ages forty-five years and over was 251 in circulatory, 153 in urinary, 124 in cancerous, and forty-three in respiratory diseases.

The death rate from other tuberculous diseases at all ages shows a much greater decrease than that from pulmonary tuberculosis, the percentage reduction being almost the same for males and females, seventy-eight against seventy-six, this equality in the decrease is all the more curious by reason of the large discrepancy in the reduction of the rate from pulmonary tuberculosis in the female compared with that in the male. The rates at age groups other than those under ten years should be disregarded by reason of the small number of deaths compared, especially those of the year 1868. Eighty per cent, of the deaths under ten years of age from other tuberculous diseases are reported as tuberculous meningitis, and it is likely that the decreased mortality from this cause is a real one, as the varieties of meningitis other than tuberculous show a considerable reduction in their death rates.

The death rates from all forms of tuberculosis show a considerable decrease at all ages, the reduction reaching forty-one per cent. among the males and sixty per cent. among the females, that of both

sexes being exactly fifty per cent.

The different age groups of the males show considerable decreases with the exception of that of 45-54 years, the increase being almost one per cent., which for all practical purposes may be disregarded; among the females the age group 10 to 14 years

shows an increase of fifteen per cent.

The third chart is based upon the absolute number of deaths reported in 1868 and 1907 from pulmonary tuberculosis, and shows the five age groups at which the highest mortality occurs arranged by sex and person in the order of their numerical supremacy. It shows that among the males the greatest number of deaths in 1868 occurred at the age group 25-34 years, and the second greatest number at 35-44, and then follows the groups 15-24 and 45-54; in the year 1907 the first two mentioned groups exchanged places, as did the second twoin other words, that there was a postponement of the fatal issue in many instances, a comparatively short one considering the intervening gap of forty years; among the females the age groups in question maintain the same position in 1907 as in 1868, that is, there has been apparently no lengthening of life among females suffering from this disease, in fact, the comparison of the ratios between the figures of alternate age groups for 1868 with those of 1907 warrants us in deducing that life has been shortened; as regards both sexes the age groups maintain the same position in 1907 as in 1868, but a study of the figures of both years justifies us in the conclusion that there is no shortening of the rluration of life. In order to ascertain whether these conclusions may be drawn calculations were

made as to the mean age at death from pulmonary tuberculosis of both sexes combined and males and females separately between the ages 15-64; admission is made that using this test as a measure of the duration of human life is open to serious objection, but the percentages of the age groups 15-64 of the entire population in 1907 are fairly identical with those of 1868—the percentages under fifteen years and over sixty-five years of the populations in 1868 and 1907 varying considerably; these latter age groups were therefore excluded—and as the results are used simply to corroborate deductions drawn from the table under consideration, we hold that the use of this test is allowable. The mean average age at death of males from this cause in 1868 was thirty-six years and three months, and in 1907, thirty-eight years and three months, an increase in length of life of two years; the mean average age at death of females from this cause in 1868 was thirty-six years and one month, and in 1907, thirty-three years and eight months, a shortening of the duration of life by one vear and five months; the figures for both sexes combined were thirty-six years and one month in 1868, and thirty-six years and nine months in 1907, an increase of eight months; from this we must infer that the prolongation of life in tuberculous patients has been on the whole comparatively meagre, that the male by reason of his preponderance over the female as to tuberculous infection and probably by the self sacrifice of his consort has received more attention at the hands of the public officials than the female, and in consequence the latter has not fared so well as to the added duration of life; it is true she has progressed further as to the diminution of the death rate at most age groups and at all ages, when compared with the male; she has probably sought medical aid earlier than the male in the commencement of the disease, and consequently more cases of complete cure are credited to her sex than to the The figures reiterate the necessity of early diagnosis and treatment, for without these the outlook for the eradication of tuberculosis is indeed

The brighter side of the question may be viewed from the standpoint that thousands of lives are saved yearly as shown by the decrease in the death rate at all ages. If the death rate at all ages of both sexes in the year 1868 is applied to the population of the present Boroughs of Manhattan and the Bronx, there would have been 10,190 deaths recorded from pulmonary tuberculosis against 6,030 actually recorded, a difference of 4,160; that coincident with the saving of lives there has been a saving in health to the community immeasurable in its value; another and darker view may be presented by the fact that during the past five years the death rate from tuberculosis has been almost at a standstill in the city of New York, and it seems to me that more drastic steps must be taken if we are to progress in our work; standing still is retrograding; the city, State, and nation must provide for the old, advanced cases for whom but slight provision has been made in the past and who undoubtedly are the chief factors in the dissemination of infection; when this duty is fully performed, and not until then, we may hope to see the arrival of the happy day when tuberculosis has disappeared from the civilized world.

TABLE I.

DEATHS AND RATES IN 1,000 AT DIFFERENT AGE PERIODS WITH INCREASE OR OPEREASE PYERCENTAGE FROM ALL CAUSES AND TUBERCULOUS RISEASES FOR THE YEARS SOS AND 1907.

OLD CITY (MANHATTAN AND BRONX).

A NEW METHOD FOR THE TRANSFUSION OF BLOOD.

152 WEST EIGHTY-FOURTH STREET.

An Experimental Study. (Preliminary Communication.)

By Robert T. Frank, A. M., M. D., New York,

Assistant Adjunct Gynæcologist, Mount Sinai Hospital.

(From the Pathological Laboratory, College of Physicians eni Sungeons, Columbia University.)

The experimental work embodied in this report was undertaken in order to secure a simple and rapid method of performing transfusion. The writer has been impressed with the technical difficulties encountered by several surgeons he has watched successfully and unsuccessfully attempting to transfuse. In every instance much delay and annoyance resulted during the freeing of the radial artery, the ligation of minute side branches, the stripping off of the adventitia, the introduction of three sutures (in the Crile method (1)), or the circular suture, when Carrel's (2) technique was employed. The exposure and preparation of the vein of the recipient was in every case easier than the manipulations needed for the artery, but even if the two vessels are laid bare by two operators, the time expended, the annoyance to both patients and operators, are not to be lightly regarded.

By my method all these annoying and at times fatal defects (i. e., fatal to the success of the anastomosis) are avoided, the entire procedure on the operating table being no more difficult than a

double infusion would be.

Instead of carefully dissecting out the artery of the donor and the vein of the recipient, cutting them across, and establishing an anastomosis by suture or some mechanical device, a bloodvessel obtained from an animal (a dog's carotid is convenient and is readily obtained), is prepared beforehand, and used for the connecting, vascular bridge.

Carrel (l. c.) and others have shown that heteroplastic vessels can be transplanted without causing clotting, therefore it was unnecessary for me to perform experiments to prove, that, for instance, the vessel obtained from a dog would not clot human blood during its short and rapid transit through the foreign artery. Nevertheless, to make assurance doubly sure, a rabbit's aorta used by me in a dog, produced no blood change, circulation being kept up for three quarters of an hour between the carotid and external jugular vein of the dog through the foreign bloodvessel. The blood current was stopped several times to facilitite coagulation, but none took place. The vessel, in this instance immersed in normal salt solution, had been kept in cold storage for seven days.

TECHNIQUE.

Preparation of the animal vessel.—A medium sized dog (fox terrier, for instance) is anæsthetized, and the entire neck region prepared for operation. A long median incision is made along the neck down to the trachea, extending to the sternum. The neck muscles on one side are drawn aside, when the vessels at once appear between trachea and muscles, only covered by a delicate sheath. With a small, blunt instrument the carotid artery is readily freed, and its lowest point ligated. The vessel is emptied of blood, by gently milking it upward between the fingers, until its facial branch is reached. An artery

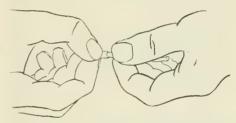

Fig. 1.—Stripping off adventitia. The left hand grasps the link with the pulp of the fingers, so as not to injure the intima. With the right the adventitia is stripped over the cut end of the vessel and then snipped off transversely.

forceps is then applied at this site, and the empty vessel cut across above the ligature and below the artery forceps.

The vessel thus obtained is at once plunged into a small basin of normal salt solution and again milked throughout its entire length, in order to remove any trace of blood before it has an opportunity to clot. The opposite carotid is obtained in an exactly similar fashion, and the dog killed by increasing the amount of anæsthetic. Possibly further experiments may show that a dog may be killed by anæsthesia and the vessel removed immediately after death without impairing the result.

We are now in possession of two vascular tubes of two and one half to three inches in length, without side branches, and of very elastic structure.

For the further preparations a set of Crile's or similar tubes (Ottenberg's (3), Buerger's (4), etc.), a pair of fine eye scissors, and two curved foreign body eye forceps are sufficient, though not indispensable. A spool of very fine silk, such as that used by Carrel, and a few very fine needles are also needed.

The *link* (as I will for the sake of brevity call the dog's carotid, which is to be used for the vascu-

lar bridge), is seized near one end, between two fingers, and the adventitia pulled beyond the inner thicker layers of the vessel, just as the foreskin is pulled over the glans during circumcision, and

Fig. 2—Passing the traction sutures. The left hand again grasps the vessel close to its end, the right passing the needle from within outward. Care must be exercised to include the intima.

snipped across where the vessel terminates (Fig. 1). The opposite end is similarly prepared.

Again taking up the vessel between the fingers, three fine silk sutures are passed approximately equidistant, from within outward, through the vessel coats, about one sixteenth to one eighth of an inch from the cut edge (Fig. 2). The sutures are tied so that each forms a traction loop. The entire manœuvre is surprisingly easy. The sutures are carried through the lumen of the Crile tube (the dog's carotid acts equally well if used on the largest or smallest size of the regular set) by means of a hypodermic wire, bent in the shape of a hook, the Crile tube steadied by the assistant, who also holds one suture, and by separating the three sutures the vessel is cuffed over the tube (Fig. 3) and secured by a fine silk ligature, tied in the upper groove.

The opposite end of the vessels is treated in the same way. The spare link may be prepared in the

ris "tuffing," the cannot The could be been drawn through the Crile tube. Vessel and tube are held in the assistant's left hand. The three sutures are separated to enlarge the lumen and remnt of culting

same way with smaller tubes in the event of some hitch or difficulty. Obtaining and preparing the links requires less than one half hour's time. If ob

If it further trial there often, I is proved unnecessary. The vessel is pushed through the tube and the edge seized at equidistant points with fine forceps instead of traction sutures.

tained aseptically and kept at 33° F. in normal salt solution, they can be preserved for at least one week.

Preparation of donor and recipient.—About one inch of the artery of the donor-in man the radial -is exposed under local infiltration anæsthesia, but no great care need be exercised in freeing the vessel from its sheath. A silk ligature is passed beneath the artery, but not tied. A vein, selected in the recipient, is laid bare in the same manner and a ligature passed. A serre-fine or Langenbeck hare lip clamp is placed at the central exposed portion of the artery and at the distal part of the vein to stop the circulation. The artery is now pulled out of the wound by means of the ligature, and with one snip of the scissors a small transverse slit made into its lumen. The edges of this slit are grasped on either side by the operator and his assistant with the curved eye forceps, and drawn apart. Through this aperture the one end of the cuffed link is intro-

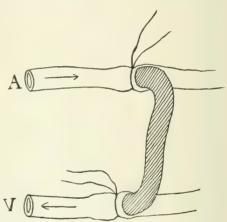

Fig. 4—Anastomosis established. Above is the artery of the donor, below the vein of the recipient. The link (shaded) has been introduced and secured in both vessels by ligature.

duced, toward the heart, and the silk ligature tied in the first or lower groove. The vein is treated similarly, and the opposite end of the cuffed link inserted toward the heart and secured in place by the ligature (Fig. 4). The serres-fines are now removed and the transfusion allowed to proceed. Throughout the manipulation both wounds should be kept well moistened with salt solution. While the transfusion is in progress the link must be supported by a gauze sponge, saturated in salt solution and covered by another moist compress.

After the exchange of blood has been effected, both artery and vein are tied off with catgut, above and below the small slit made, and the injured portion excised. The skin wound can then be closed by strapping or suturing.

The preparation of the link can be performed anywhere where aseptic procedure can be carried out. Before every transfusion time must be taken to determine whether the donor's blood does not act hæmolytically to that of the recipient—this determination must never be neglected. The actual introduction of the links is quite as simple as the in-

troduction of the so frequently used infusion cannula, and demands no greater technical skill.

The method here described has been tried only in animals, as no opportunity has so far presented itself to employ it in practice. The whole process, however, has proved itself so simple and easy of execution that I feel no hesitancy in presenting it to the profession for trial.

Further experiments are now in progress, looking to the more permanent preservation of the links. If these efforts should prove fruitful, it might be feasible to keep them on hand for an emergency, just as our suture material is now preserved.

In concluding this paper I desire to express my obligations to Dr. Baehr, of the house staff of Mount Sinai Hospital, who has assisted me throughout the experiments.

THE PUBLIC HEALTH PLANK. BY C. E. WOOD, M. D., Chicago,

United States Public Health and Marine Hospital Service.

In this age of impetuosity and enthusiasm, the people, including those individuals who frame the representative platforms of the political parties, frequently propose to do things for the general welfare without considering the means available and how they can legally be utilized.

First-The proposition, in short, is to create a Public Health Department with a cabinet officer to look after all the government affairs concerning the public health. This sounds as if heretofore the government had absolutely neglected the public health.

whereas such is not the case.

Secondly-How can this be accomplished? But before we take up the matter of accomplishing something it is well to consider what "all the government affairs concerning the public health' means. Some would include certain features of the Department of Commerce and Labor, such as the work carried on in examining foodstuffs for adulterations, which only incidentally bears any relation to health, and is primarily intended merely to protect merchants from unfair competition. would include the work carried on by veterinary surgeons, inspection of meat for export, another purely commercial problem devised to meet the requirements of foreign countries, where our meat will not be accepted without the government guarantee. In this connection it is interesting to note that meat that is used in a State where the animal is killed is not required to be inspected, but only when shipped from one State to another. Of course these investigations have to be made and are indirectly in relation to the public health, but it is a lamentable fact that the inspection of meat before it is consumed in the locality in which it is killed is in no way covered by the United States laws. There is a way to further protect the public health. which has already been endorsed by the leading medical societies, medical journals, etc., as well as by the United States Senate. I refer to the plan suggested by Mr. Hepburn in his bill, which has passed the United States Senate, and is now pending before the House of Representatives. He proposes to further protect the public health by imposing additional duties on the Public Health and Marine Hospital Service. To many people the mention of this service brings up an image of some antediluvian hospital building on one of the inland lakes or rivers, and they do not see the connection between this image and the public health. To those sections where there have been recent outbreaks of vellow fever or plague, when they have been in greatest need, the Public Health and Marine Hospital Service has a deeper significance. In order to give a more accurate account of what the government is really doing to protect the public health I quote from the address of Surgeon G. B. Young, United States Public Health and Marine Hospital Service, delivered recently before the Chicago Medical Society.

THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE. WHAT IT IS AND WHAT IT DOES.

While doubtless much of my subject matter is familiar to the members of this society, still the rapidly expanding functions of the Service which I have the honor to represent, and the fact that some at least of our members may not be entirely familiar with the history of its origin, and the scope of its activities, has prompted me to present a brief résumé of the subject

General History.—Organized in 1797 the Service has had an existence but little shorter than that of the nation itself, and a most interesting history, but on the greater part of this there is not time to enter; I will therefore content myself with the briefest possible outline of all but the most

recent period.

Originally this Service was intended to provide for the medical and surgical care of both the merchant and naval seamen. The organization was without much uniformity of administration in the earlier years, was supported by a small sum deducted from the wages of such seamen, was, as it has remained, under the supervisory control of the Secretary of the Treasury, and had as medical officers physicians who were appointed for local duty at various rates of compensation, and usually selected for political considerations.

In 1811 the Naval Hospital Service was given an estab-

lishment of its own.

The original Service gradually expanded in usefulness and increased in efficiency, but the organization remained practically unchanged until 1871, when it was reorganized, given a chief with the title of supervising surgeon, made subject to a formal set of regulations of universal applica-tion, and fairly started on its very remarkable career of

expansion and usefulness.

In 1873 competitive examinations for admission to the Service were instituted, and in the next few years the personnel was arranged in the three grades of assistant surgeon, passed assistant surgeon, and surgeon, and underwent a pretty complete metamorphosis, the old, local, politwent a pretty complete metamorphosis, the old, local, political appointees being gradually eliminated and going out very rapidly when regulations were made that officers should be subject to periodical change of station.

In 1889 the officers of the corps were given commissions, and placed upon the same general footing as medical officers of the army and navy.

In 1902 the increasing importance of the sanitary work of the Service lead to the enactment of a law changing the name to the Public Health and Marine Hospital Service The time allowed me does not provide for even a hurried review of the various steps by which the Service has grown to its present importance in the work of national sanitation, I can only state that the first important step was taken when the Service was given charge of the few national quarantine stations then existing. This was in 1883.

At the present time the Service consists of 129 commissioned officers, three chiefs of divisions in the hygienic laboratory, three sanitary inspectors, 237 acting assistant surgeons, forty-five pharmacists, and 831 employees. It has a fleet consisting of nine steamers and tugs, nine steam launches, seventeen naphtha and gasoline launches, and eight barges, in connection with which it has thirteen pilots and twenty marine engineers, besides the other members of the crews.

So much for what the Service is, now for what it does Under this head it seems best to first outline the duties of the Service, and then give illustration of the extent to which it has justified its existence, by the manner in which it has performed these duties. In other words, to first enumerate the things it is expected to do, and then give a few illustrations of the thoroughness with which it has

done them.

On the hospital side of the Service it provides hospital and out patient relief for merchant seamen, for the officers and men of the Revenue Cutter Service, the men of the vessels of the Light House Service, the life saving crews, the employees of the Mississippi River Commission, the crews of the vessels of the United States Army engineers engaged in river and harbor work; to foreign seamen on application of the proper authorities, and the officers and men of the army and navy when the accommodations of their services are not available. It maintains for this purpose twentyone hospitals, thirteen stations at which patients are cared for in civil hospitals under care of a commissioned medical officer, and a large number of minor relief stations. Service also furnishes medical officers for a number of the large, sea going revenue cutters.

During 1007 it treated 14,068 patients in hospital, and 40,-

161 out patients.

The next group of duties is roughly embraced under the classification of assistance rendered to various departments of the government. These include the examination for color blindness and general visual acuteness of all the candidates' for license as pilots, masters, and mates; the physical examination of men enlisted in the Revenue Cutter Service, the life saving crews, etc. In the performance of these duties the Service last year made 5,205 physical examinations.

All the immigrants arriving in this country are inspected by the Service to determine if they are suffering from contagious or loathsome diseases, or have disabilities liable to render them public charges. Of these we last year examined 1,285,349 persons, and cared for large numbers tem-

porarily detained in hospital.

I come now to an enumeration of the duties appertaining to the public health work of the Service. We examine the products of every firm or institution engaged in the manufacture of any and every kind of antitoxine, vaccine, and similar substances, and none of them can legally dispose of their output by interstate commerce without receiving our

license to do so.

We conduct a large and splendidly equipped hygienic laboratory in Washington wherein the officers of the Service and the health officers of States and municipalities can receive instruction; wherein extensive investigations in chemistry, pharmacology, parasitology, bacteriology, and practical sanitation are conducted; from which issue a large number of valuable pamphlets and monographs; and whence officers are sent to make studies of local epidemics, and special researches, as of spotted fever, hook worm discase, meningitis, and the like.

I am sure it will be a surprise to many of our members to learn that in connection with these sanitary and bacteriological investigations and exclusive of the officers permanogical investigations and exclusive of the onicers behinden neutly detailed to the Philippines, Cuba, Puerto Rico, Pan-ama, Hawaii, the Service now has officers detailed at Cal-cutta, Hong Kong, Nagasaki, Yokohama, Naples, Guaya-quil, Callao, La Guayra, and Rio Janeiro.

In this connection also it should be mentioned that we are prosecuting an elaborate study of leprosy at the Molokat Leprosy Settlement in the Hawaiian Islands, that a hospital and laboratory of the most modern type are being erected there at a cost of \$100,000, and that we have an annual appropriation of \$50,000 for the prosecution of these re-searches. I would like to go still farther into the work along this and similar important lines, but a mere enumera-tion would take too much time. One phase of our hospital work, however, merits especial mention, since it was the pioneer work of the sort in this country. I allude to the Sanatorium for Tuberculosis which is maintained by the Service at Fort Stanton, New

As far back as 1893, fully five years before any steps had been taken in this country to inaugurate national or State sanitation for tuberculosis, and nearly ten years before the great antituberculosis fight of the present day had been great antituderculosis fight of the present day had been begun, the initial gun in our campaign had been fired. I quote from the article by Passed Assistant Surgeon J. O. Cobb in the Service Report for 1893: "The great number of tuberculous cases demands some prompt action by the Government to relieve the hospitals, as well as to move the patients to a locality favorable for their recovery. The general hospital is not the proper place to treat these patients, even though there were room enough to isolate them. For climatic conditions also the various hospitals situated in different parts of the country are not conducive to the com-fort or eventual recovery of these cases. As an actual fact nearly all seamen with tuberculosis of the lungs die. These cases are discouraging to treat even in an equable climate, but far more so when the climatic conditions are more unfavorable, and nearly every station in the Service is unfavorably situated in this respect. To emphasize the fact of the great fatality of the disease more strongly, take the Service statistics for an average year, say, 1890, and we find that 756 patients of tuberculosis were treated; two recovered (the two recovered were cases of local tuberculosis), 327 improved, 113 died (20 per cent.), 86 being on hand at the end of the fiscal year. That is a large percentage of deaths, too large; and these statistics are even then unreliable to this extent: Many of the patients re-ported as 'improved' finally return or go elsewhere, and are recorded as new patients, while, in fact, they are old ones. The same patient goes out 'improved,' tries to work, gets worse, goes into another hospital, is reported as a new case, possibly goes out again as 'improved,' and so on until tast, possibly goes but again as improved, and so on the finally dies. This is the average history of the consumptive patient. I should say that, taking into consideration this fact, the percentage of deaths yearly is nearer thirty-five than twenty per cent. My experience has been that nearly all of these patients die in hospitals finally." Dr. Cobb proceeded to urge the establishment of two sanatoria for the segregation of the tuberculous among our patients. In 1895 Passed Assistant Surgeon Bratten, who a little later lost his life on quarantine duty, one of the number of officers who have given up their lives on the altar of preventive medicine, wrote an able article from which I quote as follows, pages 154, 155, 156: "In 1896 the surgeon general urged the importance of the proposed plan, and, in aid of it, began a systematic investigation of the laws or regulations of States on the subject of tuberculosis. He kept up the fight unsuccessfully until in 1899 he obtained the use of the abandoned military reservation at Fort Stanton, New Mexico, where the first great governmental sanatorium for tuberculosis was established, at which the average number of patients on hand is about 200." Passing now to a statement of some of the many other instances in which the Service has demonstrated its capacity for efficiently discharging the duties entrusted to it, I invite attention to the fact that, within a few weeks of the first announcement by Professor Koch of the discovery of tuberculin, Assistant Surgeon Geddings was sent to Berlin, and, by arrangement, made through the Department of State, was permitted to enter the professor's laboratory and study his methods; and that as early as January 2, 1891, the systematic investigation of the new treatment was inaugurated by the Service, the first work of the kind undertaken by any State or national agency in this

Again: In the preparation of diphtheria antitoxine the Service was the pioneer in this country. Roux read his epoch making paper before the International Congress of Hygiene and Dermography at Buda-Pest in September, 1894. Passed Assistant Surgeon Kinyoun was our delegate at this conference, and by September 20th the surgeon general had him at work under Professor Roux in the Institut Pasteur, and thence he went to the laboratory of Professor Behring to still further pursue his studies.

On November 9, 1899, the production of diphtheria antitoxine from toxine forwarded by Dr. Kinyoun was commenced in Washington under the charge of Passed Assistant Surgeon Geddings, the work being intended not only to give an immediate supply of antitoxine for use of the Service, but to afford instruction to State and municipal health

officers in the methods of production.

cannot even enumerate the important achievements of the hygienic laboratory in the fields of bacteriology, parasitology, disinfection, and sanitation; the researches into plague, yellow fever, typhoid, and tuberculosis, but will content myself with a brief mention of two instances of the greatest importance from both the sanitary and economic points of view.

The first relates to the work of Professor Stiles in this country, and Passed Assistant Surgeon King in Puerto Rico

on uncinariasis.

The former has conclusively demonstrated that the anæmia, malnutrition, marked indisposition for sustained exertion, and resultant social condition, usually described as which has characterized large numbers of "shiftlessness," which has characterized large numbers of the poorer class of rural whites in the South, are due to a widespread infection with the Uncinaria americana, or

hookworm.

It is difficult to exaggerate the sociological and economic importance of this discovery. Here is a group of at least five great States in which the rapidly extending industrial and agricultural development has been seriously handi-capped by the relative inefficiency of the local white labor supply, an inefficiency now demonstrated to be largely due supply, an inemercency now dentificated to be largely due to an adventitious and removable cause, while the work of the Puerto Rico Anæmia Commission, headed by Passed Assistant Surgeon King, of our Service, and Captain Asiford, of the Army Medical Corps, has demonstrated almost certainly the steps necessary to prevent infection, and quite certainly the possibility of the complete cure of the disease

certainy the possibility for the compared card among a generally infected population.

The second notable work is the recent systematic and extensive research into the milk problem. I cannot take time to indicate the scope of this great work, but its results as embodied in the Bulletin of the Hygienic Laboratory, No. 41, a volume of 750 pages, is the most systematic, complete, and important exposition of the subject of which I

have knowledge.

I come now to a brief history of the development and results of the Service control of the national maritime

quarantine.

This was practically the first public health work undertaken by the Service, and, as a result there are hundreds of people in our profession, and tens of thousands of laymen who have never gotten rid of the idea that the Service activities are practically confined to this kind of public

health work.

We began in 1883 by taking charge of two or three rudimentary sort of quarantine stations on the Southern coast. We found that the procedures of that time were probably as good as those in most parts of the world, but still little advanced beyond the standard of a century before. In the earlier years the Service had to contend with the active opposition of the State stations, an opposition born in part of the antagonisms of the local officials, who saw their occu-

pation endangered, but arising for the most part from a profound and honest mistrust of our ability to do the work. We had to justify our existence, and the history of those earlier years, when Carter and White, Murray, Guiteras, and the others were struggling to make bricks without

straw, would make an interesting story.

We developed a system of maritime quarantine, inventing machinery, originating methods, perfecting organization, until it has become the recognized standard of the world.

In the face of active opposition from many for whose protection our officers gave years of unceasing labor, and not a few sacrificed their lives, almost unknown to the profession at large, amid unceasing difficulties, the work went on until recognition born of sheer efficiency caused State after State, and port after port, to trust us for their protection; until at the present time, the entire Pacific coast is in our keeping, and only three States on the whole Atlantic and Gulf seaboard, namely, Massachusetts, New York, and Texas, are not covered by stations either operated directly by our Service, or under its supervision.

With the development of national expansion which followed the Spanish war the maritime quarantine responsibilities enormously increased. We took charge of the coasts of Cuba, Puerto Rico, the Sandwich Islands, and the Philippines. The former control ceased with the establishment of the Cuban Republic, but the work in the other countries

has steadily grown in scope and effectiveness

The work of Glennan and Lavender during the transition after the war in Puerto Rico, that of Cofer during the plague in Honolulu, and the enormous task successfully achieved by Perry in the Philippines during the Aguinaldo war and the troubled years following it, presents a succession of most brilliant achievements.

If proof was needed it is found in the facts that the territorial government of the Hawaiian Islands has made Passed Assistant Surgeon Cofer the president of the Terrirassistant Singeot Coler in presents of the Fernandian torial Board of Health, and placed him in charge of all the sanitary work of the islands; that at the request of the government of Ecuador Passed Assistant Surgeon Lloyd has been made chairman of the commission created to fight the plague in that country; that at the request of the government of Guatemala, Surgeon White has been detailed to consult with that government as to the sanitation of its ports, and that for several years past all public health work, botts, and that for several years past an public leafth work, state, and municipal, of the entire Philippine Archipelago has been placed in charge of Passed Assistant Surgeon Heiser, who combines the offices of chief quarantine officer with that of director of health for the Philippines.

An important and interesting phase of this work concerns the provisions for safeguarding against danger from yellow fever the commerce with Mexico and the Central American

states.

To do this we keep representatives in Belize, British Honduras; Ceiba, Honduras; Puerto Cortez, Honduras; Bluc-fields, Nicaragua; Coatzacoalcos, Mexico; Vera Cruz, Mex-ico; Progreso, Mexico; Livingston, Guatemala; and Port Limon, Costa Rica.

In this connection also belongs mention of the work of

the Service on the Isthmus.

When Colonel Gorgas assumed control of the sanitation of the Isthmus the task of preventing the introduction of or the Islamus the task of preventing the introduction of infection by the thousands of laborers brought from the West Indies and elsewhere was entrusted by him to Surgeon Carter, of the Public Health and Marine Hospital Service, with Passed Assistant Surgeon Perry and others as assistants. At the same time officers were stationed at Barbadoes, etc., to insure a supervision of the sources of labor supply. The Service thus being given the task of labor supply. holding the door until Colonel Gorgas could clean house.

Subsequently this work was placed under the command of Passed Assistant Surgeon Perry, and Surgeon Carter assumed and retains the post of director of hospitals, in which capacity he has charge of all the hospitals on the

I pass in conclusion to the work the Service has done in preventing and controlling epidemics of smallpox, yellow fever, cholera, and plague.

It would take a not inconsiderable volume to adequately describe this work. I must content myself with a mere mention of a few conspicuous instances, omitting entirely

the work in Honolulu and the Philippines.

In the case of smallpox I cannot even take time to touch upon the subject, extensive as the work formerly was, for the Service now considers that, outside of maritime quarantine, smallpox is negligible in an epidemicological sense, antine, smarpox is negligible in an epidemicological sense, holding that no individual and no community need have smallpox unless he or it deliberately chooses to do so.

Of yellow fever we have successfully handled seven epi-

demics in the past twenty years, besides a number of local

outbreaks of larger or smaller importance.

I do not mean that all the work in these epidemics was done by the Service, but that, as far as the laws gave us an opportunity, we have handled the work and done it

successfully.

Still, in 1893, we practically handled all of it, in 1897 much of the interstate work and much of the local work, in 1898 the same; at Laredo, two years, practically all of it, and in 1905, much of the interstate work and most of the local work, either directly, as in Lake Providence, Natchez, and New Orleans, or partially, as in Vicksburg, Gulfport.

I regret I cannot relate the work of Carter, Cobb, Murray, Geddings, and others, in prior years, but will confine

myself to 1905.

In that year, for example, we absolutely controlled the interstate movement of all passengers and freight in Mississippi, western Tennessee, extreme western Kentucky. southeastern Tennessee, and a considerable portion of Louisiana, and from Georgia to Florida supervising the entire passenger movement over about 2,500 miles of nine rail-roads, which ran from, through, or communicated with,

infected territory, for over three months, without a single case of vellow fever being imported by railway into the ter-

ritory controlled.

Wasdin on the coast, Krauss at Lake Providence, von Ezdorf at Talulla, Guiteras at Vicksburg, in the face of stupid and selfish opposition, did brilliant work; Lavender at Natchez conducted a really notable and memorably successful campaign, and White made a record in New Orleans and vicinity that has been seldom equalled and never excelled in the history of medicine.

Consider this last: Here was a city of 325,000 people,

filled with nonimmunes, swarming with infectible mosqui-toes; with miles of open gutters little better than ditches, with thousands of homes surrounded by dense vegetation, and dotted over with ten thousand of above ground cisterns and other stegomya breeding places. In this city there had occurred about 600 cases of yellow fever prior to the assumption of control by the Service, about 200 of which were then in existence. Surely a task of such magnitude

was enough to dismay even the most sanguine.
Some twenty commissioned officers, several of whom subsequently contracted the fever, were detailed to Surgeon White, about fifty acting assistant surgeons were selected and appointed for the same duty, and an army of nearly 1,400 men employed and assigned to various tasks.

Speedily the disease was checked, soon it was controlled, and long before the occurrence of the frost, which had the disease, the great task was ended, and the president of the United States could in safety make his promised

October visit to the city.

In the case of cholera, the preventive work of the Service was no less successful. In 1893 cholera was widespread in most of the territory, and epidemic in some of the ports from which our immigrants come. We stationed officers and organized preventive work, isolation, detention, disinfection at Glasgow, Southampton, Havre, Amsterdam, Bremen, Rotterdam, Hamburg, Marseilles, Genoa, and Naples. In two instances cholera reached our shores under circumstances beyond the control of the Service, but even then we were able to forewarn the authorities on this side of what was coming, and forearm them for their tasks. Where the responsibility was really ours we handled scores of ships and tens of thousands of persons from infected localities, and not one single case of cholera oc-

Now was this a series of fortunate accidents? It happened that in one case we had a control experiment. Side by side with the ships leaving Naples for this country there sailed ships bound for South America. The water was the same, the food of the same character, the people drawn from the same villages, and transported alike, until at Naples, ships and people destined for this country passed into our

Every ship we did not handle became a floating charnel house, one losing 200 of its passengers. On those we did

handle there was not one case of cholera.

The fight with plague began in 1900, when Surgeon Kin-youn announced its presence in San Francisco. Vilified, abused, insulted, arrested on frivolous charges, even his life threatened, he stood to his guns until at length the truth could be no longer denied, and finally the aid of the Service was invoked, and in 1904 the disease eradicated for the time.

In the month of May, 1907, a sailor from a local vessel was admitted to the United States Marine Hospital at San Francisco and vicinity; later two cases occurred in

Under arrangement similar to that made in New Orleans the Service assumed charge of the situation, detailing Passed Assistant Surgeon Blue in command, with numerous assistants, establishing a well equipped laboratory. have been no cases since January 30th, but the sanitary campaign and the hunt for infected rats still goes on with tan band of wigor, and we have good ground for hoping that the Service will score another signal triumph.

I am aware that I may be charged with having written in a somewhat boastful spirit. My reply is, that, if I have be tool, the telescent of concernation of the second of the se

been to state the facts to the society to the end that it might see how the Service had acquitted itself of its trust.

If to do this seems boastful it is the facts that boast, and not their narration.

Like every governmental service, from the postal service down, the rise of the Public Health and Marine Hospital Service to its present state of efficiency has met with a considerable amount of opposition. For many years almost every legislature has been beset with men outside the service who in most instances for selfish motives have endeavored to do away with civil service regulations and create some new system of conducting the business of the government, and almost always part of the programme for the general welfare is that these individuals are to hold lucrative positions.

In many instances these men were informed as to the scope of the work done in this branch of the Treasury Department and would like to have had a share in the glory of the men who have devoted their lives against colossal prejudice, born of ignorance, superstition, or jealousy, to bring the Service

up to its present state of efficiency.

So high is this Service regarded in foreign countries that the vounger officers are frequently astonished by the magnitude of respect and deference shown them while on foreign duty. The care exercised in preventing the departure of passengers for the United States afflicted with communicable diseases is highly appreciated by foreign peoples, and would be more appreciated by the American public if their attention was as frequently called to

the subject.

The recent handling of epidemics by this Service has brought it into the limelight, and much more is expected of it than formerly by the general public, which applies to this Service for all kinds of unauthorized relief and advice. In handling an epidemic it is too much to expect a poorly paid practitioner to report the first case he has had perhaps for weeks, when his living depends not on the prevention, but on the cure of disease. Some men may report the first case they see, but in the investigations at New Orleans and other places it was found that some physicians were, to say the least, a little tardy in reporting the presence of yellow fever. The average American physician rises to meet emergencies and meets them well, and in certain instances epidemics have been suppressed by individuals. In the case of late epidemics the concerted action of the men of the Public Health and Madine Hospital Service, trained for epidemic duty, empowered by the United States Government, and sworn to protect the constitution, working in harmony with the best men available in the affected locality, has been proved to be a most efficient and successful way of fighting epidemics.

The work has recently been endorsed by the American Public Health Association and other great medical organizations as well as by the United States Senate, which voices the sentiment of a large part of the enlightened and unprejudiced public. Great strides have been made, and the public mind is turning to read the truth. It is not stronge that at this period of the awakening of the body politic a few men more gifted as politicians than as scientists should rise and enlist their standard bearers and move on to Washington, hoping to shatter the

constitution by shouting their self praises from the house tops, and to inaugurate a new régime better calculated to meet their own selfish interests than to serve the public.

Mr. Hepburn's bill is as follows:

Sixtieth Congress, first session. H. R. 18.792.

IN THE HOUSE OF REPRESENTATIVES.

MARCH 6, 1908.

Mr. Hepburn introduced the following bill; which was referred to the Committee on Interstate and Foreign Commerce and ordered to be printed.

To further protect the public health, and imposing additional duties upon the Public Health and Marine Hospital Service

Be it enacted by the Senate and House of Representa-tives of the United States of America in Congress assembled. That in addition to the laboratory investigations now authorized by law of infectious and contagious diseases, the surgeon general of the Public Health and Marine Hospital Service, with the approval of the secretary of the Treasury, shall from time to time make special investiga-tions into the prevalence of tuberculosis, typhoid fever, rabies, and other diseases affecting man, the conditions in fluencing their propagation and spread, and methods necessary for their prevention and suppression. These investi gations shall include housing, occupation, and disposal of wastes, as they affect the public health. The investiga-tion of rabies shall include the preparation and use of the virus or other substance made in the hygienic laboratory for its prevention in those exposed. He is further authorized, on request of the health authorities of a State, Territory, or the District of Columbia to detail officers to cooperate with said authorities in their measures for the protection of the public health.

Sec. 2. That the results of the investigations authorized

in section one of this Act shall be published in the discre-tion of the secretary of the Treasury, and there shall also be disseminated by means of sanitary bulletins and exhibits practical information concerning the prevention or sup-pression of tuberculosis, typhoid fever, and other diseases pertaining to man, and the surgeon general shall prepare and distribute said bulletins. He shall also cooperate with the trustees of the United States Pharmacopeaa and pre-pare and publish, with the approval of the secretary of the Treasury, digests embodying the results of investigations

for use in revision of said pharmacopæia. Sec. 3. That to facilitate cooperation between State and Sec. 3. That to facilitate cooperation between State and territorial boards of health or departments of health, including the District of Columbia, and the Public Health and Marine Hospital Service, there shall be established a school hygiene for which the facilities of the hygienic laboratory shall be available. Regulations for admission to and for the conduct of said school shall be made by the surgeon general with the approval of the secretary of the Treasury. There shall be received in this school, with such limitations as may be deemed processary. State county and limitations as may be deemed necessary, State, county, and numications as may be deemed necessary, State, county, and municipal health officials, on application by the board of health or health department of any State, Territory, or the District of Columbia: Provided, That satisfactory assurance is given with the application and by the health officer himself that the special instruction desired is to be utilized in the performance of official health duties. Officers of the Public Health and Maying Health Service shell be de-Public Health and Marine Hospital Service shall be de-tailed as instructors in said school, and officers of said Service may also be detailed to receive instruction. An official, upon satisfactory completion of the course of study in sanitary science as prescribed in the regulations, shall

In sanitary science as presented in the top to be entitled to a certificate to that effect.

Sec. 4. That the bureau division of domestic quarantine and the bureau division of foreign and insular quarantine are hereby consolidated into one division, to be known as the beauty of the section so the section so the section so the section section. the division of quarantine, and there is hereby established a bureau division of water supplies and sewerage. Each of these divisions shall be in charge of a commissioned medical officer of the Service detailed and designated for that purpose, who, while thus serving, shall be an assistant surgeon

general, as now provided by law for the medical officers in charge of the remaining divisions of the bureau; and it shall be the duty of the surgeon general, under direction of the secretary of the Treasury, to investigate the pollution of interstate waters as it affects the public health and make report upon the methods necessary to prevent said pollution, with recommendation as to necessary legislation relating thereto. For this and other purposes there shall be appointed by the secretary of the Treasury, on recommendation of the surgeon general, a sanitary engineer competent to solve technical problems connected with the puribe fixed by the surgeon general, with the approval of the secretary of the Treasury, and not to exceed five thousand dollars per annum. There shall also be appointed in like manner a solicitor of the Public Health and Marine Hospital Service, who shall be familiar with the public health laws of the national government, States, and municipalities, taws of the haddrag government, States, and municipantics to aid in establishing uniform measures for the protection of the public health, and to perform such service of a legal nature as may be required. The salary of the solicitor shall be fixed by the surgeon general, with the approval of the secretary of the Treasury, and shall not exceed five thousand follows for several solicitors and solicitors are several solicitors and solicitors are several solicitors and solicitors are several solicitors. sand dollars per annum.

Sec. 5. That in addition to the conferences now authorized by law to be held between the surgeon general of the Public Health and Marine Hospital Service and the health authorities of the States, Territories, and the District of Columbia, when in the opinion of the surgeon general it is in the interest of the public health to call a special conference, to be held in Washington, of said health authorities of not more than five States and only one from each State, the said delegates shall receive a compensation of ten dollars a day, including the days of travel to and from Washington and necessary traveling expenses: Provided That not more than five such conferences shall be held in any one year and the duration of any such conference in Washing-ton shall not exceed three days. The five members of the advisory board of the hygienic laboratory now entitled by law to receive compensation when called in conference shall hereafter receive a compensation of twenty dollars a day, including the days of travel to and from Washington by the shortest practicable route, together with necessary traveling expenses: Provided, That the said advisory board, in addition to its duties as now defined by law, shall, while in conference, consult and advise with the surgeon general with respect to scientific matters relating to the public

The advantages of this bill are many. Not the least of these is the fact that it makes use of a highly organized aggregation of men already trained and experienced in public health work. By means of judicious expansion of this bureau every need of a public health department can be met.

Metallic and Magnetic, Physical and Philosophical; Its Place in Mythology, in Demonology, in Astrology. and in Medical and Surgical Therapeusis.

By John Knott, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A., Etc., Dublin, Ireland.

(Concluded from page 028.)

It was by Monardes of Seville (in 1571) that some rational instructions regarding the internal administration of iron were published for the first time, so far as our extant medical annals now bear testimony. The principal conclusions which this iatrochemical pioneer derived from his own experience and observation in this connection were, that it improved the appetite, increased the bodily (muscular) vigor, diminished the volume of the spleen, and cured impotence. This collective accomplishment of so many of the most important feats of therapeusis represented the execution of "a very

large order," indeed; and in one of the most im- tial preparations. There are no less than half a portant departments of the Æsculapian shrine. And on the basis so founded, the clinical claims of the items of the "martial" armamentarium were allowed, almost continuously, to rest for over another century. And the persistent survival of the reputation of iron as a genital stimulant, from the date of the oldest recorded case of its internal administration down to the present day, might almost seem to justify the speculative surmise of the Galenic commentator who professed to regard the Græco-Roman tradition of the loves of Mars and Venus as a parabolic version of certain supremely important natural facts; masking, so as to conceal from the vision (and discussion) of the profane, the esoteric revelation of the potency of the properties of iron in promoting the functional powers of the sexual

The modern history of the clinical employment of the compounds of this-so generally usefulmetallic element may be said to date from its advocacy by the "English Hippocrates" in the treatment of chlorosis. Thomas Sydenham, the "Father of Modern Clinical Medicine," thereby laid the solid ("experimental" or "empirical") basis of the reputation of "ferruginous" preparations in the regeneration and reconstitution of the vital fluid within the human body. And ever since that date (1681) the therapeutic fame of "martial" remedies-in the special department of hæmatogenesis-may be said to have waxed in strength and stature (even if not invariably so in wisdom). Sooth to say, indeed, the chlorotic theory of the great English physician was not a very illuminating one-regarding, as he did, the "green sickness" as a species of hysteria (af-fectionis hystericæ); but it is only just to add that even the scientific clinician of our own day can afford to regard the haziness of his intellectual vision with sympathetic toleration, as the respective microbes of both chlorosis and hysteria seem to have hitherto successfully eluded the research of the most accomplished and enthusiastic bacteriological pathologists.

An instructive—and often very impressive—mental picture of martial therapeutics (as well as chemistry and pharmacology) may be derived from a persual of The New London Dispensatory (1676) of the then famous herbalist, William Salmon. We there find a series of thirty-one preparations of iron. The author begins at the beginning by "the purifying," and tells us that "iron well purified is then chalybs or steel; and therefore since steel is nothing but purified iron, it is far better than iron for any medicinal use." And his instructions for the process are: "R. Iron plates or bars, p.j., beech coals powdred, shavings of oxhorn, ana p.j., lay them stratum super stratum, put them into a close vessel in a wind furnace, with a strong fire, for six or seven hours." We have a Magisterium Martis vitriolatum: B. Dissolve steel in rectified spirit of vitriol, then coagulate, so have you a magistery green like vitriol." And the therapeutic properties of this preparation are: "It opens oppilations of the liver and spleen, and cures the jaundice, quartans, melancholy, cachexia, and the green sickness. Dose, 3ss. in Rhenish wine." A tint suggestive of that of saffron would appear to have inspired the application of the distinctive term crocus to some mar-

dozen of them, with special supplements. One is thus accounted for: "Crocus Martis Quercetani, the opening crocus of Quercetan. R. Spirit of sulphur and spirit of wine ana, put them into an iron ladle, and boyl them at a soft fire, till they are evaporated; then lay the ladle by for 6 or 7 days, and brush off the yellow crocus. Or thus: Anoint plates of iron with oyl of sulphur, or sprinkle filings of steel therewith; and put them in a cellar for a week; then wash off the crocus with water (which will settle) and calcine it a little to make it red. This is called calcination by illinition. It is a great opener, a true restorer and comforter of the liver, and a certain cure for the green sickness. Dose, à gr. iij ad vij." \nd of oleum ferri album we are informed that: "It opens obstructions of the liver, spleen, meseraicks and womb, cures melancholy, the black jaundice and quartans, and is excellent in febri alba, sive morbo virgineo, the green sickness; dose, à gut. iiij ad xii in broth or Rhenish wine." preparation of "Magisterium Martis Salmonianum, the author's magistery of Mars," represents a version of the modern citrate, which is interesting in its primitive crudeness: "Dissolve filings of steel in purified juyce of lemmons, digest for a month, then filter into a glass vessel, and in a sand heat inspissate to the consistence of a liquid extract. The remainder of the chalvbs, which will not go through the paper, dry, and reduce into a subtil powder for the same use, or for steeled wine." A specially ingenious combination is found in the Tinctura Martis & Veneris of that encyclopædic pharmacologist: "B. The flegm or volatile spirit drawn from the vitrol of verdigresse by a retort in sand, and put in upon filings of iron in a narrow mouthed vessel, and in about half an hour (without any fire) the essence of Venus will be impregnated with the blood of Mars; abstract the menstruum or humidity, and from the fusible crocus with s. v. extract a tinc-

The lapse of nearly three quarters of a century, till the publication of the great Dictionary of the inventor of the "fever powder," gives an opportunity of estimating the progress—not always rectilinear, and sometimes even retrograde—of medicine and its ancillary sciences in the important period which witnessed the intellectual brilliancy of Locke and Newton at home, and the more closely related investigations and results of Stahl and of Boerhaave on the Continent. An interesting illustration of the raison d'être of the early saccharated preparations of iron is found in

Mars cum succhare brasparatus: A preparation of iron with sugar. Take filings of steele, three ounces; and brown sugar-candy, 'two ounces: let them be rubbed together in a dry mortar, to a fine powder. This will certainly require great labour before the steel will be fine; though the sugar will help to break it, and is of much the same effect with it, as the salt of tartar; but may make it more pleasant in some forms. It is said to be thus made in our Hospitals. And a mode of preparation of almost antedluvian simplicity is exhibited in that of "Crocus Martis Apricins. Opening Saffron of Iron. Let thin plates or filings of iron be exposed to the air in dewy nights, and rain, until they become very rusty; then clear off the rust, and do as before, until the whole is so changed: Let all be rubbed in a Mortar, and passed thro' a fine sieve. This is the most proper aperient preparation of all that are in use; because the acids, which are in most others made use of to dissolve the iron, render it rather astringent, especinally in the primes viæ; and what the college order under

this title, with sulphur, is rather astringent than aperient." We find sometimes that our author's opinion is diametrically opposite to that of Salmon; for instance, he confidently states that: For medicinal uses, iron is preferable to steel; and the filings of iron reduced to an alcohol, or impalpable powder, are preferred, by many, to all other preparations, in promoting the flux of the menses, and in removing obstructions of the viscera, being given from twelve grains to half a dram, once or twice in a day, in pills, lozenges, or boluses.

James's treatment of the subject of iron wine throw an instructive sidelight on the chemical physics, as well as on the physiological therapeutics His instructions for the preparaof that period. tion of iron dissolved in Rhenish wine are

Put two ounces of bright iron filings into a bolt head, and add thereto twenty ounces, of generous Rhenish wine; digest them together in a gentle heat, for three or four days, often shaking the glass: Let them afterwards which will appear black and keep it in a close stopped vessel; it is of a sweetish inky taste: Pour fresh wine on the remainder, and proceed as before. Thus, also, a chalybeate wine will be obtained, but no way comparable to the former; for the particular part hence obtainable is soon extracted from the iron by the wine; the whole body of the metal not being here dissolved; so that the production is not a solution, but a tincture.

And the author's appended "Remarks" proceed as follows:

Hence it appears that iron contains one part which is soluble, and another that is insoluble, in this mild, fermented, oily vegetable acid. The former part is the noblest remedy I am acquainted with, for promoting that power in the body by which the blood is made, as often as it happens to be weakened, through a bare debility of the over-relaxed solids, and an indolent, cold, aqueous indis-position of the juices. If an excellent medicinal virtue position of the juices. If an excellent medicinal virtue may, by any experiment, be gained from metals, certainly it is this; for no virtue of any vegetable or animal substance, no diet, nor regimen, can effect that in this case, which is effected by iron; but it proves pernicious where the vital powers are too strong, whether they proceed from the solids or fluids. I have often thought whether this was not the potable sulphur of the metal, that so powerfully resists the debility of nature; a medicine infinitely superior to the boasted aurum potabile, and a medicine that Hence we see, that iron has a part not very remote from a vegetable, and even an animal nature, and which is extremely easy to dissolve.

And in discussing "A Vitriol of Iron," James makes some clinical comment which may inspire the more accurate scientific thought of the reader of today:

We know that when iron filings are taken in female disorders, where the body is weak, languid, and abounds with acidity, the metal thus produces eructations, as of garlic and putrid eggs, on account of the acid it meets with; and nence the heat, before wanting in the body, is excited, and the excrements generally turn black, and in this case the powder of iron filings proves much more serviceable than when ever so laboriously prepared by chymistry. Whence iron is known to prove useful, if acids abound in the body, but hurtful where the body is

The painfully slow evolution of the pharmacopœial preparations of the present day is peculiarly well illustrated in the case of a remedy which has always attracted so much popular attention and secured so large a proportion of popular faith as did iron. Many of the best known names of the dawn and twilight of modern chemistry are associated with the special products of their iatrochemical invention in this department. The tinctura Martis Ludovici and the tinctura Martis Mynsichti obtained -with some inevitable Caledonian modificationshonored places in the Edinburgh Dispensatory of the early eighteenth century. The tinctura Martis Glauberi, "Glauber's tincture of steel," was placed in the London Dispensatory, with the following instructions for its preparation:

Take of Rhenish tartar, and filings of steel, of each four ounces; reduce them into a fine powder, and boil them in a sufficient quantity of spring water, in an iron pot, that two gallons may remain after six hours boiling; filtre that hot, and then evaporate it to five pints

Dr. James's comment was, however, decidedly unfavorable: "But what is intended to be done with it, cannot well be guessed; for it will neither keep. on several accounts; nor is it fit to take, because of its nauseousness."

There was also a bitter infusion due to the prescription of Lower-whose name is indelibly stamped on the history of anatomy in connection with the intercaval "tubercle" of the right auricle, and on that of physiological surgery from his pioneer practice of transfusion of blood. It was thus prepared:

Take of the tops of wormwood, and the lesser centaury, each three pugils; of the seeds of carduus benedictus, six drams; of gentian root, an ounce and an half; and of the filings of steel, six ounces; let them be macerated for fourteen days, in three pints of alexiterial milk water. mix'd with one pint of the lesser compound wormwoodwater, as prepared in the London Dispensatory; and a pint and an half of the lesser compound spirit of wormwood, as prepared in the resset compound spirit of wormwood, as prepared in the same dispensatory. Let the vessel be shaken three or four times a day, and the infusion only strained immediately before it is to be used. The dose of this infusion is four or six spoonfuls, to be taken each morning on an empty stomach.

There existed in those days, too, an astringent tincture of iron, which possessed a high reputation in the treatment of pulmonary consumption as the tinctura antiphthisica. The following is Geoffroy's prescription for the same;

Take of the vitriol of iron, an ounce; Terra foliata tartari, two drams; powder them separately; then mix them by degrees in a glass mortar, rubbing them constantly. by degrees in a glass mortar, rubbing them constantly, during the mixture, till they turn to a kind of soft paste of a red colour; then pour upon them, gently, four ounces of rectified spirit of wine, which will presently acquire a red colour, and is then to be poured off by inclination from the fæces. The dose is from ten to thirty or forty drops.

And that eminent pharmacologist subscribes the information that:

It stops hæmorrhages, gonorrhæas, and the fluor albus It stops hæmorrhages, gonorrheas, and the fluor allows in women. It cleanses and dries ulcers in the lungs, and is often prescribed with advantage in consumptions, mixed with equal parts of balsam of capivi. In the preparation, I have rejected the sugar of lead commonly used, and have substituted in its place the terra foliata tartari, which extracts the tincture full as well, and free from all the inconveniences which attend the inward use of preparations of lead.

The next—and approximately modern—era in the evolution of martial therapeutics was ushered in by the publication of the views of Friedrich Hoffmann (in 1753) regarding the intimate nature chlorosis, as it gave another new and powerful impulse to inquiry and speculation in this same department of clinical theory and practice. For the pathology and genesis of the chlorotic condition had remained a profound mystery to Sydenham himself. and to his inquiring successors of the next generation. And I am glad to have the opportunity of pointing out to the readers of this Journal that the very first successful essay towards a truly scientific and enlightening account of the treatment of the various anæmias by ferruginous waters was the

work of an Irish medical man (1757), the celebrated chemist, John Rutty. Since the date of his long unrivalled work on *Mineral Waters*, the subject of "ferruginous" therapeusis has never been lost sight of in Ireland; and one of the special hopes of the present writer is that the progress of our Irish Renaissance will soon be accompanied by a renovation of the well deserved reputation of the many Irish mineral springs which have been gradually allowed to sink into an unmerited oblivion since the date of the "Union." This pioneer of modern therapeusis wrote of ferruginous waters as tonics; and emphasized their powers of promoting the digestion, improving the appetite, and increasing the activity of the circulation; also of determining a healthy intestinal peristalsis, as well as checking the discharges of diarrheea and dysentery.

The next important landmark in the history of martial therapeutics was erected by Halle (1802), and is represented by the publication of his epoch making observations on the "miners' anæmia" Anzin, and the successful treatment of the same by the internal administration of preparations of iron salts. And, as chemistry was at that time entering on its stage of modern regenerative growth, the greater solubility—or, rather say, the greater resistance to precipitation-of the organic compounds of iron was utilized in the hope of more satisfactory absorption, and of avoiding an increase of intestinal irritability where such symptom existed. Of these the tartrate ferrico-potassique has always found most favor in the eyes of the countrymen of Lavoisier. Subsequent reference will be made to its "specific" powers, in the estimate of Ricord; it formed the essential ingredient in the boules de Nancy, which figured in the Codex of 1866; and in the boules de la Grande-Chartreuse-of baptismal connotation so engagingly prepossessing! Perhaps, after all, one of the most important of modern practical hints for the administration of iron is that of Soulier: "L'acide carbonique importe également; une eau ferrugineuse doit être gazeuse, sinon elle pèse sur l'estomac."

By one of those auspicious coincidences which we find to occur in the pages of scientific, as well as in those of political, history, Halle's announcement of the recognition and satisfactory treatment of that new clinical entity was one of the special medical events of the dawn of the most active and productive of all the scientific centuries. It was at that period that the illuminating rays of the newly risen aurora of chemistry had just commenced to radiate over the firmament of the hemisphere of intellectual enlightenment and progress. From that date the mysterious necromancy of the alchemist sank below the level of the horizon of experimental philosophy, and the (perhaps sometimes too) "positive" science of modern chemistry began its auspicious century of sovereignty. The chain of events which succeeded the somatic death of its immortal founder, Lavoisier, offers an encouraging example of the appropriateness of a parallel application of the heraldic aphorism of hereditary monarchy in matters political: "The king is dead; long live the king." The fiendish votaries of "liberty, equality, and fraternity," murdered the greatest experimental philosopher of his generation, did not pretend to seek for a better motive than that they "wanted no savants" in their new and glorious republic! (It is not, of course, impossible that even a century later, and a long way nearer home, might be discovered a populous "scientific" institution governed upon precisely similar principles—although not possessed of the legal privilege of the estoppel furnished by the application of the guillotine.) From the death of Lavoisier the scientific mustard seeds of his sowing grew and increased visibly, year by year-almost day by daytill the trees of the resulting forest of scientific growth came to cast their refreshing shadows over the surface of every civilized land. And the very familiar element of iron came in for a full share of the attention. Its enormously wide distribution throughout the tissues of the representative members of the animal and vegetable kingdoms had been little suspected before the days of the methods of minute analysis, on account of the smallness of quantity usually present. The existence of this element in the colored blood corpuscles was now satisfactorily demonstrated, and it was proved to be an invariable and essential constituent. Another forward step revealed the fact that the special compound within the corpuscle, to whose formation iron was absolutely essential, was that which gave it the characteristic color-and through that medium to the mass of the vital fluid, as recognizable by the naked eye. Not long after was announced the "discovery" that iron was the true oxygen bearer of the hæmoglobin molecule; and that oxyhæmoglobin corresponded to a ferric oxide, while the reduced hæmoglobin was analogous to a ferrous. In contact with the oxygen of the air, the latter instantly became oxidized into a ferric compound. In appropriate contact with the tissues of the various constituent parts of the organism, the ferric compound was, in turn, as rapidly reduced to ferrous. And thus was the red corpuscle constituted the receiver, the carrier, and the distributor of the "life giving spirit"—i. e., the respiratory oxygen of the physiological chemistry of the nineteenth century! Hayem advanced his contributory ray of scientific light with the assertion that the red corpuscles of the blood were invariably formed by the physiological appropriation of the requisite iron by the hæmatoblasts (of his own discovery). But he never succeeded in catching the iron in process of transit. Quincke was more fortunate—in the demonstration of his own leucocytic (hypothesis of the) origin of the red cell; he established its stages by injecting a ferrous solution, and demonstrated: (1) Formation of a ferric oxide: (2) precipitation of albumin by the samein form of fine granules; (3) the incorporation of the latter by the leucocytes—where they were demonstrable by the application of ammonium sulphide, or of potassium ferrocyanide and hydro-chloric acid. The basic physiological feature is the same, whatever be the line of development: the red corpuscle is the receiver, carrier, and distributor of oxygen; by virtue of the functional powers of its hæmoglobin-that is to say, of its iron.

As soon as the discovery of the presence of iron in the most essentially characteristic constituent of the vital fluid of the animal economy had been so

demonstrated, and its modus operandi in the duplex function of circulation and respiration had been firmly grasped, the absolute necessity of its presence for the maintenance of physical health and vigorand even of life-was, of course, fully recognized. And, accordingly, the immediate induction from the data so furnished was that, wherever there existed a deficiency in the quantity or quality of the cir-culating blood, the introduction of iron into the system was the alpha of the clinical treatment; and the same reacted almost (if not quite) to the omega. Then, in the inevitable sequence of events, it soon came to be noticed that even the unlimited administration of therapeutic iron was by no means always followed by the wished for result. Accordingly, in the interest of progressive scientific truth, the necessity for an explanation was recognized. It was reported that the assiduous employment of iron caused troublesome disarrangement of the digestive functions-which might interfere with its absorption, or unfavorably influence its subsequent assimi-This gastrointestinal malpraxis was said to be (at least partially) due to the fact that the martial salts produce a local astringent action-a contraction of the blood vessels of the mucous membrane, with consequent diminution (and deterioration) of the natural secretion. Their presence was also productive-by direct influence, physical or chemical, or a combination of both-of inhibition or arrest of the activity of the digestive ferments. Further investigation gave reported results which went to throw doubt on the reality of the assimilation of any medicinal iron, and even on its absorption from the surface of the gastrointestinal mucous membrane. It was experimentally demonstrated that the quantity eliminated from the digestive canal exactly represented that introduced by the mouth! The explanation which was manufactured to meet this really startling difficulty was that the undeniable clinical influence of ingested iron on the constitution of the blood was-in a quite indirect manner-attained by its stimulation of the gastrointesti-

the indirect production of chlorophyll.

Thus the tonic action of ferruginous preparations seemed in such light to be strictly comparable to that of vegetable "bitters." Mitscherlich advanced the hypothesis that iron salts were absorbed in albuminous combination; and others suggested that the iron atom, preparatory to absorption, definitely replaced a corresponding proportion of the hydrogen of the albumin molecule. Then came forward Bunge and Podwissotzki, who enunciated the view that iron was absorbed with the ordinary digested aliments, in a state of organic combination. Of course, every one who has had any experience of chemical testing

nal surface, as a result of which the alimentary iron was more effectively absorbed. The corresponding

clinical effects of arsenical preparations in such cases lent a good deal of plausibility to this view.

Further corroboration seemed to be afforded by the

power which iron displayed in restoring the failing

verdure of plants, in presence of the fact that

chlorophyll itself was not a ferruginous compound.

So that the influence of arsenic and of iron in the

restoration of hæmoglobin to anæmic patients might

be strictly comparable to that of the latter element in

for the presence of metals in solution has had an opportunity of appreciating the presence of "organic matters" in preventing the precipitation of small proportions of the salts of iron. The former of the two last mentioned therapeutists advanced the ingenious hypothesis, to account for the action of ferruginous preparations in chlorosis, that the beneficial effects were due to its prompt combination with the alkaline sulphides that always formed a continuous series in the products of the disorderly digestion which accompanied this condition, and thus prevented the excessive waste of organic nutriment by anticipating to some extent their really destructive formation. In consecutive rotation, we have Schultz enunciating the theoretical explanation that the various members of the metallic group which includes iron, manganese, nickel, cobalt, and chromium, are all direct stimulants of cellular activity; while they impress oxygen and some other nonmetallic elements with a greater mobility, and, accordingly, determine by their presence the formation of albuminates. And with the rapidly increasing velocity of chemical progress, the inevitable crop of physical and clinical "mare's nests" sprang up in its wake. Luton (Paris, 1882) advanced the thesis that in ferruginous preparations it was the activity of the electronegative element only that was utilized in the animal economy; iron perchloride had on chlorosis the effect of the hydrochloric acid which it represented. Some observers attributed the tonic action of iron to its influence on the muscular walls of the bloodvessels; and at least one ingenious "authority" (Rossbach) affirmed that the collateral hæmostatic powers of iron perchloride were brought into evidence by contraction of the vascular walls in the direction of the longitude of the artery.

It is hardly necessary to point out that the power of coagulating albumin (which is referred to the acid rather than to the metallic elements) of some iron salts generally receives the credit of the hæmostatic influence. Some would attribute at least a considerable proportion of the salutary influence of iron on the nutrition of the system to disinfectant and antiseptic properties. Many (indeed, almost all) ferruginous preparations given by the mouth are reduced to sulphideswhence the blackening of the gastroalimentary mucous membrane and its whole contents; and this means the decomposition of putrescent gases (sulphuretted hydrogen, ammonium sulphide, etc.) and the appropriation of their sulphur. Sulphate of iron is also credited with extensive oxidation which necessarily follows the separation of its large proportion of oxygen. Kuhlmann advanced the ingenious view that iron sulphate functions as a perpetual disinfectant, by alternately dropping its oxygen to become a sulphide, and again seizing the oxygen of unstable organic compounds so as to reform as sulphate. But a special antiseptic power has been attributed to even metallic iron, and to its least soluble salts. Frankland found that bacteria which waxed strong and multiplied in sulphurous acid, and in cyanides and other deadly poisonous solutions, rapidly perished in the presence of metal-

lic iron. (!!)

Still, however, hypotheses may come and hypotheses may go, there is no disputing the fact that the proportion of iron in the blood is usually increased after the administration of iron by the digestive tract. (To this general rule I would, before proceeding further, parenthetically indicate the very important exceptions formed by the unsatisfactory results so often noticed in the attempt to treat the anæmia of chlorosis while neglecting the coexisting constipation; and the horribly disastrous ones which are necessarily produced by attempting to improve by the employment of ortho-dox ferruginous "tonic" preparations, the hæmic condition of subjects of wasting disease who are suffering at the same time—as so many of them are sure to be-from gastrointestinal irritability, congestion, or ulceration. Rapid elimination might possibly be the true explanation of the appearance of the total weight of ingested iron in the alvine evacuations. The alimentary iron is known to be eliminated, for the most part, by the bile, and in form of a phosphate—an inorganic salt. Some observers have maintained that iron administered medicinally is, in large proportion, passed out by the kidneys. There are, of course, certain solid grounds for this statement; but, as will be gathered from the views already referred to, the opinion has by no means secured unanimous corroboration. Claude Bernard has, indeed, as far back as 1854. affirmed that no increase of the iron of the portal blood followed the introduction of any of its preparations into the alimentary canal. He followed up this affirmation with the suggestive queries: "La chlorose ne serait-elle due qu'à un vice de digestion? Le fer ne peut il pas, par l'excitation qu'il produit, rétablir les actes troublés de cette fonction?" Buchheim and his pupils confirmed the experimental results and the chlorotic hypothesis of the great French physiologist. Yet we afterwards find MM. Debierre and Linossier demonstrating the absorption of iron from the digestive tube; Sir Andrew Clark making chlorosis an autoinfection of intestinal origin-which accounted for the therapeutic value of purgatives; the indication of unhealthy atmospheric influence implied in the name of "urban malaria"; and of its inherited share in the universal domain of pathological paternity in the epithet of a microbiosis. But this wheel of clinical opinion continues to revolve; and it seems hardly safe to try to stop the rotatory movement-even if the experiment were without hopeless scientific difficulty.

The ingestion of iron in excess of physiological necessity, or adaptability, or both, leads, as is well known to all clinical observers, to the development of symptoms of progressive discomfort, culminating in those of "martial" poisoning. The collective group of phenomena, so produced and exhibited, has received the inclusive denomination of siderismus. This includes the symptoms of a distressing artificial plethora, which are, necessarily, very much aggravated by the constipation which coexists. There is violent arterial pulsation—most conspicuously felt in the carotids, accompanied by distressing palpitation, bursting headache, and all the other symptoms of active cerebral congestion—even febrile temperature, intense flushing of the face, in-

jected conjunctivæ, tinnitus aurium, etc. As indications of the resulting gastrointestinal irritation and congestion, there is great epigastric tenderness. with a feeling of depressing weight and dull pain; and the necessary coexistence of darkly furred tongue, impaired appetite or complete distaste for food, and irregular repetitions of troublesome tormina or colicky spasms. But in cases in which the gastrointestinal mucous membrane had previously been in a very irritable—congested or ulcerated—condition, the additional irritative stimulation produced by the ingestion of preparations of iron will be found to give rise to continuous diarrhea; and to aggravate this symptom when previously present. This inevitable consequence has far too often given rise to the very worst clinical results, in the hands of "practical" physicians, who, being on the blissful side of theoretical knowledge, only knew (in this connection) that the "regulation" treatment for anæmia was the natural remedy of iron-and pre-

scribed accordingly! And I gladly take the opportunity of emphasizing the fact that on this account the internal administration of iron should never be resorted to in cases in which any pronounced organic disease (or even marked irritability) of the gastrointestinal mucous membrane is known to exist. Thus, it should not be used in the treatment of the convalescence of enteric fever, or that of dysentery, till a considerable period has elapsed; and should then be administered only with extreme caution, if at all. For the same reason, it should never be employed in tabes mesenterica or in pulmonary phthisis, although I have good reason to know that it sometimes is. The fact that syrup of the iodide of iron was in the days of its juniority recommended by a prominent French physician (Dupasquier, of Lyons) as a specific cure in the treatment of the pulmonary tuberculosis of children greatly increased (and supported) the area of the reputed clinical usefulness of iron. It must, indeed, be admitted that this is one of the least irritating of all the preparations of the inorganic salts, as the presence of (organic) sugar inhibits precipitation as far as possible (to a small minimum, of course).

In this connection may be mentioned a device for. the administration of iron in cases where, on account of gastrointestinal irritability, or other reasons, it might be thought undesirable to give it by the ordinary method of ingestion. Fubini, in 1885. resorted to bronchopulmonic absorption. He added 20 grammes of defibrinated ox's blood to 80 grammes of an aqueous solution of sodium chloride (0.75 per cent.). One hundred grammes of such mixture, dried by evaporation and carefully pulverized, were administered each time; and the promoter of this method of inhalation reported that 'pareilles inhalations augmentaient le nombre des hématies et de l'hematosine." The more immediately "royal road" to contact with the red blood corpuscles, and contributory formation of hæmoglobin, offered by this pulmonary route is also suggested in the inspiration of the Gallic epithet of "tonique respiratoire." In presence of the obsti-nately contradictory statements regarding the absorption of iron, to which reference has been made

in the preceding paragraphs, it is interesting to note that Buchheim (and various others) affirmed the presence of iron in nearly all secretions and excretions; and that Bistrow found that its medicinal employment could be made to double the normal proportion in milk, and hence suggested the treatment of infantile anæmia by the administration of

iron to the nurse That iron displays something of a specific "affinity" for the intestinal mucous membrane would seem to be pointedly indicated by the results of some experiments reported by Smith and Orfila, who killed a series of dogs by depositing in the subcutaneous tissue of the thigh of each 7.5 grammes of powdered vitriol (ferrous sulphate). Post mortem examination demonstrated, in each case, the presence of the characteristic lesions of gastroenteritis, with patches of congestion of the convex aspect of the liver. Those results argue strongly against the adoption of the hypodermic administration of the solutions of iron salts in cases where the usual oral ingestion has been contraindicated by the presence of gastrointestinal derangement; although this modification of ferruginous therapeusis appears at first sight an ingenious device for the profitable evasion of a formidable obstacle in the course of a pressing clinical necessity; and, as such, was at one time strongly advocated by many "practical" physicians who prided themselves on the possession of a gift of special resourcefulness in battling with disease. They demonstrate the danger of the remote (as well as local) irritation which is prone to follow. The development of gastroenteritis and of paralysis of the higher nerve centres are complications which have been found to follow the rapid passage of large doses of iron into the circulation of animals. Luton, who used dialyzed iron in experiments on hypodermic absorption, recognized effects comparable to those of a diffusible stimulant, and characterized the symptom group as ivresse ferrique. And he had recourse to a physical (mis-) statement in his advocacy of this preparation—rather strongly suggestive of the inspiration of the most pronounced specimen of the traditional "Irish bull": "La manière de prèparier cette substance prouvait qu'elle serait susceptible de traverser les membranes animales"—the guileless clinical scientist being blissfully unaware of the fact that dialyzed iron is the portion of iron solution which has not dialyzed! The only effect which Nasse obtained on repeating Luton's experiment was a local one of violent in-Hypodermic injection of citrate of flammation. iron was found by Binz to produce a general malaise in animals, which, after thirty minutes, culminated in vomiting, and gradually subsided through a lassitude of some hours. Injection of some of the (noncoagulative) double-salts directly into the blood yessels produced intestinal phenomena suggestive of the action of arsenious acid or antimony. There was extreme congestion of the large intestine and of the pelvic organs generally. The oxygen of the blood was in normal proportion, while the carbonic anhydride was greatly increased—the reverse of what follows the use of medicinal dosage,

Another item of pathological mischief which appears to have been specially prone to supervene

upon the hypodermic use of solutions of iron is the development of the renal phenomenon which was described by Kobert as the "metallic kidney" condition which comes to manifest itself as a result of the effort of the renal organs to eliminate the excess of iron that has found its way into the circulating blood. Kobert found that, in such cases. the iron accumulated in the cells of the living epithelium of the tubuli contorti, and to such a degree as to cause a manifest obstruction in the lumen of each. Apart from such exceptional developments, such a condition as chronic siderismus can, however, hardly be said to exist, for the quantity of iron absorbed by the gastrointestinal mucous membrane is far too small to occupy the functional powers of the eliminatory organs for any considerable propor-

tion of the period of diurnal activity.

Under the name of siderosis, Quincke described an interesting entity of pathological genesis, which should, perhaps, receive recognition in this connection. It is a condition in which iron is deposited in certain tissues and organs of the body in such a way as to be demonstrable microchemically-not quite satisfactorily otherwise. The iron, which is so laid down in siderosis, was derived from that of the hæmoglobin of the colored blood corpuscles; when the destruction of the latter had been effected too rapidly to permit the complete elimination; which is, in the normal state, one of the routine functions of the liver. And, after the original description and baptism by Quincke, Peters (Kiel, 1881) made two varieties: (1) Siderosis of the spleen and bone marrow, which develops, to some extent, in the majority of aged persons, and in a good many of the younger ones who have been the victims of chronic disease; and (2) siderosis of the liver, spleen, and bone marrow, which is found to be associated with the fatal intestinal catarrh of infancy. (In discussion of these pathological curiosities, it is, of course, necessary for readers and hearers to bear in mind that the term "siderosis" has also been utilized to denote the condition of lung which is generated by the inhalation of particles of steel, and which is but too fatally familiar in all manufactories of cutting and pointed steel instruments. On account of this very efficient source of ambiguity, it is desirable that the former should be always referred to as "Quincke's sidero-

With the unprecedented expansion of the domain of chemicophysical research in the latter half of the past century, new chemical properties-with associated clinical and collateral applications-revealed themselves to the observation of the empirical explorer. It was determined that iron precipitated many other metals from their solutions by virtue of its physicochemical property of being (atom ranged against atom) more electropositive than they. The recognition of this physical relationship led Dumas and Edwards to propose the employment of iron, "reduced" by hydrogen, as an antidote in cases of poisoning by the salts of copper, of mercury, and of lead. Then Berthold and Bunsen proposed the treatment of cases of poisoning by arsenic ("arsenious acid") by administration of moist (freshly precipitated) ferric oxide (peroxyde

de fer gélatineux). With it, especially in presence of a little free ammonia, arsenious acid forms, in the intestinal serosity, an insoluble salt, which may

be afterwards eliminated in safety.

Special manifestations of contact action were noted and commented on. M. Burq would even explain the success of ferruginous therapeusis in chlorosis as a special item of his favorite metallothérapie. The local improvement of erysipelas attributed to various preparations were declared by some clinicians to be a manifestation of alterative properties, and by others-more "modern," indeed -to be due to antiseptic, microbicide powers. The employment of "dialyzed" iron, i. e. (lucus a non lucendo) of the iron which had not traversed the dialyzing membrane, was specially recommended by Da Costa and Luton for the purpose of hypodermic medication. The local caustic action of concentrated solutions is accounted for by the affinity of iron and albumin; the good effect of the perchloride salt-that most frequently used-in the local treatment of diphtheria has, by some, been credited to

antisepsis.

In the pursuit of the growth and development of our combined scientific and clinical knowledge, the only safe, and the only justifiable, attitude which can be adopted in summarizing our scientific and clinical knowledge of this very important element is to admit, freely and frankly, that our most reliable and clinical data in this connection are those which have been furnished by empirical observation -not by scientific experiment or physical demonstration. The undeniable results of all collective clinical research go, I believe, to prove that, while the preparations of this metal form a practically "specific" means of cure in the anæmia of chlorosis, they are not to be so fully relied on in the management of other varieties. The same mass of testimony goes to prove that in order to obtain the full benefit of its blood-making power, free action of the bowels must be maintained throughout; also, so far as I have personally been able to ascertain, that they are most reliably secured when the administration of iron is combined with that of arsenic. The many other actions, real and imaginary, which have at various times and seasons been attributed to the preparations of this metal, are, at least for the most part, well known, in a general way, to all well informed practitioners; while a considerable proportion of the views therewith associated are not, in the present state of our knowledge, of sufficient importance for special critical discussion. The bird's eye historical view furnishes, indeed, many curious items of anticipation of modern practice, conceived in the ages of prescientific obscurity. The use of baths of solutions of salts of iron—as tonic and specifically cutaneous reagents-in the classic Roman centuries, surely had their prophetic significance. And the emphatic aphorism of the celebrated syphilographer, Ricord, that the tartrate ferricopotassique was "the born enemy of phagedæna"—in the treatment of which he used this salt both locally and internally-pretty surely owed its genesis to some corresponding revelation of the light to come. The uses of therapeutic iron, which are unquestionably beneficial, and to which I have referred in the course of this communication, may, in many instances, be attributed to some similar inspiration. Some wise physician said—or surely should have said—that the most valuable advice which the physician gives to the average member of his clientele is that of Punch to young men under special trying circumstances of consultation: "Don't!" The patient and his friends are usually but far too ready to do a great deal too much. And if the writer of this article could but hope that its perusal would contribute to check, permanently, the prescription of "tonic" iron in the anæmia of the intestinal irritability of tubercular disease (to say nothing of the respective associations of fever, infancy, and senility), he would hug himself with the gratifying self-satisfaction due to the assurance that his professional life had not been lived in vain.

34 YORK STREET.

A CASE OF ADIPOSIS DOLOROSA WITH INVOLVEMENT OF THE LARGE NERVE TRUNKS.*

By P. N. Bergeron, M. D.,

Among the number of cases of adiposis dolorosa reported since the publication of the original papers of Dr. F. X. Dercum, very few have presented the interesting symptom group present in the case which it has been my good fortune to study.

CASE.—The history is that of a middle age woman, forty-five years of age, from the Out Patient Department of Jefferson Medical College Hospital. Through the courtesy of Dr. F. X. Dercum I have the privilege of presenting it

to the society for your discussion.

The family history is as follows: The father died at the age of sixty-four years, after a succession of apoplectic age of sixty-four years, after a succession of apoplectic strokes. He had been a constant user of alcohol, frequently indulging to excess. The mother died of pneumonia at the age of eighty-four years. She had been blind for thirty-two years. The cause of the blindness was probably chronic glaucoma. One brother died of pneumonia at the age of thirty-four years. He had been a diabetic for ten

years prior to his death.

The previous history of the patient is rather interesting. She had measles during childhood, and at the age of twenty-seven years suffered for three months from trau-matic spine. Three years later the patient began to suffer from a curious condition which recurred at frequent intervals until the present illness developed. During these attacks she suffered from numbness in the fingers which at times amounted to pain. A few minutes afterward the fingers became pale, cold, and felt as if they were being fingers became pale, cold, and telt as it they were being squeezed. This was again followed by a tingling and burning sensation. While the phenomenon lasted she was unable to feel or hold anything. At the age of thirty-five years she had a severe attack of influenza, with a protracted convalescence. The menstrual function began at the age of nineteen years. The periods were regular, somewhat painful, lasting six to seven days, the flow being copious. She was married at the age of thirty-two years. She was married at the age of thirty-two years. Although three times pregnant, gestation always terminated in miscarriage. Her husband had eight children by his former wife, two of them died in infancy, six are living and well. The menopause occurred at the age of thirty-seven years. Soon after the onset of menopause she began to grow stout, and in two or three years her weight had increased from 125 to 170 pounds.

The patient never used alcohol, nor could a history of syphilis be elicited. From the time she left school, at the age of nineteen years, until her presnt illness, she has always been actively employed; before her marriage as a worker in factory, and afterward with the care of house-

hold duties

The present illness began three years ago, with pain in the outer unface of the right arm and shoulder. In a

^{&#}x27;Read it a meeting of the Normalogue A Society of Philadelphia,

week or ten days the pain had extended to the forearm and hand. A week later the same phenomenon occurred in the left arm. Seven to twelve days subsequently it was also felt in the outer areas of the right thigh, which soon extended to the leg and foot. It was only a short time afterward that the same condition occurred in the left leg. The pain at times would be burning in character, while at other times it was dull and aching. Within two or three months of the onset the patient began to experience weakness in the knees and feet; she would stumble and frequently fall. Weakness in the arms and hands developed somewhat Weakness in the arms and hands developed somewhat later. Vomiting and diarrhoad were frequently present. Chilliness, numbness, tingling, and burning sensations in the extremities, as well as palpitation of the heart, fullness in the head, dizzines, and blurring of vision were often experienced. The skin was dry, the throat parched, and at times great thirst was complained of. Coincident with the vomiting she would have frequent and painful mictu-

She received treatment for general rheumatism, with slight or no abatement of the symptoms. Within the past year the patient began to have shooting pains in the hips, year the patient began to have shooting pains in the inps, along the spine, in the head, eyes, joints, especially in the small joints of the hands, and at different spots on the trunk. Her hand became very weak, and for a time her fingers were in a state of contraction. She became ex-

hausted easily, and her sleep was disturbed.

In her present state the patient complains of burning pain in the hands, arms, shoulders, feet, legs, hips, along the spine, in the occipital region, across the temples, in the the spine, in the occipital region, across the temples, in the eyes, the sides of the chest, and across the abdomen. These pains recur at frequent intervals, and at times are shooting in character. She is very nervous, irritable, emotional, and very forgetful. Often has sensation of numbness in the hands, arms, and legs, and at times has flashes of heat. buzzing sounds in the head, headache, dizziness, palpitation of the heart, and shortness of breath. Frequently there are attacks of epistaxis and vomiting. On few occasions blood has been vomited. Her flesh is very tender and bruises easily. Slight blows cause discoloration of the skin. She is easily fatigued, and during the past year her eye-

sight has been failing.

Examination.—The patient is five feet six inches tall and weighs 175 pounds. There are circumscribed accumulation of adipose tissue in the bursæ about the elbows, and at two of the metacarpophalangeal joints of elbows, and at two of the metacarpophalangeal joints of the right hand. The skin is dry, the subcutaneous adipose tissue is very sensitive, it lacks firmness and imparted to the palpating fingers the impression of masses of worms. There is no true Romberg sign. The gait is that of a weak person, and all reflexes are diminished. The grip of both hands is very weak, and there is marked weakness in all the muscles. There is, however no aparent may differ a trustee the state of the sta is marked weakness in all the muscles. There is, however, no apparent muscular atrophy. All large nerve trunks are very painful upon pressure. The heart is hypertrophied and the valvular sounds exaggerated. The pulse runs from 80 to 90 beats per minute, and there are slight atheromatous changes in the peripheral arteries. The liver is not enlarged and the spleen is not palpable. The uterus is senile and retroverted. Ovaries are not palpable. Examination of the eyes by Dr. LeFevre is as follows: Media clear; disc, obliquely oval; and the margin. Blurred. There is some absorption of the retinal pigment. Fundus otherwise healthy. She has a high compound myopia. Blood examination: Hæmoglobin, 80 per cent.; erythrocytes, 4,500,000; leucocytes, 8,000. The urine is negative except that the specific gravity is low, being 1.006. The treatment consisted of the administration of six grains of thyreoid extract and 25 grains of aspirin daily, as well as light massage. Although the treatment has only been instituted a short time I am able to report marked improvement. Recently the aspirin was discontinued and the thyreoid extract gradually increased, until she is now taking twelve grains daily.

taking twelve grains daily

Conclusion.—The points that I especially wish to bring to your attention are: First, the marked pain elicited upon pressure over the large nerve trunks; second, the sensitiveness of all of the subcutaneous adipose tissue; and, third, the presence of so few circumscribed masses of adipose tissue.

1832 GIRARD AVENUE.

Our Benders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

accided upon, the further questions are as follows:
L.X.X. How do you treat asphywia neonatorum.'
(Closed November 16, 1908.)
L.X.X.V.—Howe do you treat chronic eczema? (Answers due not later than December 15, 1908.)
LXXXII.—How do you treat chronic lead poisoning?
(Answers due not later than January 15, 1909.)

(Answers due not later than January 15, 1909.)
Il hover unswers one of these questions in the manner
most satisfactory to the editors and their advisers will
receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely
on the value of the substance of the answer. It is requested
(but not REQUINED) that the answers be short; if practicable, no one answer to contain more than six hundred

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.
All papers contributed become the property of the Journal.

OUR READERS ARE ASKED TO SUGGEST TOPICS FOR DISCUSSION. The prize of \$25 for the best essay submitted in answer to question LXXIX has been awarded to Dr. Samuel Sal-

inger, of Chicago, whose article appears below.

PRIZE OUESTION LXXIX.

TREATMENT OF SICK HEADACHE. BY SAMUEL SALINGER, M. D.,

Chicago.

The treatment of such an affection as migraine or sick headache is as varied as are the causes to which the disease may be attributed. In the absence of a specific actiology or pathology, we are compelled to closely interrogate the patient's history, both hereditary and personal, for available clues upon which to base our treatment, certain factors being generally recognized as having a direct or indirect bearing on the development and course of the affection. Among these are the inherited nervous temperament, a family history of migraine, epilepsy, hysteria, neurasthenia; the uric acid diathesis, digestive disorders, nervous strain, overwork, anæmia, various functional excesses, eye strain, and deficient activity of the thyreoid gland. As a rule, it will generally be found that two or three of these factors predominate in each particular case, and that consequently the success of the treatment will depend upon the accuracy with which the individual is studied.

As a matter of routine there are two procedures which should never be omitted; these are a careful examination of the eyes, and a thorough uranalysis. The eyes should be "refracted" under the influence of a mydriatic by a competent oculist, and the slightest error corrected. Furthermore, the extrinsic ocular muscles should be carefully tested, for it often happens that in the absence of a refractive error, merely the imbalance or weakness of one of these muscles has been found to be at the bottom of the trouble. and proper stimulation by the galvanic current has effected wonderful results. In all cases if the first examination is negative it should be repeated within a month or two.

A careful volumetric examination of the urine is

necessary to determine the standard of the patient's metabolism. Deficiency of the urea output, excess of uric acid, the presence of oxalates or indican, all demand special treatment. Exercise, fresh air, and attention to the digestion will assist the metabolism and insure a normal excretion of urea. Excess of uric acid can be combatted by restricting the diet in such articles as meats, rich foods, acids, and alcoholics, and by the use of the salicylates with the citrate or acetate of potassium. The presence of oxalates in the urine demands a carefully arranged diet, attention to the digestion, and the administration of the mineral acids, the nitrohydrochloric being preferable. When indican is present one's efforts should be directed toward promoting normal intestinal digestion and preventing putrefaction. Tonics and intestinal antiseptics are, therefore, in-

As mentioned before, it has been suggested that deficient activity of the thyreoid gland may have some influence over the course of this disease. Cases of migraine have been reported as being greatly ameliorated during gestation, a period at which we know the thyreoid to be functionally very active. Therefore where we have reason to suspect an overactivity of the gland, the thyreoid extract

should be given.

Patients of nervous tendencies must be cautioned against irregular habits. They should get sufficient sleep, plenty of fresh air, a moderate amount of exercise, and plain, wholesome diet. They must avoid worry and nervous influences, since these tend to maintain a state of depression and low vitality. It is well to encourage the patient by judicious talks, to exercise his own will in suppressing these nervous tendencies. This is especially essential in cases of excessive sexual or alcoholic indulgence. By healthful recreations and moderate exercise we can do much to occupy a mind that would otherwise gravitate to disturbing excesses.

The digestion is a point that demands careful consideration, since most writers are agreed as to its importance in bearing on this trouble. Digestive disturbances seem to account for a large majority of the attacks which a migrainous patient experiences. The diet should be as plain as is compatible with sufficient variety to avoid monotony—cold lunches, heavy meats, spicy or greasy foods, pastries and alcoholies must be interdicted. We may assist

further by giving tonics and digestants.

In addition to our efforts at removing the cause of the trouble and the general tonic, and reconstructive treatment, it is often necessary between attacks to resort to palliatives for the relief of the nervous irritability and fits of depression that so often obtain. These symptoms can generally be relieved by small doses of fincture of gelsemium and tincture of Indian cannabis, either separately or in combination.

As for the treatment of the attack itself it is possible to abort, or at least temper, the severity of the symptoms by prompt measures in the prodromal stage. The patient should be put to bed, the room darkened, and all noises excluded. The intestinal tract should be thoroughly emptied by the administration of a dose of salts. Locally, hot or cold compresses, according as the type is anæmic or con-

gestive, afford much relief, as also does the use of camphor or ammonia by inhalation. Occasionally the topical application of menthol to the supraorbital and infraorbital foramina and other neuralgic spots is a source of great comfort and may be advantageously employed. When there is much nausea food should be withheld and the stomach lavaged with warm water containing sodium bicarbonate and a few grains of menthol. In addition, a hot water bottle or mustard poultice applied over the epigastrium will afford relief.

Internally it generally is necessary to give an anodyne. Codeine and phenactine are best administered with a small dose of atropine or caffeine citrate to overcome their depressing influence on the citrate to overcome their depressing influence on the circulation. Aspirin occasionally affords relief, disadvantage of being irritating to the stomach. Where tolerated it should be given in 10 to 15 grain doses. For a day or more following the attack the diet should be mainly liquid. The patient should avoid reading or writing or sewing, should be carefully shielded from strong light, loud noises, and other disturbing influences, quiet pleasant surroundings and cheerful companions being more conducive to prompt recovery.

In conclusion, the points to be emphasized are

these:

1. The wisdom of avoiding opiates in view of the chronicity of the disease.

2. The importance of general tonic and recon-

structive treatment.

3. The necessity for individual rather than routine treatment and the proper elimination of all possible causative factors.

1023 EAST GARFIELD BOULEVARD.

Dr. Samuel Stalberg, of Philadelphia, observes:

1. The Attack.-Many patients can foretell the approach of the attack by experiencing such premonitory symptoms as general malaise, sense of pressure in the head, and dizziness, lasting for from a few hours to a day or two, followed by the appearance of spots before the eyes, scintillating scotoma, and hemianopsia, and more rarely, auditory disturbances, paræsthesia, and aphasia. sensory symptoms last for several minutes to half an hour, and in some patients are the only premonitory symptoms. But upon the first appearance of any of these prodromal symptoms, treatment should begin. The patient should be put to bed in a quiet, semidark room, and all sources of noise or confusion removed. A hot mustard foot bath should be given. A saline laxative, either an ounce of Rochelle salt, or a tablespoonful of magnesium sulphate, sould be administered. If the attack develops soon after a meal, grain 1/10 of apomorphine hydrochloride hypodermically or wine of ipecae and war n water should be given for emesis. The following should then be given:

This may partly abort the headache, but should be given every two or three hours during its continuance, if severe. The acetphenetidin in the prescription may be replaced by antipyrine; and less preferably acetanilide; indeed, as the effect of these analgesics often wears off, it is often necessary to use them alternately, at one time one drug, at other times another. In cases with severe headache, codeine, grain 1/8 to 1/4, may be added. Indian cannabis, grain 1/4 of the extract, of known strength, is a good palliative to add to the before mentioned mixture in some cases. In cases with a rheumatic history, sodium salicylate, grains xx, should be added to the mixture. Applications of cold water cloths or an ice bag should be made to the side of the head; although, as is often the case with hydrotherapy, hot applications sometimes afford greater relief. In the severer cases a hypodermic injection of morprine, grain 1/8 to 1/4, may be necessary. But in giving either the morphine or the coal tar products, due precaution should be taken against the patient becoming addicted to their use. He should never be permitted their use on his own account.

Strong tea or coffee is often beneficial during the attack. A mustard plaster over the nucha or over the course of the pneumogastric nerve in the neck, or menthol or chloroform liniment applied over the

same area, is often of benefit.

2. Prophylaxis.-Without stopping here to discuss the various theories regarding the nature of sick headache mechanism, suffice it to sav that we are justified, from the symptoms, in assuming the primary place of irritation to be in the brain itself; the gastric symptoms, nausea and vomiting, being manifestations of reflex nervous action rather than due to gastric disturbance. Now, what are the sources of irritation? The chief and most important is the eye-eye strain. In all cases of sick headache the eye should be subjected to a searching examination by a competent ophthalmologist. and any error of refraction or of muscular trouble, hyperopia, astigmatism, etc., corrected. And often when relief is not obtained at first, repeated examinations by the same or a different ophthalmologist will finally disclose the trouble. Such procedure will save in a good many cases the profuse dosing of the victim, or the sacrifice of time and money in sending him unnecessarily to some distant climate. In this connection it might be said that often in the attack due to this cause the instillation into the eve of an atropine solution will relieve the pain promptly. But in a great number of cases no eye trouble can be found, and glasses do not all relieve. Then we must look for other underlying conditions. are gout, lithæmia, rheumatism, digestive disturbance, anæmia, neurasthenia, and sometimes also dental caries, and diseases of the nasal chambers and their accessory cavities. All these conditions must be treated on the broad principles applicable to each one. Treat the patient, not the disease.

Constipation, with the resulting retention of waste products, should be treated by securing regular bowel evacuation; rheumatism and gout by salicylates and colchicum, and all three by proper diet, warm bathing, and plenty of out door exercise and fresh air. Nasal obstructions and adenoids, when clearly the cause of sick headache, should be removed. Anæmia should be treated with iron, etc. The teeth should be kept in good condition; and in a few cases correction of uterine disorders will

benefit.

Drugs for the sick headache itself are not of much use when given between attacks, but sodium bromide, grains xx, three times a day, or cannabis indica, grain ¼, or both together may be tried.

Finally, avoid exciting causes. For, whatever the underlying cause, or indeed, with no underlying cause, such exciting causes as fatigue, or more especially fatigue combined with excitement, worry, emotion, digestive indiscretion, etc., are sufficient to bring on an attack. Mental overwork should be guarded against.

· To be concluded. ·

Therapentical Hotes.

The Treatment of Lymphangeiitis. - When lymphangeiitis results from a wound on the finger. the best method of treatment, according to Stroll (Münchener medizinische Wochenschrift, November 10, 1908), is to bandage the finger with borated lint saturated with a fifteen per cent. solution of liquor alumini acetatis [the formula of the National Formulary is practically identical with the Liquor aluminii acetici of the German Pharmacopaia in diluted alcohol, and covering with gutta percha tissue. If the wound is situated near the tip of the finger, care should be observed not to turn up the gutta percha covering, so as to prevent the alcohol from evaporating. The dressing should be renewed three times daily. During these applications it is unnecessary to treat the glands. After the lymphangeiitis has subsided, boric acid ointment should be applied to the wound.

The Uses of Strychnine.-This forms the subject of an article in The Prescriber for November. 1908. The author recalls some of the applications of strychnine in diseased conditions. It is essentially a stimulant, and despite what is sometimes said to the contrary, a cardiac stimulant. To obtain this stimulating effect on the heart the administration of the drug must be continued for some time. It often fails to act on the heart at first, and for this reason the drug is often stopped just when its influence is at the point of asserting itself. Strychnine raises the blood pressure by increasing the activity of the vasomotor centre. This double effect of making the heart's action more powerful and of raising the blood pressure is of great value in many conditions of the circulatory system. It increases the activity of the respiratory centre in the medulla. a fact which should be borne in mind in cases of pneumonia. Hypodermic injections containing one sixtieth grain of the sulphate are valuable in such cases. The author remarks that many a patient with pneumonia who had been almost despaired of has recovered by this method of administering strvchnine. Under its action the respirations become deeper and the respiratory activity is greatly strength-Among the other indications in which the drug has proved useful is dyspnæa due to chronic chest affections, such as chronic bronchitis and pulmonary fibrosis. It is likewise a stimulating expectorant of considerable power, although this action of strychnine is seldom made use of. In fact, in pulmonary disease, it should be remembered that

strychnine not only stimulates the respiratory centre, but also stimulates the respiratory muscles, giving them more tone and greater power for action. In no condition are these two actions so well displayed as in emphysema, due to chronic bronchitis. Next to iodides, strychnine is, in such cases, our most useful remedy. Under its action the breathing soon becomes less labored, and the heart likewise is strengthened. As a general tonic there is no drug which can exactly replace it. By reason of its bitter property it increases the appetite. It also tones up the nervous and circulatory systems. It is, therefore, the ideal tonic for administration after all acute illnesses. Here it may be advantageously combined with a mineral acid and one of the bitter infusions, such as gentian. Cases of chronic constipation, especially when due to lack of muscle tone, derive benefit when treated with laxatives to which five or ten drops of the tincture of nux vomica have been added. The latter preparation, together with cascara, forms an extremely valuable combination.

The author recomends the administration of the

drug in the following forms:

| | \mathbf{R} | Solution of strychnine hydrochloride, B. P., m xlviii |
|---|--------------|---|
| | | Dilute hydrochloric acid, |
| | | Glycerin, |
| | | Compound infusion of gentian,ad 3vi |
| | M. | ft. Mist. |
| | Sig. | : One teaspoonful thrice daily in water after meals |
| | B | Tincture of nux vomica |
| | | Fluid extract of cascara, |
| | | Glycerin, |
| | | Peppermint water, |
| | M. | ft. Mist. |
| | Sig. | : One teaspoonful three times a day in water after |
| m | eals | |

Dried iron sulphate,gr. iiss; Extract of nux vomica,gr. 1/4. M. ft.pil. Mitte tales xxiv.

Sig.: One thrice daily after meals.

Abortive Treatment of Boils .- A combination of iodine and acetone is said (Formulaire de Pron) to be effective in aborting furuncles. The following solution is made:

After standing about fifteen hours the solution becomes black and syrupy, when it is ready to be applied.

It is best applied by means of a piece of absorbent cotton wound round the point of a wooden toothpick and saturated with the solution, this being passed lightly over the boil so as to blacken its sur-

face. Repeat in twenty-four hours if necessary.

The Pharmacy and Therapeutics of Paraldehyde.—In the course of an interesting, though lengthy disquisition on the therapeutics of paraldehyde, which is published in the Journal of the American Medical Association for November 14, 1908, it is observed that, while theoretically paraldehyde should be a stimulant and its action resemble that of alcohol, practically it is such a strong narcotic and hypnotic that its soporific and prostrating effects overcome any stimulant action that it possesses. It is noted that the first symptoms from paraldehyde are so intensely disagreeable and disturbing to the

patient that he or she will refuse to ever take the drug again. The dose of paraldehyde is from thirty minims to two fluid drachms. The following method of administering the drug is suggested in the article cited:

 Paraldehyde
 5ii;

 Olycerm
 5i;

 Water
 ad 5iv.
 M. et Sig.: A teaspoonful in plenty of water, at bedtime.

The National Formulary recognizes an elixir of paraldehyde, the dose of which is two fluid drachms, which represents thirty minims of paraldehyde.

The following formula, proposed by Thomas J. Keenan, in the Pharmaceutical Record for June 23, 1892, has been found serviceable for the exhibition of paraldehyde in a concentrated and easily assimilated form:

B Paraldehyde. Oil of cassia, M. xxx;
Pulverized sugar Si;
Water, ad 5xvi.
M. et. Sig: One to two teaspoonfuls or more as

In preparing this emulsion it is best to rub up the sugar with the yolk of egg and incorporate the paraldehyde and oil of cassia slowly and with constant stirring. The water should then be added in divided portions until the whole of it is taken up and a perfect emulsion formed.

The Untoward Action of Iodides Corrected by Arsenic.—Iodides, as is well known, set up in some patients all the symptoms of a cold in the head, even in small doses. Changes in the mouth, such as enlargement of the tongue, dribbling of saliva, etc., are occasional unpleasant symptoms. Difficulties in this way may frequently be overcome. according to D. M. Macdonald (The Hospital) by giving small doses of arsenic (Fowler's solution) simultaneously.

Local Application for Ozæna.—Tampons moistened with the following mixture should be applied to the mucous membrane of the nasal passages four times a week after the removal of crusts by means of tweezers. (Bulletin général thérapeutique, October 30, 1908):

| B | Iodine, Potassium | : | . 4 | . 1 | | | | | | | | | | | | | | | | g | Γ. | 2 | v | , |
|---|----------------------|---|-----|-----|---|--|---|--|--|--|--|--|--|--|---|--|--|--|--|---|----|---|----|---|
| | Menthol, | | | | | | | | | | | | | | | | | | | | | | | |
| M | Glycerin, | | | | ٠ | | ٠ | | | | | | | | ٠ | | | | | | | | 3х | |

Glycerin Suppositories.—A correspondent of the Pharmazeutische Zeitung for October 31st, communicates the following new formula for the preparation of glycerin suppositories:

| $\mathbb{P}_{\!\scriptscriptstyle E}$ | Cacao butter, | |
|---------------------------------------|----------------------------|-----|
| | Glycerin, | v; |
| | Anhydrous wool fat,gr. vii | SS. |

Melt together in a flask until a thick homogeneous liquid results capable of being poured into moulds of aluminum or tin about one and a half inches long and two fifths of an inch in circumference. Each suppository should weigh forty-five grains.

NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal and The Medical News.

A Weekly Review of Medicine.

Edited by FRANK P. FOSTER, M.D.

> Associate Editor. JOHN M. SWAN, M. D., Philadelphia.

Address all business communications to

A. R. ELLIOTT PUBLISHING COMPANY, Publishers,

66 West Broadway, New York.

Pulladelphia Office: 3713 Walnut Street.

CHICAGO OFFICE:

SUBSCRIPTION PRICE:

Under Domestic Postage Rates, 8;; under Foreign Postage Rate, 8;; single copies, fifteen cents.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail. Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, NOVEMBER 29, 1908.

THE INTERNATIONAL TUBERCULOSIS EXHIBITION.

The physicians of New York and its vicinity are to be congratulated on the coming of the Tuberculosis Exhibiton to this city. Held in connection with the International Congress on Tuberculosis, it probably brought together the most instructive and complete armamentarium against tuberculous disease ever seen. In Washington the exhibtion was daily visited by thousands, and there is no doubt at all that it was of enormous educational value. After all, the main weapon against the disease has been, and for some time to come will continue to be, education, but not the education of the masses merely. but also and especially the education of physicians.

While it suffices for the masses to grasp the broad principles of the crusade, it is the duty of all physicians to acquaint themselves with the details of the work. The family practitioner should be able to advise his patient concerning all the details of treatment, including the daily routine, the precautions to be taken to avoid infection of others, etc. He is also expected to know what facilities exist, both public and private, for the care of patients to be sent from their homes. His patient expects full information concerning situation, railroad fare, charges, class of patients received, where to make application, etc. Finally, the family physician must be able to direct the carrying out of modern phthisiotherapeutic measures in the home of the patient.

We venture to say that many physicians will be

surprised when the scope of the antituberculosis problem is brought home to them. This is all the more reason for every physician so to familiarize himself with the details of the work that he can take his place in properly directing it. We heartily commend this exhibition to the attention of our colleagues and can assure them that they will find in it much instructive material for study.

MEDICAL SOCIETIES AND LITERARY PROPERTY.

In the November number of the Pennsylvania Medical Journal there appears a paper with the following long title: The Ouestionable Ethics of Medical Journals in Publishing as Original Matter Papers Read at Medical Conventions: the Equal Rights and Privileges of All Medical Journals to the Publication of Papers Read at Medical Conventions; the Claims of the Medical Profession upon the Scientific Papers and Discussions of Medical Conventions. The title takes up thirteen of our contemporary's lines. The paper emanates from a well known Philadelphia surgeon, Dr. Oscar H. Allis, and was read in the general meeting of the Medical Society of the State of Pennsylvania in September. From several points of view it is remarkable.

It appears from Dr. Allis's account that last year he was announced to present a paper at the meeting of the American Surgical Association, whereupon the editors of Surgery, Gynæcology, and Obstetrics wrote to Dr. Allis requesting his paper for publication in that journal, and soon afterward he received a similar request from the editor of the American Journal of the Medical Sciences. He sent a copy to each of the two journals. Then he received a letter from the publishers of the American Journal of the Medical Sciences, Messrs. Lea Brothers & Co., in which they said:

Dr. Kelly has advised us concerning the article on congenital dislocation of the hip which you sent for publication in the American Journal of the Medical Sciences and also to another periodical, in contravention of the long standing rule of the Journal, printed in every issue. We have thus been put to expense for composition and illustrations which represents merely a loss to us, and, as it is only fair that you should reimburse us, we inclose a bill, at cost to us, for which we should be pleased to receive an

The bill amounted to \$38 (\$13.75 for composition and \$24.25 for engravings). The bill and the letter in which it was inclosed proved the starting point of a controversial correspondence between Dr. Allis and the firm, the whole of which-including a magistrate's command to "any constable of said city" (Philadelphia) to summon Dr. Allis to appear and "answer Lea & Febiger" (the new style of the firm

of Lea Brothers & Co.) "in a plea of debt or demand 'arising' from contract, either expressed or implied' "-is incorporated into Dr. Allis's paper, constituting more than half of the paper. The incipient litigation was at length dropped by the publishing firm, their bill remaining unpaid. Dr. Allis submitted to his State society the question of whether or not he was bound to pay the bill-that is, he wrote to his attorney: "I propose to refer it to the Medical Society of the State of Pennsylvania, and if that organization agree that I am in error both in law and honor. I will pay the bill that Lea & Febiger claim that I owe them, and send them an apology for my action." As this letter is included in his paper, Dr. Allis did virtually refer the question to the society, but we are not informed that a decision was rendered by that body.

Dr. Allis goes on to argue that no medical journal has a right to expect an author to furnish it with the text of a paper read before a medical society, asserting that such a paper is the property of the society. Of course he had not arrived at this belief prior to his furnishing copies of his paper to both Surgery, Gynacology, and Obstetrics and the American Journal of the Medical Sciences; otherwise he would have informed each of those journals that he could not furnish it with a copy of his paper. The fact that he has now reached such a conclusion can hardly be accepted, we think, as proving its truth as a general proposition. There are some societies which assert an exclusive right to publish the papers read at their meetings. If the proprietorship asserted by them is conceded by their members, nobody else can dispute it. We believe, however, that there are now but few societies which seek to exercise such an exclusive right, and we know that there are some which, having formerly sought to exercise it, do so no longer, for they have come to the sensible view that prior publication in a reputable journal does not detract from the value of their volumes of Transactions or of their other official vehicles of publication. But the great majority of our medical societies do not claim ownership of the papers contributed by their members; hence prevailing custom would seem to preclude the acceptance of Dr. Allis's contention as a general statement of fact.

Incidentally, Dr. Allis gave his audience an idea of his estimate of medical journalism in this country, saying: "There is scarcely a journal published in the United States that is not put forth by a publishing house, proprietary medicine vendor, food fakir, or supply shop, with the sole individual purpose of advertising its own wares. Back of the medical journal is the shrewd money getting business man, who never loses sight of the value of the buildingth that of a dollar and whose interest in the

ethics of medicine is akin to that the cannibal takes in the welfare of the missionary." He does not appear, however, to have discussed the ethics of sending the same article to two different journals without informing the one that it has also been sent to the other—a practice which is getting to be discreditably common.

THE NEW GYNÆCOLOGICAL HOSPITAL BUILDING OF THE UNIVERSITY OF VIENNA.

The Wiener klinische Wochenschrift for October 22d devotes much of its space to the opening of the new Gynæcological Hospital of the University of Vienna. Two papers read at the ceremonies and another independent paper, which are published by our Vienna contemporary, are of special interest—one by Professor F. Schauta, the second by Professor Alfons von Rosthorn, the successor to Chrobak, and the third by Dr. J. Fischer. From these three essays we gain a good view into the history of this world renowned institution.

As in the other European universities, obstetrics was treated at the University of Vienna only theoretically, by the teachers of medicine, up to the end of the eighteenth century. It was the old tradition that the physician was too proud to undertake surgery or obstetrics, and gynæcology has devloped only during the last fifty years, having previously been taught inadequately by the general surgeons. A practising physician was not necessarily also a surgeon or obstetrician; therefore the peculiar German title, Arst, Wundarst, und Geburtshelfer. Although a certain Rafaele Steidele read specially on obstetrics as early as in 1774, it was due to the initiative of Chancellor Van Swieten, called to Vienna from Leyden, that the first obstetrical department was opened in the new general hospital in 1784. This department received in 1834 a new building, still belonging to the general hospital group of buildings, and it is only since 1908 that the woman's hospital has had a home of its own. This building, according to the description given by Professor Schauta, and to judge by the illustrations and the plan which accompany the professor's paper, must be an imposing structure.

Of the men who have worked here, helping the sufferers, teaching the students, and assisting the practising physicians, we can only mention a few names: Simon von Zeller and Lukas Johann Boër (Boogers was his real name), the celebrated and much attacked obstetrician, were the first accoucturs, who were appointed, in 1786. In 1809 Heinrich Naver For became extraordinary professor of

obstetrics, to be followed in 1823 by Franz Güntner and in 1828 by Alexander Weiss and Elias Löbisch. In 1822 Johann Klein was placed in charge of the obstetrical clinic and became later professor of obstetrics, which position, to the detriment of the fame of the institution, he held until his death, in 1856.

In the mean time Eduard Mikschik opened the first gynæcological hospital, consisting of two rooms and being under the supervision of the general hospital, as a Klinik für Weiberkrankheiten. It was here that, in 1847, Semmelweis introduced the practice of irrigation with chlorine for the prevention of puerperal sepsis, after he had, independently of our own Oliver Wendell Holmes, demonstrated the causative factor of this dreadful fever, and to him the Germans and Austrians give the prize for this glorious discovery.

In 1858 Karl Braun von Fernwald (commonly called Karl Braun) succeeded Klein. Braun, Breisky, Späth, Chrobak, and Schauta became then the leading obstetricians of the Vienna school. While in 1784 only one obstetrical clinic existed, in 1834 this department was divided into two clinics, both attended by students and midwives. Five years later this arrangement was changed to a clinic for medical students and another for midwives. In 1873 a second clinic for students was opened. In 1774 the obstetrical clinic reported 285 births; in 1907 the three clinics reported over 12,000 births.

PROFESSOR GRAHAM LUSK'S HARVEY LECTURE.

It is a pleasure to record that one of the best Harvey lectures thus far delivered was that of our distinguished fellow townsman, Professor Graham Lusk, on Metabolism in Diabetes. The subject is certainly not an easy one to follow, but the speaker presented the salient facts so clearly that he held the close attention of his auditors throughout the lecture. According to Lusk, about eighty per cent. of the diagnoses of diabetes made by physicians at the present time are incorrect, the patients suffering merely from glycosuria. In true diabetes there is some serious disturbance of metabolism, so that sugar is formed even from proteid and perhaps also from fat. In glycosuria, on the other hand, there is merely an overtaxing of the capacity of certain organs to hold carbohydrate.

It was interesting to observe the vast amount of information which had been secured by means of animal experiments, and while it is true that we have not yet learned how to cure diabetes, we wonder whether any intelligent person would say we could forego knowledge gained in this way. After all, the rational way to find a cure for a disease is to study

the nature and cause of the pathological changes thoroughly. We have already learned that the glycosuria produced by injuries to the diabetic centre is not a true diabetes. When the operation is performed on fasting animals, i. e., on animals whose organs are free from stored carbohydrate, no sugar appears in the urine. We also know that the glycosuria produced by starvation is not a true diabetes. and the same is true of that produced by phlorizine. Animal experiments have also taught us the important rôle played by the pancreas in the metabolism of carbohydrates. This is usually believed to be an instance of an internal secretion. Animals suffering from a diabetes produced by complete extirpation of the pancreas can be cured by grafting a piece of pancreatic tissue beneath the skin.

The source of the urinary sugar in diabetes has long been the subject of controversy and investigation. Kossel pointed out that urinary sugar contained the same number of carbon atoms as the amino acids, and suggested that the amino acids of the protein molecule were the source of the sugar. In view of the researches of Fischer on the constitution of the protein molecule, such a formation is not difficult to understand. On the other hand, it is not easy to understand how alanine, which is optically inactive, is changed into dextrose, and yet, on feeding a diabetic dog with alanine, Lusk has seen an increase in the urinary sugar. Similar results have been obtained with a number of other amino acids, such as glycocoll, serin, and aspartic acid.

A point of considerable practical value is the amount of food required in diabetes. Normally about twenty-three per cent. of the heat value of protein is not used by the body, i. e., about seventy-seven per cent. of the heat value is really available. In diabetes, on the other hand, only about nineteen per cent. of the ordinarily calculated caloric value of protein is actually obtained by the organism. According to Falta, the diabetic actually uses considerably more calories than a normal individual, but this does not appear to be true, as the experiments on which Falta bases his view are open to serious objection. According to the figures obtained by Voit forty years ago, the diabetic uses about the same number of calories as the normal individual.

The diabetic's hope, of course, lies in the selection of a proper diet, and in order that he may have this it is important to determine the carbohydrate tolerance. Mandel and Lusk have recommended that the patient be placed on a fat and proteid diet, and that studies then be made of the diet to nitrogen ratio, i. e., the ratio between the carbohydrate and the total nitrogen in the urine. They believe that if this ratio is high, the prognosis is poor, while, conversely, a low ratio indicates a favorable prognosis. In con-

nection with the selection of a proper diet, it is interesting to note that in his experiments on diabetic animals, Allard, working in Minkowski's clinic, found that the ratio could be increased by feeding them with fat, and that this also increased the acidosis. The acidosis, as is well known, is directly asso-

ciated with diabetic coma.

In closing, Lusk said that, while it was easy enough to express the results of the activities of millions of cells in terms of calories, we were vet far from having an insight into the complicated processes going on within the organism. This, of course, is true. At the same time it was impossible to listen to the speaker's interesting recital without feeling that sooner or later these ingenious methods logically continued would bring the desired result, namely, a cure or preventive of the disease.

Hews Stems.

A Bust of Pasteur at Harvard .- A replica of the by Harvard University, and will be erected in the Medical School

In Memory of Laveran.—A medallion, commemorating the discovery of the parasite of malaria by Laveran, in 1880, has been placed in the Military Hospital of Constantine,

Algiers.
The Clinical Society of the Elizabeth, N. J., General Hospital held a meeting on Tuesday. November 17th. The paper of the evening was read by Dr. S. T. Quinn on Surgical Diseases of the Gall Bladder.

Dean of the Medical Faculty, University of Toronto.

Dr. C. K. Clark, of the Toronto Asylum, has been appointed dean of the medical faculty of the University of Toronto, to succeed Dr. R. A. Reeve, who resigned

The Harvey Society Lectures.—The fourth lecture of the Harvey Society will be delivered on Saturday, November 28th, at 8:30 p. m., at the New York Academy of Medicine, by Dr. Wilhelm Falta, of the University of Vienna.

The subject will be the Therapeutics of Diabetes.

Personal.—Dr. Daniel T. Millspaugh, of New York, met with a serious accident while driving with one of his patients recently. A dead tree fell directly across the carriage, breaking both of Dr. Millspaugh's legs above the

Rochester, N. Y., Academy of Medicine.—A meeting of this academy was held on Wednesday evening, November 25th. The programme, which was arranged by Section IV, included a paper by Dr. Park Lewis, of Buffalo, on the Prevention of Ophthalmia Neonatorum. The paper was illustrated by lantern slides.

An Annex for the Metropolitan Hospital .- Plans have been filed with the Building Department for the erection of a stone building 291 feet long and four stories high on Blackwell's Island, as an annex to the Metropolitan Hospital. The new building, which will be devoted to the care of tuberculosis patients, will cost \$250,000.

of tuberculosis patients, will cost \$250,000.

A Course of Special Lectures at the University of Wisconsin.—Dr. M. P. Ravenel, professor of bacteriology in the Medical Department of the University of Wisconsin, is arranging a series of lectures on hygiene. Professor William T. Sedgwick, of the Massachusetts Institute of Technology, is among the speakers.

The Sixth District Medical Association of Georgia with in August in Managara. No

met in annual session in Macon, Ga., on Wednesday, No vember 11th. Officers were elected as follows: President, Dr. A. F. White, of Flovilla; vice-president, Dr. J. W. Cowart, of Walden; secretary and treasurer, Dr. Eugene B. Elder, of Macon. The association will hold its next convention in Indian Springs, on the second Wednesday in

The New York Pathological Society and the New York Surgical Society will hold a joint meeting on December 9th. A paper entitled An Experimental Study of the Pathology and Metabolism in Delayed Chloroform Poisoning will be presented by Dr. John Howland and Dr. A. N. Richards. The subject will be discussed from a A. N. Richards. clinical standpoint

NEWS ITEMS.

American Urological Association.—The New York Society branch of this organization held a stated meeting at the New York Academy of Medicine on Wednesday evening, November 25th. The paper of the evening was read by Dr. Lewis Gregory Cole on Radiographic Diagnosis of Calculus in Cases having Obscure Histories. The paper was illustrated with lantern slide pictures.

Increase in Alcoholism Among Applicants for Enlist-

Increase in Alcoholism Among Applicants for Enlistment.—The annual report of the Surgeon General of the United States Army discloses the fact that the proportion of applicants rejected on account of alcoholism rose from 9.65 per thousand in 1905-06 to 75 per thousand in 1906-07. There seems to be no assignable reason for this increase. No change has been made in the regulations regarding alcoholism

Har-Moriah Hospital.—The Har-Moriah Hospital, on First Avenue, New York, was opened on November 15th by the President of the Board of Aldermen. The funds for the erection of the hospital were raised by private subscription. The name originally was Mount Moriah, but the Hebrew word har, meaning mount, has been substituted for its English equivalent, so as to avoid confusion with Mount Sinai Hospital.

Contagious Diseases in Chicago.—There were 791 cases of contagious diseases reported to the Department of Health during the week ending November 14, 1908, an increase of 184 over the preceding week. Of the total numcrease of 184 over the preceding week. Of the total number of cases, 237 were of diphtheria, 196 of scarlet fever, 142 of tuberculosis, 63 of typhoid fever, 56 of measles, 34 of chickenpox, 24 of pneumonia, 16 of whooping cough, and 23 of diseases of minor importance.

Changes of Address.—Dr. E. Franklin Smith, to 4 West Ninety-second Street, New York.
Dr. St. C. Royle, to 2131 Broadway, New York.
Dr. Julien A. Gehrung, to 11 East Forty-eighth Street.

Dr. Geor New York George T. Jackson, to II East Forty-eighth Street.

Dr. Reed B. Granger, to 1215 Vyse Avenue, New York. A Gift to Beth Israel Hospital, New York.—At the graduating exercises of the training school for nurses operated in connection with this hospital, held on Monday evening, November 23d, Mr. Adolph Lewisohn announced a gift to the hospital of \$10,000. Mr. Lewisohn's gift makes possible the beginning of the work on the new building for the hospital as soon as a suitable site has been secured. The facilities of the present building have long been wholly

Christmas Stamps on Sale.—The American Red Cross Society is placing on sale, through its various local branches, stamps conveying Christmas greetings, which are sold at one cent each, the proceeds from the sale to be devoted to the antituberculosis campaign. Many of the larger firms in Philadelphia and other cities have taken large quantities of the stamps, one firm having already ordered as many as 50,000. Details regarding the plan, which originated in Denmark some few years ago, are given in a communica-tion by Dr. S. A. Knopf, of New York, printed in this

The Aid Association of the Philadelphia County Medical Society held its annual meeting on Monday afterical Society held its annual meeting on Monday aftermon. November oth Dr George Woodward, the former
president, having declined reelection, officers were elected
as follows: President, Dr. James B. Walker; vice-president,
Dr. Jacob R. Shellenberger; secretary, Dr. Lewis H. Adler,
Jr.; treasurer, Dr. John B. Turner; directors for three
years, Dr. John B. Roberts, Dr. De Forest Willard, and
Dr. William T. Hamilton.

The New Bellevue.—Two new buildings for Bellevue
Hospital were formally opened recently at Twenty-sixth
Street and East River. These two buildings were begun
in 1905 and are included in the general plan for the reconstruction of Bellevue Hospital as a whole, the completion

struction of Bellevue Hospital as a whole, the completion of which plan will take something like five years more. The two buildings opened have about 397 beds and will contain two wards for children and two medical wards, the remainder of the building being devoted to maternity wards. The Medical Society of Virginia.—At the annual meeting of this society, which was held recently in Richmond, the following officers were elected: President, Dr. Stuart McGuire, of Richmond; first vice-president, Dr. I. C. Wright, of Jarretts; second vice-president, Dr. E. T. Brady, of Abingdon; third vice-president, Dr. E. T. Brady, of Abingdon; third vice-president, Dr. Reid White, of Lexington; secretary, Dr. L. B. Richards, of Richmond; and treasurer, Dr. R. M. Slaughter, of Richmond; Parallel Secretary and Parallel Sec mond. Roanoke was chosen as the next place of meeting.

Philadelphia County Medical Society.—The Central Branch of this society held a meeting on Wednesday, November 25th. The programme consisted of a "symposium" on vaccination. Dr. Alexander C. Abbott read a paper on on vaccination. Dr. Alexander C. Addott read a paper on the Role of the Bureau of Health in Public Vaccination. Dr. Jay F. Schamberg read a paper on Smallpox before and since the Discovery of Vaccination. Dr. William M. Welch read a paper dealing with the so-called dangers of vaccination. Hampton L. Carson, Esq., presented the legal aspects of vaccination.

New Building for the Naperville, Ill., Sanatorium .-Mrs. Keith Spalding has given \$18,000 to the Chicago Tuberculosis Institute for the erection of a new building for the Edward Sanatorium at Naperville, Ill. This sanatorium, built and equipped by Mrs. Spalding, was opened on January 15, 1907, its object being to afford proper care and treatment for tuberculous patients in moderate circumstances. The new fund provides for the immediate erection of a well equipped medical building, with all facilities for clinical and laboratory study, and accommodations for at least twenty additional patients in the curable stage of the disease.

The Superintendency of the Boston City Hospital.-The Superintendency of the Boston City Hospital.—
Dr. George H. M. Rowe, who has been superintendent of the Boston City Hospital for nearly thirty years, has been obliged to resign his position on account of ill health.
Dr. Rowe's resignation will take effect at the close of the fiscal year. The trustees of the hospital have appointed Dr. John H. McCollum, professor of contagious diseases at Harvard Medical School, as Dr. Rowe's successor. Dr. McCollum has been resident hysician of the South de-McCollum has been resident physician of the South de-partment of the hospital for the last thirteen years, and was city physician of Boston for fifteen years.

Infectious Disease in New York: We are indebted to the Bureau of Records of the De-partment of Health for the following statistics of new cases and deaths reported for the two weeks ending No-

vember 21, 1008;

Deaths. Cases. Tuberculosis pulmonalis 479
Diphtheria 337
Measles 180
Scarlet fever 215 173 23 499 361 172 Varicella Typhoid fever Typhoid fever
Whooping cough
Cerebrospinal meningitis 38

The Buffalo Academy of Medicine.-A special stated meeting of the Section in Obstetrics and Gynæcology was held on Tuesday evening, November 24th. The principal feature of the programme was a paper entitled The Choice of Operation for Uterine and Bladder Displacement and Prolapse, which was read by Dr. Isaac Stone, professor of gynæcology in the Georgetown University, Washington, D. C. The discussion was opened by Dr. C. C. Frederick, of Philadelphia. The Buffalo Academy of Medicine was in-corporated on November 10, 1908, and this meeting was called to adopt the constitution and by-laws.

The Mortality of Chicago.—During the week ending November 14, 1908, there were reported to the Department of Health of the City of Chicago 565 deaths from all causes, as compared with 539 for the preceding week and 528 for the corresponding week in 1907. The annual death rate in 1,000 of population was 12.60. The principal causes of death were: Apoplexy, 7 deaths; Bright's disease, 50 deaths; bronchitis, 14 deaths; consumption, 71 deaths; cancer, 27 deaths; diphtheria, 18 deaths; heart disease, 50 deaths; influenza 1. death; intestigal diseases, causers, 28 deaths; influenza, I death; intestinal diseases, acute, 48 deaths; measles, 2 deaths; nervous diseases, 15 deaths; pneumonia, 62 deaths; scarlet fever, II deaths; suicide, 7 deaths; typhoid fever, 7 deaths; violence, other than suicide, 38 deaths; whooping cough, I death; all other causes,

The Health of Pittsburgh .- During the week ending November 14, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 14 cases, o deaths; typhoid fever, 19 cases, 1 death; pox, 14 cases, o deaths, typhold fevel, 19 cases, I death; scarlet fever, 26 cases, 2 deaths; diphtheria, 25 cases, I death; measles, 23 cases, 0 deaths; whooping cough, 9 cases 0 deaths; pulmonary tuberculosis, 22 cases, 10 deaths. The total deaths for the week numbered 142 in an estimated population of 565,000, corresponding to an annual death rate of 13.06 in 1,000 population.

New York Academy of Medicine.- A stated meeting of the academy will be held on Thursday evening, December 3d, under the auspices of the Section in Ophthalmology. The subect selected for discussion is the diseases of the eye and orbit depending on diseases of the accessory nasal sinuses. Dr. George S. Dixon will present a paper, illustrated with lantern slides, on the anatomical relations. Dr. Arnold Knapp will read a paper dealing with the subect from the ophthalmological standpoint, and the rhinological standpoint will be discussed in a paper by Dr. C. G Coakley. Among those who will participate in the general discussion are Dr. C. R. Holmes, of Cincinnati, Dr. William Campbell Posey, of Philadelphia, Dr. Emil Gruening, and Dr. C. S. Bull.

New Location for the Philadelphia Clinic for the Home Treatment of Chest and Throat Diseases.—The

ociety

board of trustees of this institution recently purchased the property at 2114 Lombard Street, Philadelphia, and made application to the State Board of Charities for an appropriation to be devoted to remodelling the building to adapt it to the work of the clinic. Until these alterations are completed the clinic will continue to be held on Mondays, Wednesdays, and Fridays, at 3 p. m., in the rooms at 519 South Fifteenth Street, temporarily engaged for the purpose. The work of the clinic has been very satisfactory. Dr. Frank Read is president of the board of trustees, and Dr. Thomas J. Mays is the medical director of the clinic.

Major Mearns to Accompany President Roosevelt to Africa.—Much interest has been felt in the fact that Major Edgar A. Mearns, of the medical corps of the United States Army, who is to accompany President Roose-United States Army, who is to accompany President Roose-velt on his hunting trip to Africa, has been declared physi-cally unfit for promotion by an examining board before which he appeared recently. Under the recently enacted law reorganizing the medical department, Major Mearns will retire on January 1, 1909, with the rank of lieutenant colonel, since he has been declared physically unfit for promotion. Some surprise has been expressed that a man declared physically unfit for promotion should still be physically fit for a hunting trip to Africa with so strenuous a leader as President Roosevelt.

Scientific Society Meetings in Philadelphia for the Week Ending December 5, 1908:

Monday, November 10th .- Section in Medical History, College of Physicians.

TUESDAY, December 1st.—Academy of Natural Sciences; Philadelphia Medical Examiners' Association.

Wednesday, December 2d.—College of Physicians.
THURSDAY, December 3d.—Obstetrical Society; Germantown Branch, Philadelphia County Medical Society;
Southeastern Medical Society; Section Meetings,

Franklin Institute. FRIDAY, December 4th.—American Philosophical Society; Kensington Branch, Philadelphia County Medical

Officers of the Medical Society of the County of New York.—At the one hundred and third annual meeting of the Medical Society of the County of New York, held on the evening of Monday, November 23d, the following officers were elected: President, Dr. H. Seymour Houghton; first vice-president, Dr. John E. Weeks; scond vice-president, Dr. John E. Weeks; scond vice-president, Dr. Joseph Brettaur; secretary, Dr. John Van Doren Young, reelected; assistant secretary, Dr. J. Milton Mabbott, reelected; treasurer, Dr. Charles H. Richardson, reelected; censors, to serve two years, Dr. J. Riddle Goffe, Dr. Harry M. Painter, and Dr. Charles G. Kerley; delegates to the Medical Society of the State of New York, to serve two years, Dr. H. Seymour Houghton, Dr. Floyd M. Crandall, Dr. Ward Bryant Hoag, Dr. E. Eliot Harris, Dr. Henry M. Silver, Dr. J. Milton Mabbott, Dr. Abraham Jacobi, Dr. Michael C. O'Brien, Dr. Egbert Le Fevre, Dr. Frederic R. Sturgis, Dr. Arnold K. Knapp, Dr. Frank S. Fielder, Dr. Charles H. Richardson, Dr. John A. Bodine, Dr. Edward M. Foote, Dr. Edmund Prince Fowler, and Dr. Walter Lester Carr. Officers of the Medical Society of the County of New

Promotions in the Medical Corps of the Army.—A recent number of the Army and Navy Journal points out that during the next few weeks many promotions will take place in the medical corps of the United States Army. Colonel Philip F. Harvey will retire on December 12th, which will cause the promotion of Lieutenant Colonel Daniel M. Appel to the rank of colonel, Major John L. Phillips to the rank of internat of lieutenant colonel, and Captain Elmer A. Dean to the rank of major. The reorganization under the recently enacted law, which will take effect on January 1, 1900, will advance Lieutenant Colonels Harry O. Perley and W. B. Davis to the rank of colonel; Majors Guy. L. Edie, W. D. Crosby, C. M. Gandy, W. D. McCaw, Jefferson R. Kean, and H. I. Raymond will become lieutenant colonels; and Captains F. M. C. Usher, W. F. Truby, F. F. Russell, E. P. Wolfe, H. S. Greenleaf, L. T. Hess, C. C. Collins, B. J. Edgar, Jr., S. M. Waterhouse, E. H. Hartnett, C. S. Ford, C. E. Marrow, W. D. Webb, M. A. W. Shockley, R. N. Winn, T. C. Lyster, S. H. Wadhams, C. P. Robbins, and T. L. Rhoads will become majors. On January 14th Surgeon General O'Reilly will retire. Lieutenant Colonel W. W. Gray will become a colonel, Major H. T. Harris will become a major. Society Meetings for the Coming Week:

TUESDAY, December 1st.—The New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Buffalo Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City); Medical Association of Troy and Vicinity, N. Y., Hornellsville, N. Y., Medical and Surgical Association; Long Island, N. Y., Medical Association; Island, N. Wednesday, December 2d.—Society of Alumni of Bellevue Hospital: Harlem Medical Association, New York; Elmira, N. Y., Academy of Medicine.

Thursday, December 3d.—New York Academy of Medicine; Dansville, N. Y., Medical Association.

FRIDAY, December 4th.—New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynæcological Society, Brooklyn, N. Y.; Manhattan Clinical Society, Brooklyn, N. Y.; Manhattan Clinical Society, New York; Practitioners' Society of New York.

The Health of Philadelphia .- During the week ending November 7, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadiseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 31 cases, 3 deaths; scarlet fever, 49 cases, 4 deaths; chickenpox, 43 cases, 0 deaths; dipththeria, 72 cases, 16 deaths; cerebrospinal meningitis, 2 cases, 0 deaths; measles, 35 cases, 0 deaths; wbooming cough, 13 cases, 2 deaths; tuberculosis of the lungs, 125 cases, 51 deaths; pneumonia, 49 cases, 25 deaths; ervispelas, 6 cases, 1 death; puerperal fever, 4 cases, 1 death; mumps, 4 cases; cancer, 18 cases, 24 deaths; tetanus, 2 cases, 1 death; trachoma, 1 case, 0 deaths. The following deaths were reported from other transmissible diseases; Tuberculosis, other than tuberculosis of the lungs, 8 deaths; Tuberculosis, other than tuberculosis of the lungs, 8 deaths; Tuberculosis, other than tuberculosis of the lungs, 8 deaths; cholera morbus, 1 death; diarrhoea and entertitis, under two years of age, 25 deaths. The total deaths numbered 421 in an estimated population of 1,532,738, corresponding to an annual death rate of 14,21 in 1,000 population. The total infant mortality was 98; under one year of age, 80; between one and two years of age, 18. There were 27 still births; 12 males and 15 females.

During the week ending November 14, 1008, asset of

During the week ending November 14, 1908, cases of transmissible diseases were reported as follows: Typhoid fever, 30 cases, 10 deaths; scarlet fever, 72 cases, 8 deaths; chickenpox, 36 cases, 0 deaths; diphtheria, 113 cases, 14 deaths; measles, 36 cases, 2 deaths; whooping cough, 6 cases, 0 deaths; tuberculosis of the lungs, 165 cases, 65 deaths; presumeric cases, 4 deaths; accurately cases, 65 deaths; presumeric cases, 65 deaths; pneumonia, 65 cases, 34 deaths; erysipelas, 3 cases, 1 death; puerperal fever, 2 cases, 0 deaths; mumps, 10 cases, 0 deaths; trachoma, 2 cases, 0 deaths; cases, o deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 7 deaths; diarrhea and entertitis, under two years of age, 17 deaths. The total deaths numbered 484 in an estimated population of 1,532/38, correlated to 1 Bith of Current Titerature.

Acute Gonorrheeal Epididymitis, with Special Reference to the Operative Treatment,

to the Operative Treatment,

By John H. Cunningham, Jr.

The Law and Medical Experts, with Particular Reference to the Codes of Criminal Procedure of European Countries,

By Charles Greene Cumston.

Bursitis Subacromialis, or Periarthritis of the Shoulder Joint (Subdeltoid Bursitis) (To be continued),

By Ernest Amory Codman.

1. Acute Gonorrhœal Epididymitis.-Cunningham says that, in his mind, the operation advised by Hagner greatly lessens the suffering and diminishes the duration of the disease. Whether or not the epididymitis is left in a better condition to serve as a conduit for the testicular secretion cannot be determined. Hagner's technique is as follows The junction of the epididymis and testicle is defined and an incision two inches long is made through the scrotal skin in this line. The tunica vaginalis is opened when any fluid present escapes. The swollen epididymis with the testicle is delivered. The epididymis is punctured in many places with a sharp pointed knife. The punctures must penetrate the infiltrated fibrous covering and the body of the organ must be entered. If pus escapes the opening should be enlarged with the knife, and a probe should be inserted to enlarge the canal. Such cavities should be washed out with a fine pointed svringe filled with corrosive sublimate solution, I to 1,000, followed by salt solution. The epididymis should be gently squeezed to force to the surface as much of the infectious material as possible. This is sponged away with a sponge wet with the same antiseptic. The tunica vaginalis is washed thoroughly with corrosive sublimate solution, I to I,000, followed by a liberal amount of salt solution. A cigarette drain is placed over the punctured epididymis and brought out of the low-est part of the wound. The tunica vaginalis is closed by a continuous catgut suture and the scrotal skin by a lock stitch horsehair suture. A moist corrosive sublimate dressing is applied, and the testicle held elevated by a scrotal support. The dressing should be performed the day following the operation and the drain started. Except in cases where suppuration is considerable, it is rare that the wound needs irrigation. A supporter should be worn for several months. The urethral discharge occasionally stops with the involvement of the epididymis and does not return. If, however, the urethritis is still present or returns, it should receive appropriate treatment after the acuteness of the inflummatory process in the epididy-

2. Expert Testimony.—Cumston observes that the work of the medical expert is a particular form of evidence, which should not be confounded with other forms of evidence, properly speaking, but it is, in a way, analogous to other forms of evidence because it is based on the supposition of a presumed extraordinary knowledge offered by the physician appointed by the court to the medicolegal examination. From this it results that experts enjoy a particular function which should not be confounded either with that of the court, or, and especially, with that of the other witnesses. The part played by the medical expert should have a certain similarity to that of the jury, and, like the latter, the expert should be empowered to render his personal judgment upon the question; but this judgment should never be imposed upon the authorities who are to apply the law when the verdict of the jury definitely decides the question of guilt. As to the ordinary witnesses, they should differ totally from the medical experts, although in the courts of the United States there is no difference. It is the opportunity alone which creates the witness, namely, his fortuitous presence on the spot at the time of the crime; or, on the other hand, it may be his relations with the accused which necessitate his presence on the witness stand in order to relate what he may know directly or indirectly about the case. But the witness should only have a single duty, and that is to state what he has seen or heard, and he should not be asked to emit any thoughts that were suggested to him from what he saw or to offer any conclusions that he may have drawn therefrom. In other words, he should not have the right to emit any judgment on his own The expert, on the contrary, does not go about his mission from circumstances or chance. because, in a large majority of instances, his cognizance of the affair only results by his appointment to proceed as an expert; this mission is confided to him on account of his special knowledge and the power that this gives him to enlighten certain points which, without him, would remain obscure. The expert should then be the object of a choice, and his mission is twofold; it is not limited to the discovering of circumstances that the court would be unable to discern itself, and the expert should also give his appreciation of facts and draw conclusions from the knowledge he obtains from his capacity as expert. He should give his personal opinion to the authorities, and in this way he passes a judgment in every sense of the word. The author cites the European laws applying to expert testimony, and shows that the proposed New York State law is very similar to the European laws.

- Treatment of Epithelioma by Röntgen Rays, By G. E. PFAHLER.
- X Ray Uses, Dangers, and Abuses Ruptured Tubal Gestation. When Shall We Operate?
 By Hunter Robb.
- Tuberculosis in Children.—Hollopeter says that in dealing with tuberculosis in children we must

recognize an infectious disease that has no well defined incubating period. Latent tuberculosis may continue throughout the life of the child, and we must never forget the protean types of expression of tuberculosis during childhood. Thorough control of tuberculosis can only come when the public is taught that ill health, from whatever cause, is an open invitation to its infection. Anæmia, loss of weight, with gastrointestinal catarrh, are more certain early symptoms.

4. Labyrinthitis.—Davis states that in cases of acute labyrinth suppuration it is better and safer to remove the labyrinth at the time of the radical operation, although the facial canal remains intact, for it is in just such patients in whom the radical operation is done and the labyrinth is not removed that, after from twenty-four to forty-eight hours, suppurative meningitis and death occur. The best method of operation is to make wide exposures of the sinus and meninges, uniting the middle and posterior fossæ. It is advised that in cases of suppurative labyrinthitis it is far better to do no operation than to make the radical operation without at the same time operating on the labyrinth, since the radical operation alone exaggerates the pathological conditions in the labyrinth and thereby enhances the danger of meningitis.

5. Tuberculin Tests.-Lincoln finds from her experiments and observations that the proportion of positive reactions to the von Pirquet tuberculin test, the conjunctival tuberculin test, and the tuberculoopsonic index, are substantially the same, ranging from eighty to ninety per cent. in favorable cases, and from thirty to forty per cent. in unfavorable cases. The more advanced the disease the smaller the percentage of positive reactions. The intensity of the reaction does not consistently follow any rule, but tends to be greater in cases of less advanced dis-The von Pirquet tuberculin test seems harm-The conjunctival tuberculin test should be used with caution. Until we can use the tuberculin tests with more intelligence than our present experience makes possible, we should make more comparative tests in all stages of the disease.

6. The Treatment of Epithelioma by Röntgen Rays. — Pfahler observes that early superficial epitheliomata involving the skin of the face and the back of the hands, when treated early by means of the Röntgen rays, should give good results in practically all cases. These results are brought about painlessly, with the lest possible scarring and often with none, and they are probably more likely to be permanent than the results from treatment by any other method. Epitheliomata associated with senile keratoses yield to Röntgen rays rather easily, but there is more likelihood of recurrence. Deep ulcerating epitheliomata with indurated fibrous bases do not yield good results under this treatment and should be excised when possible. When this is not possible, the rays will often give relief of pain, lessen discharge and prolong life. Epitheliomata involving the mucous membrane of the lower lip and cheek should be excised, and the excision followed by treatment of the glandular area with the Röntgen

7. X Ray Uses, Dangers, and Abuses.-Gottheil gives a good résumé of the uses, dangers, and abuses of the x ray: The x ray is a remedy of positive, though strictly limited, value in dermatology. It is to be used with caution, since its dosage is unmeasurable, the individual reaction to it is unknowable, and its results uncertain in any given case, and it should be employed only in the more serious dermatoses in any case, and in these only when it is entirely certain that safer and simpler means of cure are ineffective. It is not suited for use by the general practitioner in dermatotherapeusis, but should be employed in this field only by those whose familiarity with the method and with dermatology as a whole is a guarantee of certainty of diagnosis and of the observance of all the cares and precautions prescribed by experience. The x ray should not be used in the treatment of eczema, psoriasis, acne, alopecia areata, alopecia prematura, pruritus, hypertrichosis, folliculitis, verruca, ordinary ringworm, favus, etc., all of these being maladies for which we possess other efficacious therapeutic measures. In lupus erythematosus it is conceded to be useless. Epithelioma and rodent ulcer, except when so far advanced or so situated as to be unsuited for caustics, the curette, or the knife, is also to be excluded from the list. It may be used in lupus vulgaris, though it is not he only method of cure in many cases; in scrofuloderma on account of the tediousness and uncertain results of other medication; in very extensive cases of ringworm of the head and beard for the same reasons. The x ray is treatment of election in epithelioma and rodent ulcer so situated that other methods of treatment can not be employed, or so extensive that other methods are hopeless, and in relapses after other methods; in tuberculosis cutis, erythema induratum, and some other tuberculides; in sarcoma, mycosis fungoides. rhinoscleroma, keloid, and acne keloid, in which diseases no other method has given as good results.

8. Tubal Gestation.—Robb remarks that not more than five per cent. of the victims of ectopic gestation die at the time of rupture, whereas after the immediate operation in 1,176 cases in 25 clinics the mortality was eight per cent. When a patient is seen in a state of collapse as the result of a ruptured ectopic sac, she should not be operated upon until the condition of shock has been tided over, as these patients, when they die, rarely if ever succumb from loss of blood alone, but mainly from shock. Some of the reasons for believing that the hæmorrhage is not so great as has been generally supposed at the time of the rupture are as follows: (a) The great majority of ectopic sacs rupture between the first and third week of gestation. (b) The point at which the impregnation takes place is in a small area formed by a diverticulum in the tube, and the chorionic villi have only a feeble attachment. (c) From seventy-five per cent. to seventy-eight per cent. of the ruptures occur through the fimbriated end of the tube, and are tubal abortions not more dangeroccurring through the cervix. (d) The next most frequent place of rupture is the isthmic portion of the tube, which is also free from any large bloodvessels, (e) The point of rupture in the gestation vessels. (f) As a result of the inflammation which precedes the ectopic gestation, there is a relative increase of the connective tissue in the tube, and owing to the contraction of the connective tissue the vascularity of the tube is limited. (g) The placenta is generally attached to the posterior wall of the tube, and as the rupture is generally through the anterior or lateral wall of the tube, the placenta is not lacerated, but retains its firm attachment to the wall of the tube and is subjected to pressure. Physiologists teach that a woman weighing 130 pounds must probably lose four pounds of blood before succumbing to the effects of the hæmorrhage per se. So large an amount of blood is rarely found in the abdominal cavity-the sanguineous fluid is a mixture of blood and a serous exudate. The sudden removal of a large quantity of recently accumulated fluid in the abdomen, before the other vessels have had time to adapt themselves to the altered mechanical conditions, is dangerous and may be followed by fatal syncope. Patients in whom the bleeding would be sufficient to cause death are rarely seen in time to be saved by an operation for ligating the bleeding vessel. Our best operators give a proportion of forty or fifty per cent. as their death rate after immediate operations during shock. The results obtained by not a few good operators who have waited and carried out the deferred operation are certainly worthy of consideration.

 By MILTON R. BARKER.
- Three Very Unusual Cases of Appendicitis,
 By C. W. TRUEHEART.
 Clinical Observations on Malaria on the Isthmus of
 Panama. (Preliminary Note), By W. E. DEKS.
- 2. Obstinate Vomiting in Infants.-Northrup says that a nursing baby may vomit because its food enters the stomach too rapidly and consequently in too great quantities. The causes of this overdistention may be sought in the large quantity of breast milk, easy flow, large nipples, vigorous nursing. These conditions may be overcome by imposing mechanical obstructions, "drinking uphill," being here suggested. In his cases the successful position was, sprawling head downward and face downward over the mother's shoulder to the nipple, like a squirrel coming down a tree.
- 5. Pancreatitis .- Barker remarks that the aim of treatment in all cases of pancreatitis is to undo that which disease has done, by restoring as far as possible the pancreatic and biliary secretions to their normal functions as digestive fluids, and preventing as far as possible the drainage of the pancreas and liver into the blood. Whenever systemic and local conditions are such as to make us suspicious of pancreatitis, and Cammidge's test is positive, we should not hesitate to advise operative measures as the best

procedure in the case. Our object should be to increase as far as possible the excretion of bile and pancreatic secretion through their natural channels. This is best accomplished by removing all gallstones and débris from the gallbladder and gallducts and by dilating the common duct and papilla by the passing of proper instruments through them into the duodenum. A complemental drainage should also be established, by doing a cholecystoduodenostomy. By this manœuver drainage for both bile and pancreatic secretions is afforded through the cystic duct and gallbladder into the duodenum. Thus the bile is at once restored to its proper function, and at once the blood is relieved from its vicious effects. The operation also affords a better drainage for the diseased pancreas, by enlarging and clearing its natural outlet, and giving it two avenues for drainage instead of one. If for any reason this cannot be done, external drainage of the biliary and pancreatic ducts through the gallbladder should be maintained for a considerable time. Chronic pancreatitis entails a long and painful invalidism, but seldom of itself terminates life. It, however, so enfeebles the system that it becomes an easy prey for acute conditions of every nature, and life is usually terminated by some of these.

2. Chromocystoscopy. — Brook states that chromocystoscopy, or the introduction into the blood current of pigments which are excreted by the kidneys, and the observation by means of the cystoscope of their elimination by the ureters, as an aid to the diagnosis of renal disease, is not a new procedure. Methylene blue was the substance first used, but it gave uncertain results, as a large quantity is converted into and secreted as a colorless product. Sodium sulphindigotate (indigocarmin) is the substance now used. It is absolutely harmless, is entirely excreted unchanged, appearing in the bladder from twenty to thirty minutes after being injected. and is mostly eliminated in about two hours. The pigment particles are eliminated solely by the actively secreting structures of the kidney—the epithelium of the uriniferous tubules-and not at all by the filtering apparatus, the glomeruli, and malpighian cap-About a drachm of a four per cent. solution freshly prepared with sterilized water is injected into a muscle. The solution itself must not be boiled or it becomes gelatinous. It is as well to give a diuretic or a large quantity of water shortly before the examination, as otherwise the commencement of excretion may be much delayed. If general anæsthesia is not being employed, the urethra and neck of the bladder are prepared in the usual way with cocaine.

The examination is conducted in urine if this is clear and has not been too deeply stained by pigment already excreted, otherwise in boracic lotion or sterilized water. Upon cystoscoping the bladder half an hour after the injection, jets of blue urine are seen to issue alternately from each ureteral orifice, spreading out in a thin cloud towards the base of the The more distended the bladder, the finer bladder. and more forcible are the jets. Chromocystoscopy is much simpler than cystoscopic catheterization or separation by means of Luys's instrument.

5. Cancer in India.—Bentall has studied cancer as it occurs in Travancore in Southern India, and reaches the following conclusions: 1. The younger age incidence of cancer in Travancore is suggestive of some definite cause early in life. 2. Frequence of cancer of the buccal cavity and absence of it in the rest of the alimentary canal is suggestive of a local cause for the former, but absence of digestive causes in the latter. 3, The inveterate habit of "betel chewing" from childhood is suggestive of the cause, either by mechanical irritation or a medium suitable for the growth of a possible cancer germ.

By H. TILLEY. trative Cases On a Remarkable Case of Venous Accommodation after Compression of the Superior Longitudinal

Sinus by a Glioma, By L. P. PHILLIPS and G. E. SMITH. "Sutika," the Puerperal Diarrhœa of Bengal,

By F. PEARSE. The Palliative Treatment of Inoperable Cancer. With Remarks upon Certain Recent Developments in Therapeutics Considered from a Chemical Standpoint, By H. L. Drage and G. T. Morgan. The Royal College of Surgeons of England,

By H. MARSH.

1. Massive Collapse of the Lung.-Pasteur states that massive collapse of the lung is always due to paralysis of the respiratory muscles, especially the diaphragm. The lower lobes are the parts of the lung affected, the right base suffering more than the left. It is proverbially difficult in many cases of disease within the chest to decide whether the physical signs presented are due to compression, consolidation, or collapse of the lung. The signs usually observed in massive collapse are loss of percussion resonance sometimes amounting to actual dulness, with weak breathing which is often bronchial or tubular. Œdema râles may also be present, or crepitations when there is associated pneumonia. The most important diagnostic indication is the association of paralysis of the muscles of respiration. for massive collapse apparently never takes place in its absence. A very early and important indication of diaphragmatic failure is exaggerated action of the lower ribs. Massive collapse only occurs when the paralysis is profound and of rapid onset. Whenever the loss of respiratory muscular power falls short of this point there is a deficiency of lung expansion exactly proportionate to the loss of muscular power.

it may lead to the deflation of a whole lobe, is always caused by obstruction in some part of the air passages. Massive collapse is essentially an active process, lobular collapse a passive one, for the former is brought about by the active exercise of the elastic property of the lung, whilst the latter is caused by a passive removal of the air from portions of lung which have been cut off by bronchial occlusion from communication with the external air. Failure of the diaphragm to expand the bases of the lungs is in some cases responsible for the chest complications which sometimes follow severe operations. In a large majority of cases these lesions follow operations on the abdominal cavity, and the bases of the lungs are peculiarly liable to be affected. Long continuance of the Trendelenburg position is probably harmful by causing visceral pressure on the diaphragm. The writer's operations in laparotomy cases show that there may occur reflex inhibition of the movements of respiration of sufficient intensity and duration to cause massive collapse of the lungs. The symptoms presented very closely resemble those of pneumonia, and it is not unlikely that some of the cases diagnosticated as postoperative pneumonia are in reality

cases of massive collapse.

2. Angeioneurotic Œdema. — Whiting states that of all the angeioneuroses—acroparæsthesia, Raynaud's disease, erythromelalgia, intermittent hydrops articulorum, and angeioneurotic œdema-the last alone can be said to be dangerous to life. It gains an additional importance from the circumstance that with its possibly fatal result it is directly transmissible from one generation to another, even to the fourth generation and more. The disease, or rather the symptom complex of angeioneurotic ædema, is characterized by the occurrence of more or less sharply localized edematous swellings affecting the skin and subcutaneous tissues, the mucous membranes, and submucous tissues, and possibly other structures. They are chiefly found on the face and neck and uncovered parts of the limbs, but often involve the covered parts of the limbs, trunk, mouth, throat, genitalia, and gastric and intestinal wall. The condition probably affects also the intrapulmonary bronchi and possibly the central nervous system. The swellings develop to their full in a few hours and rarely last more than twenty-four hours. The skin may be reddened or not; there is no pitting on pressure, and usually neither itching, pain, nor tenderness, although a sensation of tenderness is not infrequently complained of. The condition probably affects also the intrapulmonary bronchi and possibly the central nervous system. The attacks show a cyclical recurrence in many cases. The average interval may be two or three weeks, but a month rarely elapses without an attack. Males are more frequently attacked in England and Europe; in America the reverse seems to be true. The age of onset is generally in early adult life. As with acroparæsthesia, the attacks most often occur in the early morning about three or four o'clock, when the vasomotor tone is normally at its lowest. Among recognized exciting causes of attacks are exposure to heat and cold and slight tissue injuries. A frequent manifestation of the condition is the occurrence of periodical attacks of severe intestinal colic, with sometimes nausea and vomiting. As previously stated, there is a marked hereditary tendency. Osler describes a family of thirty-six in five generations, of whom twenty-two had the disease. Very little is known as to the pathology of the condition. Among the causes assigned have been vasomotor instability, intestinal autointoxication, abnormal permeability of the bloodvessels, and localized venous spasm. Much might be advanced in support of its affinity with asthma and even with acute suffocative catarrh of the lungs. The distinctive diagnosis is simple: Certain cases might be confounded with atypical cases of urticaria. As to prognosis, when the swellings are limited to the skin there is nothing to fear as regards life, and there is some hope of recovery. Where the swellings affect the respiratory tract the prognosis is thoroughly bad as regards life, and particularly so in the family cases. Where junctions of skin and mucous membrane are affected, as in the lip or the cheek, the risk of spread to the throat must be taken into account. The gastrointestinal attacks do not seem to be in any way dangerous. From treatment. in the lack of a definite pathology, not much is to be expected. To counteract the lability of the nervous system the general health should be kept at as high a level as possible, and medicine such as iron, arsenic, and strychnine given as required. But the main treatment in the dangerous attacks is without doubt intubation or tracheotomy; and this idea pushed to its logical conclusion would seem to demand that every patient subject to, or threatened with, attacks of cedema of the glottis should constantly wear an actual or potential tracheotomy.

6. Inoperable Cancer.-Drage holds that surgical methods are a confession of defeat in connection with cancer, and he attempts to demonstrate that certain methods are the proper ones with which to treat the disease when the failure of surgery is complete. His methods are based upon the following working hypothesis, that it is necessary to make such an alteration in the blood as will increase the power of the human economy to starve the parasitic growth, to check the changes which are the result of the life of a parasite within the body, and to introduce an obstacle in the growth of fresh foci of dis-He began with sodium cinnamate, basing its use upon the fact that it produces considerable leucocytosis. The various drugs allied to this were investigated chemically, and at present he uses the following: Sodium orthocoumarate is given subcutaneously in the form of a twenty-two per cent. solution in water, in a dose of twenty-five minims up to thrice weekly. Either cinnamic aldehyde in doses of one minim in capsules thrice daily, or five grains of acetylocoumaric acid thrice daily, are also given, both after food. In order to reinforce the activities of these drugs it is necessary to apply a destructive agent to the growths. For this purpose antimonium oxide and copper oleate are used. No toxic effects have been experienced from the use of any of these drugs. The author reports a number of cases of inoperable cancer in which great benefit followed the adoption of this line of treatment. Death never occurs from sepsis, the patients dying gradually from exhaustion. Patients whom the treatment affects least are those who have been treated with Röntgen rays after operation, or who presented large masses of scar tissue as the result of

operation. The position which leucocytosis occupies with reference to the curative action of the remedies is necessarily a speculative one, and it is more than probable that it is an alteration in the serum which is the factor of the greater importance.

By P. REWIDZOFF.

I. Pathogenesis of Eclampsia. - Mohr and Freund assert that by their experiments they have demonstrated the existence of a specifically acting poison of the placenta, and thus have furnished an important support to the theory of a placental intoxication as the cause of eclampsia.

The Exciting Agent in Scarlet Fever .-Gamaleia alleges to have isolated the exciting agent of scarlet fever in the form of a microorganism belonging to a new class of colony forming animal parasites and called by him the Synanthozoon scarlatinæ. He has found it in the skin, the throat, the spleen, and the kidneys. Some of its forms correspond to the rosette like formations described by Mallory and the chrysanthemum flowers of Prowa-

4. Specific Neurotoxine.—Goldbaum states to have unequivocally shown the poisonousness of the

serum of guinea pigs immunized with emulsion of dog's brain for dogs. The coefficient of toxicity of this serum was so high that an injection of I c.c. per kilogramme killed a dog in one experiment, and in another the intracerebral injection of 0.3 c.c. per kilogramme had such a poisonous effect that the dog was removed from the table in a condition of coma and died within an hour. In another case the injection of 0.6 c.c. per kilogramme induced only a somnolence with no symptoms of irritation or of evil effect, and the dog remained perfectly normal. The clinical picture produced by this neurotoxic serum consists of somnolence, torpidity, convulsions, contractures, and finally paralyses in a comatous condition

7. Quality or Quantity.—Bornstein protests strongly against the belief that the welfare of the organism is dependent on its weight, and that quantity and quality are identical. Quality rather than quantity should be the aim in the production of tissue, and the former should never be sacrificed in the interests of the latter. Then he applies this to the effects produced on the human body by alcoholic drinks, and urges abstinence on the part of physicians.

8. Infection with Tubercle Bacilli by Way of the Gastrointestinal Canal.-De Haan repeated the experiments made on smaller animals on a large ruminant animal found in Java known as a Karbau. six years old, healthy, and previously tested with tuberculin without reaction. Material taken from a cow dead of tuberculosis was made into cakes and introduced into the stomach through a glass tube passed into that organ through a wound in the side. Three and a half months later the animal was found to be in a dying condition and was killed. Examination revealed no traces of tuberculosis in or about the intestinal tract, but there was a pulmonary tuberculosis with a complicating tuberculous

12. Concerning the Influence of Fulguration upon the Vitality of Cells,

By HOFFMANN.

1. Results of Surgery in the Treatment of Cholelithiasis.-Kehr gives in tabulated form the results obtained by the various methods of surgical intervention in cases of biliary calculi, and speaks

highly in favor of excision of the gallbladder with

hepatic drainage.

2. Orthodiagraphic Observations Concerning Changes in the Size of the Heart in Infectious Diseases. Exudative Pericarditis, and Paroxysmal Tachycardia.-Dietlen has observed acute dilation of the heart, apparently of toxic origin, most frequently in diphtheria, but also in scarlet fever, typhoid fever, acute polyarthritis, and other acute infectious diseases. The behavior of the heart in the course of a recorded septic disease was remarkable. At first the heart was somewhat dilated, gradually increased in size while the bodily weight grew less, and reached its maximum at the end of the third week of sickness. No clinical signs of myocarditis were present during this time. Then the size of the heart began to diminish while the bodily weight rapidly increased, and reached its minimum at the end of the seventh week, which was slightly below normal, and then increased again until it became of the size it was at the beginning.

3. Action of Römer's Pneumococcus Serum in Croupous Pneumonia.--May tabulates his observations made on twenty-eight cases of pneumonia treated with Römer's serum. His paper will be completed in a later issue, but one point may be noted: Of seventy-eight patients, twenty-eight were treated with the serum; in twenty-three per cent. of these the crisis was delayed until after the ninth day, in the others such a delay was present in only

16.6 per cent.

4. Carcinoma Ventriculi ex Achylia.—Alexander reports the case of a man, forty-seven years of age, who had suffered from dyspepsia for five years, and for three years had suffered from a trouble diagnosticated first as achylia gastrica, and then a large carcinoma developed at the fundus of the stomach. He believes that the achylia formed the basis of the development of the carcinoma.

5. Lumbar Anæsthesia.—Horrmann believes lumbar anæsthesia to be indicated in old, decrepit patients, in those with nontuberculous lung diseases, or heart disease, and in prolonged operations.

11. Vaginal Cæsarean Section.-Dührssen reiterates the statement he has heretofore made in favor of the vaginal Cæsarean section as the preferable operation in cases of contracted pelvis of the first and second degrees, and when the cervix is imperfectly dilatable.

On the Use of the Wax Tipped Catheter for Diagnosis of Kidney Stone in the Male, By WINFIELD AYRES. Some Therapeutic Uses of Active, Passive, and Coming Hyperaemia, By EDMUND PRICE FOWLER. Dysmenorrhea, By R. A. MURRAY. Acute Perforating Gastric and Duodenal Ulcer.

By ELLSWORTH ELIOT.

The Wax Tipped Catheter for Diagnosis of Kidney Stone.—Ayres says that it has been proved repeatedly on the operating table that stone in the renal pelvis presents difficulty of diagnosis. Latterly we have been greatly helped in our diagnosis by the x ray, but many experts willingly admit that calculus is not always shown when present, and on the other hand, shadows are sometimes demonstrated when no stone exists. Several years ago Kelly, reporting on the use of the wax tipped catheter, showed that it was a great aid in making a diagnosis when the x ray failed. The only instrument now made that can be used for this purpose is Brown's old model-the one with the projecting telescope. He has added to his model a special telescope for the wax tipped catheter. With this cystoscope it is possible with great care to introduce the wax tipped catheter into the bladder without its touching anything but water. From there on the method of introduction is the same as for direct catheterization. For coating the catheter Kelly uses one half olive oil with one half dental wax, but Avres prefers pure beeswax. This is soft enough to receive the impression of a calculus and is harder than Kelly's mixture and more easily handled. The catheter is threaded through the catheter chamber backwards until only the tip projects beyond the telescope and is placed on the table with the tips projecting over the table edge. The cystoscope sheath is passed and the bladder washed out through it; then the bladder is filled. The telescope with the catheter in place is passed through the sheath while the water is flowing from the bladder, the sheath being somewhat depressed so as to throw the telescope when it emerges from the sheath well up; then more water is put in the bladder. If care has been taken with the passage of the telescope, and if the catheter has been rotated so that the tip will be just in front of the lens, the tip will not have touched the sheath at all, and when the bladder having been filled and the light turned on, the tip inspected through the cystoscope will be seen to be perfect. The catheter is now inserted in the suspected ureteral orifice and slowly passed. If any tender area is detected its distance from the bladder should be located and then the catheter withdrawn and inspected. Or it may be passed to the renal pelvis before encountering any obstruction or tender area. The impression of a calculus on the wax may be a very slight scratch, or what is more usual, a deep gouge. The very slight scratch requires corroboration by other similar scratches, but the deep gouge is positive evidence of the presence of a stone. Impression by solid tissue is smooth and differs materially from that of a stone. However, a flattening out of the tip of the catheter requires several tests to prove that the substance hit is not the face of a calculus.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE. Meeting of November 5, 1008

The President, Dr. John A. Wyeth, in the Chair.

Surgery of the Bile Passages, with Special Reference to Final Results .- Dr. John C. Munro, of Boston, reported the after results of operations upon the biliary passages in cases that had come under his observation during the past five years, utlizing all except the more recent cases. The number of operations was something over 300, and the final results were known in 198, including the fatal ones. One hundred and twenty-two patients had reported to him as well and without any symptoms referable to the bile passages. He had lost track of 106 cases, but thought that from the nature of the lesions and

the operation employed it was safe to count on good results in the majority of these cases. In ninety cases of recovery jaundice was present, in fiftyseven cases it was absent, while it was not recorded in forty-six. There were all degrees of jaundice. One of the ninety cases in which jaundice was present, sixty-three were simple galibladder stone. In forty-three cases of this type jaundice was noted as absent. In the common duct cases, fourteen patients had jaundice and three had not. Jaundice had been present in three cases of pancreatitis for which the gallbladder was drained; in two others it had been absent. Jaundice was present in seven cases and absent in seven in which there was an operation for infection of the gallbladder or the ducts without stone. Jaundice was present in two cases of operation for adhesions alone. No note had been made regarding the presence of jaundice in the forty-six cases of recovery; nineteen of these patients were operated upon primarily for some gross lesion elsewhere, such as ulcer of the stomach, umbilical hernia, uterine fibroid, etc. In the cases of recovery the duration of symptoms might be divided into two classes-those of short duration, or under one year, and those of long duration, or over one year. There were forty-eight cases with an average of four months; five of these patients had symptoms of only a few days' standing. The cases of long duration averaged six years, while there were nine cases in which symptoms had been present for an indefinite number of years. Among the fatal cases there were twelve in which symptoms had averaged six months and fourteen in which the symptoms had lasted on an average nine years. In twenty-seven cases the condition of the pancreas was found to be pathological. Adhesions were present in 127 cases and absent in twenty-two. The postoperative complications most dreaded were those of the lungs and bronchi. In 200 cases of recovery, three patients had typical pneumonia, one had acute cedema of the lungs, one had bronchitis following acute phlebitis, one was septic, and ten had slight cough. When the gallbladder was functionless it was removed if the condition of the patient warranted it. If, however, the gallbladder was functionally active, or if only temporarily out of order and there seemed a reasonable hope of establishing its function, it was drained. In the patients reporting themselves as recovered drainage had been employed four times as frequently as extirpation. In the cases that they had been unable to trace, drainage had been employed a little less than three times as frequently as extirpation. In the entire number of recovery cases they had performed cholecystotomy 125 times, cholecystectomy thirty-five times, and choledochostomy twenty-six times. The patients who had a recurrence of symptoms were divided into four classes: (1) Those in whom the symptoms were due to some unrecognized lesion and not to the presence of stones; (2) those in whom the symptoms were secondary to adhesions following operations; (3) those in whom stones had been left behind at previous operations; (4) those cases in whom new stones had formed. In this series of cases there were ten in which stones had been overlooked. These patients were either troubled with a biliary fistula that would not close or a return of the symptoms for which the first operation had been performed. The overlooked stone was in the gallbladder or cystic duct in every instance except one. Stones might form anew, but this was a very rare occurrence; their presence in these cases had been due to lack of thoroughness at the time of operation. Six patients had been lost from toxemia or cessation of hepatic functions. These patients did not die from shock, but apparently from cessation of hepatic function. In cases where hæmorrhage was suspected they had given, at Dr. Leary's suggestion, 30 c.c. of rabbit's serum subcutaneously; in all these cases there was no tendency to hæmorrhage. They had used this method with jaundiced or purpuric patients for more than a year, and had not seen a sign of bleeding, and they felt that there must be some value in the method. Dr. Munro concluded that an analysis of their cases demonstrated: (1) That jaundice was present in a majority of all gallbladder cases at some time, and that in a large majority of common duct cases there was jaundice; (2) that in these cases the pancreas was not infrequently pathological; (3) that in a large majority of cases adhesions were present and might be the direct cause of symptoms; (4) that pulmonary complications were to be feared, but were less frequent than might be expected; (5) that cholecystostomy was normally a more suitable operation than cholecystectomy unless the gallbladder was definitely functionless; (6) that adhesions, a contracted gallbladder, or overlooked stones might cause a recurrence of symptoms; (7) that it was better to treat toxemia cases medically until the acute stage was passed; (8) that severe capillary hæmorrhage might possibly be controlled, to what extent was not yet determined, by the employment of fresh animal serum.

The Treatment of Biliary Disease as Determined at the Operation.—Dr. Howard Lilenthal read this paper, which will appear in a later issue.

Cholecystectomy versus Cholecystotomy.-Dr. JOHN F. ERDMANN presented this paper, in which he referred to an article published in the New York Medical Journal in 1906, in which he had said that the indications for cholecystectomy were perforation by trauma, ulceration other than that due to abscess or gangrene, obliteration or stricture of the cystic duct, chronic cholecystitis with thickened walls, atrophy, gangrene, acute suppuration, enlargement by dilatation (usually due to calculus obstruction, stricture, or angulations of the gallbladder), marked adhesions, hour glass contractions, chronic or recurring cholecystitis or cholelithiasis, and malignancy. Cholecystectomy was contraindicated where the bladder was apparently healthy in cholelithiasis and pericholecystitis, where there was perforation into other viscera, where difficulty of closure of the connection was great, where there were perforations in the suppurative variety, where adhesions were ex-tensive and where life would be jeopardized by radical interference, where extensive malignancy existed, and where a hurried operation was necessary to save life. Dr. Erdmann said that he had slightly changed his views since that time and was not so radical at present. The reason for this change was that occasionally one had to do a secondary operation upon the common duct, either for an overlooked stone or for a stone that had formed in the liver and

come down, necessitating either a choledochotomy or leaving the patient a chronic invalid in case the stone did not pass. If such a secondary operation became necessary, one had lost the anatomical landmark if the gallbladder was absent. In acute cases, where the patient's condition demanded a rapid operation and the bladder was gangrenous, a few minutes more occupied with the operative procedure would justify cholecystectomy, and the danger of infection, sloughing, and hæmorrhage would be removed with a smaller risk than one would take by leaving the diseased organ. Where the condition was grave and only a thickened gallbladder with infection was present, the bladder contents alone were removed; this step included cystic and common duct work if necessary. Where time and shock were not important factors he did cholecystectomy if the bladder wall was friable or very thick, the bladder markedly elongated and thick, with patches of gangrene or grayish white slough, a large area of gangrene, or complete gangrenous destruction. In acute cholecystitis, calcareous degeneration called for cholecystectomy. In cases of old, contracted gallbladder, acute cholecystitis demanded cholecystectomy, as they were smouldering foci for subsequent attacks. If the gallbladder was acutely in-flamed and distended, the walls not over thick or infiltrated, with no mucous membrane destruction by gangrene or ulceration, he was prone to drain. One should do the radical operation for ulcerative perforations of the gallbladder. One could only obtain finesse of judgment by experience with these cases. In cases of malignancy he was inclined to close the abdomen except where the invasion was very slight or where the growth removal would be so thorough as to warrant a prognosis of little danger of return. Out of 104 operative cases, there were twenty-six cholecystectomies and one case of death due to malignancy. There were fifty-three cholecystectomies with three deaths. They had a record of twenty-five cholecystectomies with no deaths, and fifty-one cholecystotomies with one death, excluding malignancy and a case of multiple abscesses, where death was inevitable. Some of these cases were associated with other operations, such as appendectomies, subphrenic abscess, and such conditions as pregnancy, and one case of hæmor-rhage in the second week post partum. There was one case of cholecystotomy with choledochotomy in which the patient recovered. There were twenty cholecystectomies with choledochotomies, with five deaths. Choledochotomy was done in four cases without any fatality. By excluding the three malignant cases and the one of multiple abscesses, the series contained 100 cases in which there were seven deaths, none of which occurred in twenty-five cholecystectomies and only one in fifty-one cholecystectomies.

Dr. JOSEPH A. BLAKE said that experience had taught him that many difficulties were to be encountered in operations upon the biliary passages. He had been much interested in what had been said regarding the use of rabbit's serum in arresting hæmorrhage. He thought that cholecystotomy should be done rather than cholecystectomy in the badly suppurating cases. In cases of walling off hy adhesions cholecystotomy was a very easy operation and could be done under local anaesthesia. The gallbladder could be removed later if it was found tobe necessary. Many gallbladders would recover if drained; for this purpose the simple rubber dam, carried down, acted very well.

Dr. Lucius W. Hotchkiss said that the cigarette drain was very effective as well as the simple

rubber dam.

Dr. ALEXANDER B. JOHNSON said that during recent years his experience with gallbladder diseases had been quite large, and he was in favor of removing the gallbladder in nearly all serious cases. He had had a number of cases of acute cholecystitis, some very severe, some gangrenous, some with complicating stone in the gallbladder which ob-structed the cystic duct. These patients had been operated upon by other surgeons, who had done cholecystotomy. When, subsequently, the removal of the gallbladder became necessary the operation was exceedingly difficult. He had seen a number of fistulæ following the drainage of the gallbladder. He had had only one case of fistula among thirty cholecystotomies during the past three years. In this patient the bile discharged for more than a year, and a second operation was finally performed.

Dr. George E. Brewer said that Dr. Munro's experience in finding sixty-three cases of jaundice with simple gallbladder stone was rather unusual; when the stones were limited to the gallbladder jaundice was exceedingly rare. Carcinoma of the gallbladder was very serious and was fatal even in the early stages. It was sometimes almost impossible to distinguish gallbladder disease from syphilis of the liver. This was a point that should be

borne in mind.
Dr. Willy Meyer asked whether, in cases of gallbladder stone, it was better to drain or to extirpate. He thought that, as the stones formed so rapidly, surgery should be thorough. If the gallbladder contained mucus it should be removed.

Dr. Elsworth Eliot, Jr., thought that where the cystic duct was damaged so seriously that there was danger of subsequent deformity which might incapacitate the gallbladder it was wise to perform cholecystectomy. The value of any operative procedure could only be judged by the results obtained.

Dr. Munro said that the gallbladder was not removed when it was performing its function, but if it was not able to resume its function it should be

taken out.

Dr. LILIENTHAL said that he believed that in simple gallstone disease, with no thickening of the walls and no infection, cholecystotomy should be the operation of choice. Wherever there was serious inflammation the gallbladder should be removed.

Meeting of November 10, 1003.

The President, Dr. John A. Wyerh, in the chair.

Medical Service in a Modern Army in War, as Exemplified by the Japanese Army in the Russo-Japanese War.—Major CHARLES LYNCH, of the Medical Corps of the army, delivered this anniversary discourse. He was the late representative of the corps in Manchuria. During the Russo-Japanese war he served as military attaché to the legation in Tokyo for duty with the Japanese army, to observe the work of that army. His service comprised the last ten months of the war, nearly all of which was spent at the front in Manchuria with the second Japanese army. Hostilities covered a period of some nineteen months; during this time both Russia and Japan had poured men into Manchuria, so that at the end of the war each had there between 750,000 and 1,000,000 men under arms. It was his purpose to tell as well as he could the reasons which enabled the Japanese to accomplish such noteworthy results.

The discussion of any medical department naturally fell under three heads, organization and administration, sanitation, and professional care of the sick and injured. In order that efficient service in war might be rendered by any military medical department, it was necessary that certain conditions be fulfilled. First, the medical department must be sufficient in numbers to perform the work required of it. The Japanese were extremely liberal in medical personnel. They found they required one per cent. of medical officers and nine per cent. of inferior medical personnel to the total fighting force. The Japanese recognized fully that the quality of their medical officers was quite as important as the number, and the inducements which they offered in pay and promotion for physicians to enter the army were sufficient to secure a good class of men. Russia, on the other hand, while she had a very few eminent surgeons, as a whole was far inferior to Japan in this respect. The Japanese medical department had complete autonomy and the Russian had not. In battle, aid to the wounded was given in various stages from front to rear. First, the regimental aided on the firing line and at the temporary dressing station, then at the dressing station, the field hospitals, the transport department for patients, the stationary hospitals, the line of communication hospitals, hospital ships, the receiving hospital at home, hospital trains, rest stations, and reserve hospitals with convalescent camps as branches. This was the Japanese organization. While the stream of wounded constantly ran to the rear and finally ended at home, medical supplies took the contrary direction. The battle of Mukden was the greatest of which they had record, lasting from February 26 to March 10, 1905, but the pursuit covered several days more. The Russians and the Japanese each had about 310,000 men engaged, the Russians having a preponderance of 300 field guns and 100 heavy guns, while the Japanese had 112 machine guns in excess of those in use by their enemy. Ten Russian corps occupied a front of forty-seven miles; the Japanese front was about forty miles in length. The Japanese losses were reported to be about 45,000 killed and wounded and the Russians had 273 officers and 8,626 men killed, 1,576 officers and 49,426 men wounded, and 336 officers and 31,-253 men missing, making a total of 2,185 officers and 89,305 men. Of the missing Russians, about 20,000 were made prisoners; the remainder were killed. The second Japanese army lost 5,908 killed and 16,288 wounded. The relative high loss in this army was due to the fact that it made a frontal attack on the strong Russian positions near Mukden. The temperature varied from zero to about 40° on the last days of the battle.

Major Lynch threw some lantern slides on the screen illustrating the medical department proper. From his brief account of the medical department in the battle of Mukden it was shown what an extremely complicated matter this was in a great battle. With all the thousands of wounded, and despite the heavy fire of the Russians, there were practically no wounded on the Japanese side who were not under shelter within twelve hours. This was the maximum time. This achievement of the Japanese medical department was simply marvelous. He showed pictures of a field hospital in operation between battles. The Japanese used no hospital trains in Manchuria. They did not have the necessary rolling stock, and even if they had possessed it, still they could not have permitted it to interfere with the supply of their troops. The Russians, on the other hand, had some fine hospital trains, so that a man might be transported very comfortably; but there were so few of these trains that usually Russian patients were put on any trains returning from the front, often without any provision being made for food or attendance. This was quite characteris-tic of the difference between the medical service of Russia and that of Japan. The latter always provided adequate though sometimes rough means for the care of the sick and injured. Before Port Arthur feli, Dalny had at times accommodations for 20,000 patients. Hospital ships were frequently loaded in two hours at Dalny and immediately started back for Japan. Japan operated twenty such ships during the war. Hirshima was the principal hospital centre in Japan. The Japanese provided accommodations for about 70,000 patients in their home hospitals, and for 10,000 convalescents in their convalescent camps. These men had every comfort and care which their country could supply

In all previous wars except the Franco-Prussian, on the German side, the deaths from disease had greatly exceeded those from wounds. The Japanese made use of the present day knowledge of sanitation, and in consequence protected their army better from the inroads of disease than had any other nation up to the present time. In the field army the Japanese reported one death from wounds to 0.47 from disease. While it would be highly desirable to contrast the results of the Japanese in this particular with those of the Russians, this could not be done, as the Russian statistics were worthless. He was quite sure, however, that the Russian percentage of loss from disease was at least twice that of the Japanese. While the Japanese attained notable success in preventing diseases of known causation or methods of spread, they failed with beriberi. A soldier who returned home in Japan suffering from a preventable disease was made to realize by his family and friends that he had been a credit neither to his country nor to them. This was a powerful factor in making soldiers observe the sanitary instructions given them, the correctness of which they would never presume to question. Moreover, a commander in Japan whose forces suffered from disease to an unwarranted extent was likely to be called upon for an explanation. The necessity of careful hygiene for the army was thoroughly impressed on all officers from the time they entered the service. It was taught in all the schools of the line officers, even in the staff college, the highest officers' postgraduate school in Japan. Soldiers received their instruction in hygiene almost entirely from the medical

officers of their regiments. Frequent sanitary inspections were made by medical officers of all grades in the Japanese service; sanitary faults, therefore, could not escape detection, and so they could be corrected before great harm had resulted. A monthly physical examination was made of all Japanese troops. This proved of value, not only as a means for weeding out the physically unfit, but also for detecting communicable disease. The clothing and equipment of the Japanese in every particular were excellent, except the shoes, which were the worst footgear which had been issued to an army in a good many years. Probably no army in a long campaign had been so well supplied with food at all times as were the Japanese in the Russo-Japanese war. Rice was their staple article of diet, and sugar was used to a considerable extent to increase the nutritive value of the ration. Cigarettes and sake were issued as a part of the ration. The standard establishment for the soldier's daily allowance of food was a minimum of 2,580 calories. On account of the prevalence of beriberi, one third of the rice was replaced with barley for some time during the winter of 1904. So far as Major Lynch could judge, this had no influence on this disease. Practically all water used by the Japanese in the field was sterilized by one method or another. Major Lynch believed that "all water was guilty until proved innocent." the field latrines were invariably pits, and their contents were well covered with earth or ashes. The habits of the Japanese soldiers were good. Drunkenness was almost unknown among them. Venereal disease was apparently common in China, but successful efforts were made to prevent the Japanese soldiers from cohabiting with Chinese women, unless they were regularly licensed, in the same manner as was done in Japan. Both love of country and love of family were used to effect this remarkable result. The Japanese probably bathed more than any other people. Even in the field the soldiers had their extremely hot baths, and it was rare that a day passed that each soldier did not get into the Chinese jars which they used for bath-

The Japanese regarded typhoid fever and dysentery as contagious diseases, and isolated them just as carefully as they did smallpox. This was believed to be necessary in an army where the opportunities for contact were so numerous. Lynch was firmly convinced that any army which detected such cases as early as the Japanese did, and then isolated them, would succeed in cutting off one very serious source of danger. The Japanese recognized the possibility of infection by No measures could be taken to prevent the millions of flies in Manchuria from coming in contact with fæcal matter. The army was compelled, therefore, to rely on preventing flies from having access to their food by serving it only immediately before it was to be eaten. The Japanese, in addition to the excellent methods which he had already described to prevent water borne diseases, thought they could diminish their frequency by the use of an intestinal antiseptic, and a creosote pill was issued in little tin boxes on which was written: "To defeat the Russians, take one pill three times a day." By thus appealing to the patriotism of the

soldiers there was no doubt that the pills were taken regularly. It was believed that the medical department made a bad error on this subject of intestinal antiseptics. Very roughly, the Japanese might be said to have had about once case of typhoid fever and dysentery to the Russians six. Typhus fever, though quite common in Manchuria, was rare in the army. Tuberculosis was not commonly seen in the army. Smallpox was rare. Diphtheria, scarlet fever, mumps, and measles occurred only in isolated cases. Beriberi proved a terrible scourge to the Japanese army, and probably from forty to fifty per cent. of all the deaths resulted from it. The Japanese had stated officially that in peace 0.44 per cent. of the army had beriberi; in the Chinese-Japanese war this percentage rose to eighteen, and in the Russo-Japanese war it reached sixteen.

Major Lynch believed that beriberi was not a dietetic disease, and he was convinced that careful isolation of the cases and the proper measures of disinfection could be depended upon to prevent its spread. He ascribed the great increase of this disease in the Japanese army in war in great part to the extreme crowding of the barracks and other quarters, which gave every opportunity for infection from man to man. The success attained in protecting the health of the troops was due to the efficient application of the recognized rules of scientific sanitation. The Japanese, excellent organizers, administrators, and sanitarians as they were, could teach Americans nothing on the practice of medicine and surgery. The Russian medical department was, contrary to the Japanese, a very uneven organization. The Japanese returned a large percentage of sick and wounded men to the ranks. The most interesting cases seen were those of false aneurysms, osteomyelitis, and repairs of deformities. Neither Japanese nor Russians benefited to the greatest possible extent from the first aid packet. The packet of the former was too small, badly folded, and easily contaminated in handling; while with the latter but a small percentage of men were supplied with a better packet.

A medical department might be utilized to increase the offensive power of an army in two ways: First, the strength of an army was not dependent on the number of men on the rolls, but on the number actually on the firing line. "Where are my lost legions?" might be the cry of every commander, unless good sanitation was insured by an efficient medical depart-Second, unless the medical department of an army was so organized and administered that combatants on the firing line were given prompt attention, this line would melt away by unhurt men leaving it to assist their wounded comrades to the rear. At all times both during and between battles, the medical department should guard against unjustifiable loss to the front, by not permitting any men whose physical condition did not demand it to go to the rear. The Russian army, though hampered by bad organization and administration, undoubtedly made a fairly successful attempt to fulfill its humanitarian obligations toward the sick and injured, but it almost totally failed in increasing the efficiency of the army as a fighting force by the aid of its medical department. In fact, it hardly seemed probable that the Russian military authorities gave much thought to the latter subject. It would be going too far to say that this was the cause of the defeat of the Rus-

sians by the Japanese. It was, however, one of the factors which contributed to that result, and not the least important. It seemed to him that if they desired to profit by the experience of the Japanese they should recognize, first, that they must have a strong framework of medical officers on which to erect a structure which would bear the weight of war. The only way to attain this result, in his opinion, was by the creation of public interest and sentiment. So far as good sanitation for our army was concerned, greater difficulties were labored under than in Japan. The Japanese recognized that good sanitation depended in good part on the good teaching of personal hygiene to the individual officers and men making up their army, and with them this was a comparatively easy matter, as their war army, while much greater in size than their peace army, was made up from the active and reserve lists of the regular establishment only, and all officers and soldiers were in consequence well instructed in hygiene from the beginning of the war. America, on the other hand, had but a small army in peace, which must be augmented to a great extent by absolutely untrained men; so if Americans expected to rival the Japanese in low morbidity rates in war and so be efficient so far as these causes had an effect, Americans must go widely outside the army in teaching personal hygiene. This could only be done by good instruction in personal hygiene in schools. This really meant the instruction of a people. It was unnecessary to point out how much this would benefit the public generally in peace.

From what he had said he did not wish to have his hearers carry away the idea that a great deal had not already been accomplished by the medical department of the American army. The military forces to-day were in a stage of transition, but were gradually approaching a logical organization. They had been terribly hampered by lack of medical personnel, and in order to correct this condition they labored four years to have an act passed entitled "A Bill to Increase the Efficiency of the Medical Department." Last year this was done, and since then it had been possible to devote more attention to progress in other

directions.

Retters to the Editors.

MEDICINE AND THE CHURCH.

37 WEST FIFTY-FOURTH STREET, NEW YORK, November 16, 1908.

To the Editors:

In commenting editorially in the last issue of the Journal upon a letter of mine directed to the New York Times you say: "It is impossible to deny the truth of the greater part of Dr. Collins's contentions, but we may rise above their pessimism." May I ask you kindly to say to me what indication of pessimism there was in my letter? Surely, I took no pessimistic view of the prospects of the medical profession. Its outlook was never so promising, if one may base a judgment upon its achievements of the past twenty to thirty years. You further say: "It may be remarked that Dr. Collins underrates the activity of the Episcopal Church in the establishment of hospitals and kindred institutions for the relief of the sick and

injured in New York; St. Bartholomew's Clinic is by no means the sole or even the chief manifestation of that activity-witness, to mention only one, our magnificent St. Luke's Hospital. He appears also to ignore the immense medical work done under the auspices of the Church of Rome, the Presbyterian Church, the Methodist Church, and other Christian bodies, besides the Jews in their religious rather than in their racial capacity." I am at a loss to understand how you can construe the following (taken from my letter to the Times) so as to make it appear to have the significance that you have given it: "It is gladly admitted that the Church has built hospitals, dispensaries, and clinics; that she has carried the sick to the physician or taken physician and nurse to the sick; that she has provided summer homes for the poor. If by the Church Dr. Batten means the Roman Catholic Church, the Salvation Army, and the Jewish people, they certainly have done it." Is there anything in this sentence that permits you to say that I ignore the immense medical work done under the auspices of the Church of Rome, the Jews, etc.? Further, I would kindly ask you to point out to me wherein I have maintained that St. Bartholomew's Clinic is the *sole* manifestation of the activity of the Episcopal Church. I said: "If Dr. Batten means by the Church the Episcopal Church, then it must be denied that it has done all these things (meaning those enumerated above) to such an extent that it is justifiable to boast of it. Except in isolated instances, such as St. Bartholomew's Clinic, the Episcopal Church has done singularly little from the point of view of its wealth and position in this direction. And, Mr. Editor, I should like any one in good faith to try to controvert that statement. If you gather from that that I am ignorant of the existence of "our magnificent St. Luke's Hospital" or of St. Mary's Free Hospital for Children even, I hasten to assure you that I had a knowledge of their existence at the time when I penned that remark, the truth of which I still maintain

I have no desire to enter into controversy with the Worcesterites. My letter to the *Times* was for the purpose of attempting to show that physicians were more legitimately entitled to practise medicine than clergymen; that the assumption of the function of the practitioner of medicine by the latter profession was arrogant and unjustified; that Worcesterites had no corner on cheerfulness, hope, courage, faith, and prayer; and that it was ungracious of them to scoff at their parent, Mrs. Eddy.

JOSEPH COLLINS.

Book Rotices.

We publish 'all lists of Looks received, but we acknowledge no obligation to secure them all. Nevertheless, so far as space formits, we receive those in which we think our readers are likely to be interested.]

Guide du médeen confiste dans les accidents de travail Par le Dr. Calli ven, Assistant-adjoint d'ophthalmologie des hópitaux de Paris. Paris: Jules Rousset, 1908

The bulk of this little volume is composed of a survey of the relations of physicians to French insurance companies, tables of statistics, reviews of

decisions of the French courts, and synopses of contested cases, which render it naturally a more valuable medicolegal work in France than elsewhere, although it contains a good many points of general value. The chapters devoted to the examination of persons suffering from occupation injuries of their eves and to advice as to their care are of more general interest and suggest some valuable matters of detail.

Beiträge zur Enstehung der Geschweiter Dritte Ergänzung zur Geschwulstlehre für Aertze und Studierende. Von Hugo Ribbert, ordentlicher Professor der allge-meinen Pathologie und pathologischen Anatomie, Direcktor des pathologischen Institutes in Bonn. Mit 19 Abbildungen. Sechs beginnende Karzinome der Gesichts-Mit 19 haut eines Mannes. Bonn: Friedrich Cohen, 1908. Pp. 31.

This booklet is an addition to the author's Entstehung des Karzinoms, Bonn, 1906 (see New York Medical Journal for July 6, 1907, page 31). Professor Ribbert reports a case of six beginning carcinomata of the skin of a man's face. The examinations of these cancer formations seem to be in favor of his formerly promulgated theory that the carcinoma derives its origin from a subepithelial cellular change of the connective tissue, forming a growth of the lower cell layer of the epidermis, which growth invades the tissue below the epidermis, similar to the formation of lympathic glands. But this change also stops the epithelial spores from adapting themselves normally, as lympathic glands or hair follicles do, to the epithelial tissue, and induces a permanent hypertrophy, which finally results in an isolation from the normal tissue of a specific growth, thus forming a carcinoma.

Hay beter, Hay Asthma. Its Causes, Diagnosis, and Treatment. By WILLIAM LLOYD, Fellow of the Royal College of Surgeons, etc. Second Edition. London: Henry J. Glaisher; Chicago: W. T. Keener & Co., 1908. Pp. 101. (Price, 4s, 6d.)

The second edition of this book contains little that is new. The author describes the various theories concerning the cause and nature of hay fever that have been advanced in the past. He is inclined, we think, to lay more stress on pollen than is warranted, and less on the neurotic element in the evolution of the complaint than is reasonable. It seems to us that the latter is the essential feature of the affection, and that any irritating substance, e. g., pollen, will start the attack.

In the description of the treatment we think too little prominence is given the place of adrenalin solutions, which give certain patients great comfort, without the danger of producing subsequent deleterious effects. The evil influences of cocaine are properly set forth, but there is not a positive enough condemnation of the use of the drug. The treatment with pollantin is properly discouraged. The work ends with the publication of the histories of twenty-six cases.

Die Orthoröntgenographie. Anleitung zum Arbeiten mit potablehen Rosteenstraden Mit 32 Abhildungen Von Dr. Franz M. Groedel, Bad Nauheim. München: J. F. Lellmann, 1908. Pp. 76.

The importance of the parallel Röntgen rays has lately been fully recognized. This is also shown by the number of publications of pamphlets and of textbooks on Röntgen ray technology which treat of this subject.

Orthoröntgenography, and especially orthodiagraphy, is of great value for medicine, but the technique is rather difficult. The author's book will therefore be of help to every physician interested in this great adjuvant to diagnosis. The book gives a good introduction to the study of röntgenography and the general orthodiagraphical technique, and then describes orthodiagraphy as adapted for examinations of the heart, lungs, and abdominal cavity, and finally speaks of the orthophotographical technique of different authors, and their results as compared with orthoröntgenography, the use of which, in the author's opinion, with some exercise can be easily acquired, as it is a technically exact science upon the reproduction of which we may absolutely rely.

Diät-Vorschriften für Gesunde und Kranke jeder Art. Von Geheimem Medizinalrat D. J. Borntraeger, Regier-ungs und Medizinalrat in Düsseldorf. Fünfte verbeşserte und erweiterte Auflage. Würzburg: Curt Kabitzsch (A. Stuber's Verlag), 1908.

These diet directions are very practical. There are samples of thirty-nine different directions, such as rational diet for healthy people, diet during an epidemic of cholera, during the lying-in period, during fever, in acute nephritis, in affections of the heart, in anæmia, in convalescence, in rheumatism, and for patients with gallstones, etc. The directions are usually of two kinds, for the well to do and for the poor.

The physician can order from the publishers any form he wishes to use according to the number attached to the directions, and can then give these directions to his patients as the occasion may arise, thus avoiding oral advice, which is often forgotten or misunderstood. The directions are plain, avoiding unnecessary scientific explanations which cannot be understood by the average layman. An English edition for the American physician would certainly be well received.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the fourteen days ending November 11, 1908

- Abbott, F. C., Acting Assistant Surgeon. Leave of absence for fourteen days granted October 13, 1908, amended to read seven days from October 11, 1908.
- ALEXANDER, E., Acting Assistant Surgeon. Granted four-teen days' leave of absence from November 6, 1908.
- Bailey, C. A., Acting Assistant Surgeon. Directed to proceed to St. John, N. B., on or about November 19, 1908, for medical examination of aliens.
- BILLINGS, W. C., Passed Assistant Surgeon, Directed to proceed to Arundel Cove, Md., and report to commanding officer of the revenue cutter Itasca, for duty.
- BRINCKERHOFF, W. R., Acting Assistant Surgeon. Directed to proceed to Molokai Leprosy Investigation Station as often as the public business requires.
- CARTER, P. I., Acting Assistant Surgeon. Granted seven days' leave of absence from October 26, 1908, under paragraph 210, Service Regulations.
- CLARK, TALIAFERRO, Passed Assistant Surgeon. Reassigned to duty at Philadelphia, Pa., to date from July 19, 1908; directed to proceed to Schuylkill Haven, Pa., for the purpose of examining an insane alien; directed to proceed to points in Pennsylvania, New Jersey, and Delaware, for the purpose of making medical examination of aliens
- FAHEY, EDW. W., Acting Assistant Surgeon. Granted nine-teen days' leave of absence from November 12, 1908.
- FISHER, C. E., Acting Assistant Surgeon. Granted ten days' leave of absence from November 6, 1908.
- Frost, W. H., Assistant Surgeon. Upon being relieved by Passed Assistant Surgeon W. C. Billings, directed to proceed to Washington, D. C., and report at Hygienic Laboratory for temporary duty.
- GILL, S. G., Acting Assistant Surgeon. Granted twentyeight days' leave of absence from December 4, 1908.
- GOLDTHWAITE, HENRY, Acting Assistant Surgeon. Granted twenty-one days' leave of absence from November 5,
- GRUBBS, S. B., Passed Assistant Surgeon. Directed to proceed to New York upon completion of duties in Paris,
- Gustetter, A. L., Acting Assistant Surgeon. Granted ten days' leave of absence from November 15, 1908.
- HUGHES, C. W., Acting Assistant Surgeon. Granted thirty days' leave of absence from Novemebr 5, 1908.
- Hume, Lea, Acting Assistant Surgeon. Granted ten days' leave of absence from October 24, 1908; granted ten days' extension of leave of absence from November 3, 1008.
- JACKSON, JAMES M., JR., Acting Assistant Surgeon. Grant-ed thirteen days' leave of absence from November 9, 1908, and eight days' leave of absence, without pay, from November 22, 1908.
- KIMMET, W. A., Acting Assistant Surgeon. Leave of absence for thirty days, granted September 16, 1908, amended to read twenty-five days from September 20, T008.
- LATINDER, C. H., Passed Assistant Surgeon. Granted two days' leave of absence from October 30, 1908, under paragraph 191, Service Regulations.

 LYALL, R., Acting Assistant Surgeon. Granted three days'
- leave of absence, without pay, from November 3, 1908.
- NUTE, ALBERT J., Acting Assistant Surgeon. Granted one day's extension of leave of absence, on account of sickness, November 6, 1908.
- ONUF, B., Acting Assistant Surgeon. Leave of absence for twenty-seven days from November 1, 1908, granted October 22, 1908, amended to read twenty-seven days from November 4, 1908.
- Ryder, L. W., Pharmacist. Granted four days' leave of absence from November 2, 1908; granted two days' extension of leave of absence from November 6, 1908. SCHERESCHEWSKY, J. W., Passed Assistant Surgeon. Reassigned to duty at Baltimore, Md., to date from November 2, 1908.
- vember 2, 1908.

 Stoner, Geo. W., Surgeon. Granted five days' leave of absence from October 23, 1908.

STILES, C. W., Chief Division Zoology, Hygienic Laboratory. Detailed to represent the Service at the meeting of the Southern Medical Association, Atlanta, Ga., November 10-12, 1908.

Boards Convened.

Board of medical officers convened to meet at the Marine Hospital, Baltimore, Md., November 4, 1908, for the pur-pose of conducting a physical examination of an officer of pose of conducting a physical examination of an oliter of the United States Revenue Cutter Service; Passed Assist-ant Surgeon J. W. Schereschewsky, chairman; Passed Assistant Surgeon J. T. Burkhalter, recorder. Board of medical officers convened to meet at the Marine

Hospital, Seattle, Wash., for the purpose of examining alien Joseph Elia; Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chapin, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers serving in the medical corps of the United States Army for the week ending November 21, 1908:
Appel, D. M., Lieutenant Colonel, Medical Corps. Granted

Prepert, D. M., Lieutenant Colonel, Medical Corps. Granted leave of absence for thirty days.

Віярнам, W. N., Captain, Medical Corps. Ordered to report at Manila, P. I., for examination for promotion. Bloombergh, H. D., Captain, Medical Corps. Relieved from duty at Fort Leavenworth, Kan., and ordered to San Francisco, Cal., to sail January 5, 1000, for Manila for

Philippine service.

Cox, Walter, Captain, Medical Corps. Ordered to report

at Manila, P. I., for examination for promotion.

DOUGHERTY, JAMES C., First Lieutenant, Medical Reserve
Corps. Ordered to active duty at the expiration of his present leave of absence.

ESCOBAR, JULIUS A., First Lieutenant, Medical Reserve Corps. Fell into an open well at Imus, Cavite, P. I.,

November 15, 1908, and was drowned.

Geddings, E. G., Captain, Medical Corps. Ordered to report at Washington, D. C., for examination for promotion.

GUITTARD, A. M., First Lieutenant, Medical Reserve Corps. Ordered to active duty and directed to proceed to Fort Logan, Col., for duty. HARVEY, P. F., Colonel, Medical Corps. Left Chicago, Ill.,

on leave of absence.

Jones, H. W., First Lieutenant, Medical Corps. Relieved from duty as surgeon of transport Buford about Janu-

ary 15, 1909, and ordered to the United States.

MON, R., First Lieutenant, Medical Reserve Corps. Granted an extension of fifteen days to his leave of

MURRAY, WILSON, First Lieutenant, Medical Reserve Corps. Ordered to active duty at the expiration of his present leave of absence, and directed to proceed to Fort William Henry Harrison, Mont., for duty.

Persons, E. E., Captain, Medical Corps. Relieved from duty in Philippines Division; will sail December 15, 1908, from Manila for San Francisco.

PINKSTON, OMAR W., First Lieutenant, Medical Corps. Relieved from duty as surgeon of the transport Crook.

PURNELL, H. I., Captain, Medical Corps. Relieved from duty at Fort Mackenzie. Wyo., and ordered to San Francisco, Cal., for duty as surgeon of the transport Thomas on its next voyage; on arrival at Manila, to report for duty in Philippines Division.

QUINTON, W. W., Captain, Medical Corps. Ordered to report at Washington, D. C., for examination for pro-

motion.

RAGAN, C. A., Captain. Medical Corps. Left Fort Monroe,

Va., on leave of absence for ten days. REASONER, M. A., First Lieutenant, Medical Corps.

lieved from duty as surgeon of the transport Thomas.

SLAYTER, JOHN T. H., First Licutenant, Medical Reserve
Corps. Honorably discharged from the service of the United States.

WORTHINGTON, J. A., First Lieutenant, Medical Corps. Relieved from duty at General Hospital, Presidio of San Francisco, Cal., and assigned to duty as surgeon of the transport *Crook*.

CONTRIBUTION TO OUR KNOWLEDGE OF THE ETIOLOGY OF DEMENTIA PR.ECOX.*

(Preliminary communication.)

By Morris J. Karpas, M. D., New York,

Assistant Physician, Manhattan State Hospital; Deputy Assistant Neurologist, New York Hospital for Nervous Diseases.

CONTENTS.

I. Introduction.-A brief consideration of the various psychological theories underlying dementia

II. Governing atiological factors in dementia praco.r.—Heredity—autointoxication —seasons—age nationality-psychotic traits-education-sociological conditions and occupation-sex-previous diseases-masturbation-civil condition-pregnancy, childbirth, etc.-trauma - alcohol - prisons-infectious diseases and operations-emotional influences -no exciting determinants.

III. Concluding remarks.

Introduction.1

An attempt to explain the psychology of dementia præcox was made by many students of psychology and psychopathology-numerous fascinating theories resulted. In this paper only a brief reference can be given to them.

In 1886 Tschisch stated that the fundamental disorder of catatonia is insufficiency of attention. Freusberg maintained that the automatic actions in catatonia are connected with a state of weakened consciousness which lost its control over the psychic The motor disturbance is only a symptomatic expression for the grade of psychic tension. The fact that weakening of consciousness is dependent upon the disturbance of attention is also accepted by Aschaffenburg, Janet, Kraepelin, and Ziehen.

In 1894 Sommer in his studies on catatonia concluded that in this disease the perceptive processes are retarded, and the produced images often im-press on attention and the patient has great difficulty of getting rid of them.

Neisser stated that at the threshold of consciousness lie all the pathological conditions of stimuli.

Vogt, being influenced by P. Janet, thought that constriction of consciousness and reduction of attention are the main elements in catatonia. selon is of the same opinion. "Perception of external objects," he says, "perception of sound, perception of personality, judgment, and belief cer-

*Read in part before the Medical Society of the Manhattan State Haspital, February 28, 1908 *The main substance for the introduction was drawn from Jung's hook, Urbar Perchalogie der Promourer process, Jena, 1907.

tainly disappear when the intensity of attention diminishes." In regard to dementia præcox, Masselon affirms that "the habitual condition is an emotional apathy—the disorder is intimately connected with the disturbance of intelligence; they are of the same nature—the patients do not manifest any desires-the whole volition is much reduced-the disappearance of the desire is connected with all the other affections of mental activity—the elements have a tendency to revive an individual life, not being more systematized for an inactive spirit." Thus he assigns intellectual deterioration in dementia præcox to, I, attention disorder; 2, slowing of psychic process; 3, gradual decline of memory; and, 4, continuous diminution of power of combination. Briefly stated Masselon's theory implies a central psychological disturbance embracing cognition, emotion, and volition.

Weygandt made a special study of the end stages in dementia præcox, and he arrived at the conclusion that apperceptive dementia is its fundamental disorder.

Stransky, from the standpoint of clinical observation, concluded that "emotional deterioration in dementia præcox depends upon poverty or shallowness of emotional reactions and the incongruity between affect and ideation." He termed the latter condition as dissociation between thymopsyche and noopsyche. In his later studies he showed that speech disturbance is the product of intrapsychic ataxia.

Otto Gross explained the psychology of dementia præcox by dissociation of consciousness, and proposed a new name—dementia senjunctiva. savs: "Dissociation of consciousness, to my mind, signifies a synchronous discharge of functionally separate association streams." Upon this hypothesis the various abnormal mental phenomena such as autochtonous ideas, impulses, compulsions, and influences of the mind, could be explained.

Neisser believed that in dementia præcox there is a tendency to fixation of affect. "These fixations of affect destroy the ability to sympathize in joy or sorrow and lead to an emotional isolation of the patient, which goes hand and hand with intellectual

estrangement," remarks Neisser.

The studies in association methods have shed much light on the psychology of dementia præcox. Indeed such important work as Freud, Bleuler, Ricklin, and Jung cannot be too highly commended.

Jung, who followed Freud religiously and intelligently, offers a remarkable communication to the psychology of dementia præcox. Jung compares the mechanism of a dream to that of dementia præcox, and shows their intimate relations to each other. He says: "If we allow a person in a dream to

act or walk as if he were awake, then we have a clinical picture of dementia præcox." Again, "In dementia præcox a performed mechanism is loosened which normally and regularly functionates in a dream.'

The close analogy of hysteria to dementia præcox is pointed out by Jung; their essential differences may be briefly outlined. Hysteria is possessed by a complex which cannot very well be conquered. The wish dream, wish deliria, in hysteria are gratifications of the complex. There are several complexes in dementia præcox which have become permanently fixed and which cannot be suppressed. The causal relation between the complex and the disease in hysteria is conspicuous; but not such is the case in dementia præcox. However, analysis of many cases of dementia præcox clearly shows that their onset was caused by marked affectivity from which painful emotional states developed. In addition to the psychological action of the complex, it is also believed that toxines help its further activity. The psyche cannot liberate itself from the complex, and therefore personality becomes distorted. Jung says: "What Janet speaks of 'the function of the rcel' in hysteria may be applied to dementia præcox 'The patient constructs in his own imagination small, very coherent, and logical stories; that is when he comes in contact with reality he is no more able to effect attention than comprehension." In brief, Jung's theory of dementia præcox may be expressed in the following manner: A complex or detached thought content, associated with affective states, forces itself upon one's psyche and distorts personality by robbing "the ego of light and nour-ishment, just as cancer robs the body of its vitality." Hence we have a reduction of psychic energy, disorder of attention, lack of proper reaction and adjustment to and with environment, and the rise of morbid ideas.

Adolf Meyer's conception of dementia præcox is worthy of thoughtful consideration. In his own

We would ascribe as the essential features disruption of judgment, only insufficiently accounted for by any special mental or physical upset-that is, without any evidence of intoxication or other delirium, or without the manic depressive thinking disorder, or the foundation of the hysterical or epileptic disorder—discrepancies between the mood and the general reaction, peculiar attention disorders, and feeling of interference with thinking and deterioration in matters which are largely dependent on sound instinct, such as distinction of the real and unreal, and the critic of imaginative material—all this in the face of relative clearness. so that we are forced to think of a fundamental deterioraso that we are forced to think of a fundamental deteriora-tion or defect as the only means to account for so much perversion of instinct and reasoning. In connection with this there appear a number of symptom pictures, also met with occasionally as more or less adequate reactions, such as states of puzzle, of religious and mystic fascination, of automatic and stuporous states, such as can be in part obtained by hypnotic suggestion, or such as arise as psychasthenic and hysterical reactions, as we call them when they appear on sufficient and characteristic foundation. insufficiency of the provoking factor, and the oddity and incongruity rather than the mere excess of what might be the result of a sufficient cause in an average person, constitutes one of the most important criteria for the estimation of the seriousness of the process.

Despite these many magnificent explanations, we are still not able to interpret the morbid phenomena and genesis of dementia præcox. August Hoch

very thoughtfully remarks: "Dementia præcox is one of the most difficult problems of psychiatry, and it will be a long time before we shall be able to fully understand the symptoms and the principles which underlie them.'

It will be easily appreciated what a difficult task one undertakes to discuss the ætiology of a malady, the psychology and pathology of which are still obscure. Nevertheless, at the present state of our knowledge of psychopathology we have a right to restrict the group of dementia præcox to such cases in which the peculiar onset, stamps of deterioration, bizarre reactions, odd and unexplainable behavior, inconsistent emotional reactions, and the morbid ideas of a fantastic nature constitute a part or a whole of the disease picture.

The one hundred and thirty cases, selected for the purpose of study of the causative factors of dementia præcox presented the mentioned features.

THE GOVERNING ÆTIOLOGICAL FACTORS IN DE-MENTIA PRÆCOX.

Heredity.—No matter what theory of heredity we may accept, whether the Larmack's school, pangenesis of Darwin, germplasm of Weismann, plastidules of Haeckel, or Mendel's conception of transmission, the fact remains that hereditary influence plays an active part in the development of many forms of psychoses. Such eminent authorities as Morel, Dejerine, Magnan, Kraepelin, Ziehen, Biswanger, and others adhere to this view. The well known French dictum, "heredity is the cause of all causes," may be mentioned.

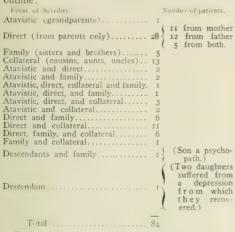

The relation of heredity to dementia præcox can However, Christian and hardly be disputed. Daraszkiewich do not attach much importance to hereditary taint. In fact, Christian states that those who have neurotic and vesanic ancestors can never become true dements.

On the other hand, Joffroy maintains that dementia præcox is essentially a hereditary disease. Morel thinks that alcoholism in parents is responsible for the malady. Clouston says that "the insanity of puberty is always a strongly hereditary insanity; it, in fact, never occurs except where there is a family tendency toward mental defect or toward some other of the neuroses." "My own observations on cases of well developed dementia præcox,' writes Jelliffe, "which I have been able to follow for many years and whose parents have been well known to me, have shown that three elements have been most emphatic in the ancestry, dementia præcox itself, alcohol, and abnormal personality or crankiness, if I may so express it.

The statistical data of the well known observers may be illustrated by the following table:

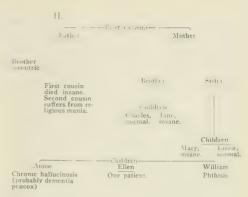

| may be mustrated by the following table. | | | |
|--|---|----|-----------|

In sixty-four per cent, of my own cases it was possible to demonstrate neuroses, psychoses, eccentricities, and alcoholism in patients' genealogical tree. The classification of the type heredity as well as the frequency of occurrence may be given in this outline:

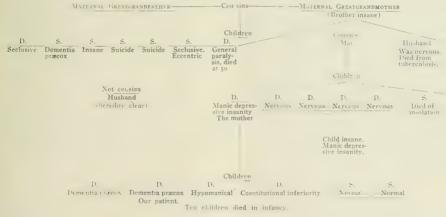

The following two interesting genealogical diagrams are of two patients who belong to this group of cases:

I. As far as could be traced the whole family inter-

ences to the development of morbid mentality is rather important. In the literature the subject is treated meagrely; only casual allusions are made to particular mental and nervous diseases, but are not mature for deductive purposes. Dexter, in his book on Weather Influences, states that "arrests for insanity are below the normal in prevalence during the colder months of the year, and above the normal for the warmer, though not the hottest months; are affected but slightly by different degrees of temperature, except by the very hottest, which produce a marked increase: are excessive for low and de-

Autointoxication.—Kraepelin suggests and the French believe that dementia præcox originates from an autointoxication process. Ingenious theories have been evolved which are plausible in books, but ridiculous in their practical applications. The disorders are ascribed to faulty hepatic metabolism, defective intestinal, and renal elimination, and to pathogenesis of the ductless glands. So far the biochemical investigations have rendered no valuable aid towards the solution of this problem. The labors of the chemist should be encouraged, but their results must contain thorough scientific worth before receiving our recognition.

Scasons.—The relation of meteorological influ-

ficient for high barometrical conditions are more prevalent for periods of low humidity than for high; are deficient for calms, with little effect from higher wind velocities; are slightly above the normal for 'fair' and considerably above for 'dry' days."

In the study of my patients, it was utterly impossible to determine the condition of the weather at the time of onset of the psychosis, but the relation of the season to the development of the disease was established with little difficulty.

The statistics are given in the following table:

Spring. Summer. Fall. Winter. Not known.

23 26 20 38 23

Age.-Beyond doubt age is an important predis-

posing factor in mental diseases. A great number "Psychoses and of cases occur in adolescence. neuroses," says Hall, "abound in early adolescent years more than at any period of life. This causes great emotional strain, which some have described as a kind of repressed insanity that is nevertheless normal at this period." "Out of 1,800 insane, Clouston found 230 between fourteen and twentyfive years of age; forty-nine between eighteen and twenty; 157 between twenty-one and twenty-five years of age. Fink reported that of 1,892 inmates of the Würzburg Hospital, 228 were twenty-nine, 12.15 per cent. males, and 11.5 per cent. females. Cullare found in France that 4.7 per cent. of all were between fourteen and twenty, and 8.8 per cent. between twenty and twenty-five.

Ziehen asserts that dementia hebephrenia is a disease peculiar to puberty, and in delayed periods it may occur from twenty-one to twenty-five, but never after twenty-five years of age. The same author, however, says that catatonia may become manifest in all ages. Sixty per cent. of Kraeplin's cases of dementia præcox occurred before twentyfive, and only five per cent. between forty and fiftyfive years of age. In Serieux's forty-six cases, the

ages ranged as follows:

| 1 | Age. | | | | | | | | | | | | | | | | | | | | | | | | N | umber. |
|----|------|-----|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|--------|
| 15 | to | 20. | | , | | , | | | | | , | | | | | | | | | | | ٠ | | | ٠ | 6 |
| 20 | to | 25. | | | | | | | | | | | | | | | | | | | | | | | | II |
| | | 30. | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 35. | | | | | | | | | | | | | | | | | | | | | | | | |
| | | 40. | | | | | | | | | | | | | | | | | | | | | | | | |

In Christian's 104 patients of dementia præcox, fifty-six were below the age of twenty and fortyeight above twenty. Most of Crocq's cases were between twenty-five and thirty-five; after thirty-five it gradually declined, and beyond forty-nine it was infrequent. Aschaffenberg found dementia præ-cox seventy-four per cent. in men and eighty per cent. in women till the age of twenty-five; the cases which developed in the fourth decennium were usually in concomitance with pregnancy and lacta-

Out of my 130 cases, it was found that ten were between twelve and sixteen years of age; ninetyeight between seventeen and thirty; seventeen between thirty-one and thirty-nine; five between forty-two and forty-eight years of age.

It is interesting to note that only in two cases the

mental alienation developed at puberty. Both of them showed psychotic traits, and in one heredity was demonstrated. In one of these patients, in addition to these factors, fright acted as an exciting

The following are complete records of three oldest and two youngest cases of dementia præcox:

CASE I.-Lena H. Admitted to this hospital on June 10, 1904.

Æt. seventeen. Russia (Hebrew); heredity; single. Family history: Paternal aunt was temporarily insane.

Paternal grandfather was subject to spells of melancholy. Paternal grand uncle was melancholy.

Personal history: Patient was born in Russia in 1887. During her intrauterine life mother sustained a fall, but apparently without ill effects. Labor was difficult, but not artificial resuscitation was necessary. From the age of six months to one year she was subject to convulsions.

She was quiet, seclusive, had no initiative, everything she did was in a mechanical way, and was not as lively as her sisters and brothers. Her education was only fair. She was poor in her studies and would exert great mental effort in order to keep up with the class.

Menstruation never appeared.

At the age of eleven she suffered from measles and pneumonia. Soon after the establishment of convalescence she became quiet, depressed, would remain alone, and manifested no interest in her environment. While on her journey to the United States she was inactive, and displayed placid indifference.

In this country she was sent to school, but she showed no efficiency in mental work, and was soon forced to aban-

don her studies.

At twelve she told her mother that she had peculiar thoughts, would often cry, was afraid to go out on the street, and at night she would scream out loudly, "Oh. Mama!"

She gradually declined mentally, and at about the age of fourteen she refused to dress herself, and would not eat for days, remained seated in one place, would speak to her-self, and frequently cried and called for her mother. She would wet and soil herself.

Since the age of fifteen she became practically mute. Shortly before admission to this hospital she became excited, disturbed, destructive, refused food, and was very She was sent to Bellevue, from where she was

admitted here on June 10, 1904

Upon admission to this hospital she was quiet, answered no questions, occasionally frowned, carried out no commands, and manifested no interest in her surroundings. On account of her marked inaccessibility, delusions, and hallucinations could not be demonstrated. Gavage was nec-Physical condition showed no marked pathological conditions. On the next day she gave expression to a peculiar jargon which could not be understood very well. Soon she commenced to to take food and her appetite was ravenous.

During her residence in this hospital her condition re-

mained without important changes

As a rule patient sat quietly all day long, chewed rags, at times saliva drooled from mouth, took no interest in what transpired about the ward, did not associate with her fellow patients, and was dressed and undressed by an attendant. At times laughed and smiled to herself without a tendant. At times laughed and smiled to herself without a recognized cause, was not spontaneously productive and answered no questions. Often she made grimaces and gestures. The visits of her parents produced no impression upon her. She had many spells of excitement. On one occasion she was talkative, cried, appeared apprehensive, tossed herself on the ground, and was much disturbed. When excitement subsided she was extremely timid, and frequently jumped up suddenly as if reacting to extremel citizent in the contract of external stimuli, but was inaccessible to examination. (We have only one record of such an episode-the others were accompanied by destructiveness and mild hyperactivity.)

CASE II Jussie P Admitted August 2, 1007. Et. sixteen; Russia; single.

Family history: Paternal uncle was eccentric and flighty.

Personal lustery: Patient was born sixteen years ago in the western part of Russia. During intrauterine life mother frequently menstruated and was weak. She was the fifth of seven children. She attended school and was considered a good student. She was always quiet, would brood over trifles, and at times would become nervous. Otherwise she was considered bright, cheerful, and pleasant.

She never menstruated.

In the spring of 1904 she was frightened by her aunt, who was regarded peculiar and mentally unbalanced. (This

aunt was not consanguineous, but by marriage.)

Ever since then it was noticed that she would shrug her shoulders, was afraid to go to her aunt, and in fact, feared the house in which the aunt lived. Frequently she would cry, and refused to go to school. At this time she commenced to react to hallucinations, and often remarked, "What does he want—he wants me to eat." During these hallucinatory episodes she would become irritable and excitable, destructive and assaultive. At this time she would go to her room and remain by herself. She thought she saw black cats and heard the voices of her dead relatives. At times she would take food to excess, and at other times she would eat very little. Occasionally she assumed an ag-gressive attitude toward her mother. Whenever she was sent on an errand or to school, she would run very fast, as if she were driven by some one.

Shortly before her admission to this hospital she became

much excited, manifested assaultive acts, screamed and shouted, and refused food. She was sent to Bellevue Hos-

pital in the latter part of September, 1904.

While there she was depressed, apprehensive, and reacted to hallucinations. She said: "Somebody is trying to kill me—I was afraid—talk about me—at night—I saw Christ in the woods to-night—I was afraid—in Russia is no Christ

-I saw Christ here.

When admitted here on September 28, 1904, physical examination showed some stigmata, slight eruption, and exaggerated knee jerks. Mentally, she was restless, appeared confused, suspicious and apprehensive. She was not very accessible to examination; only after much urging she answered but few questions. The following replies to answered but few questions. The tolking queries will illustrate her peculiar trend of thought:

"I don't

queries will illustrate her peculiar trend of thought:
"Why did they send you away from your home?" "I don't
know, I was crying." "What were you crying about?" "I
don't know." "Were you afraid?" (No answer). "Where
do you live?" "With my mother." "What street?" (She
jumps up nervously from her chair and shakes her head.
"What kind of a house is this?" "I don't know."

During her residence in this hospital she was irritable, timid, peevish, and would frequently cry or laugh in a childish fashion. Often she would make peculiar motions, and would pick her face aimlessly. She was not very

communicative.

In May, 1904, she became quieter, more composed, and fairly tractable. At the time of her parole (June 9, 1904) she was quiet, answered questions readily, appreciated that she was in a hospital, was anxious to return home, but exhibited no insight into her mental condition. However, she

was still nervous and mildly restless.

When returned home she was not considered well men-lly. She answered questions readily, and would assist with light work about the house. However, this lasted but a short time. She was not allowed to go on the street for fear of getting lost. For several days she would not eat, and then again her appetite was ravenous. At times she would become excited, and then she would suddenly say, "Why did he hit me? What do you want from me?" She often talked to herself in a loud tone of voice.

For the past year she grew gradually worse. She was restless, would run away, inclined to be destructive and

assaultive toward the members of her family

August 2, 1907, she was readmitted to this hospital.

Her mental condition remained practically unchanged. She was restless, uneasy, and fidgety in her behavior. She shrugged her shoulders, rubbed her face, raised her skirt, picked her nose, and made many bizarre motions with her hands. At times she emitted peculiar sounds which could not be distinguished. Quite often she laughed to her-self loudly. When questioned she did not seem to make any effort to comprehend the examiner and her answers were given in a haphazard manner, and accompanied by no affect. For instance:
How do you feel? "All right." Day? "The 8th."

Date? "Monday." Month? "Friday." Year? "58." (At another time gave "6.") Place? "68 street." Are you sick? "I don't know." What sickness? "No." How many fingers? "6." How many noses? "1." How many cheeks? "Nothing." How many tongues? "1." How many cheeks? "Nothing." How many feet? "6." How many teeth? "8." How many tongues? "50." How many papas? "6." How many mamas? "6." How many brothers? "6." She bestowed proper attention upon her person and also

She bestowed proper attention upon her person, and always appeared clean and tidy. At times would polish the

ways appeared clean and tidy. At times would polish the floor, but could not be engaged in an intellectual occupation.

CASE III.—Mary T. Admitted March 15, 1907. Æt. fifty-five; Russia (Hebrew), widowed.

Family history: Negative.

Personal history: Patient was fifty-five years of age, and was a native of the southern part of Russia. Nothing was known of her early infancy or childhood. At eighteen she married; gave high to six children; one of them died in married; gave birth to six children; one of them died in infancy. She immigrated to the United States in 1901. She was always irritable, frequently got excited, angry, and would tear her hair, inclined to be seclusive, and was also

considered very nervous.

The first evidences of mental alienation became manifest at the age of forty-eight (two years before her immigration to this country), when several unpleasant events occurred in the history of her life. At this time her husband died, her sister was dangerously ill and death was expected, and her son escaped to America on account of some financial complication, and she (the patient) was therefore arrested and put in prison. As a result of all that, patient became depressed, cried quite often, was not able to sleep, and said that her son was dead. When letters were received from him she did not believe they were written by him. She thought everyone was her enemy. She was coherent in speech and attended to her household properly. She was afraid to go to the United States because she thought that she and her children would be electrocuted.

On the steamboat she maintained a dejected attitude, cried quite often, and imagined that she would be thrown into the ocean. When she came to this country she thought she would be killed, but soon she was convinced that this idea was erroneous. However, she was not considered a normal woman. She was suspicious, frequently heard imaginary voices which called her vile names, and people wanted to harm her and the children. She had ideas of reference, said that people were following her and laughing at her, and misinterpreted sounds, actions, and behavior of men and women. Two years ago she took off her wig (which is contrary to her religion) because she imagined

people accused her of having a scalp disease.

In 1904 she conceived the idea that a certain pushcart peddler was killed, and his body put in the basement of the house where she lived. Her memory was not affected, and she was not restless at night. When she saw pictures she thought they alluded to her. The cartoons in the newspapers were supposed to represent her image. She would talk to herself and make motions with her hands. She attended to her household duties until eighteen months before admission to the hospital. A year ago she refused food for a week, remained in bed, was very quiet, was in constant fear of an ambulance which she imagined would call for her.

About eight months before her admission patient's condition grew worse. She burned papers and when asked to account for her peculiar acts, she used to say that in so doing she purified her person. At this time she gave expression to ideas of grandeur; stated that she was worth millions of dollars, and that all the houses belonged to her. When she was threatened with dispossession she laughed and said, "How could this be possible when I live in my own house?" Frequently she demanded that a demonstration should be made in her honor because she was a queen. Whenever money was mentioned to her she would say "fæces." She talked to herself, laughed, and smiled without apparent cause, and at times gesticulated. Shortly before her removal to Bellevue Hospital, she imagined that her vaults were stolen from her; she would go to her tenants and ask them to return her money. At this time she became much depressed, distubred, spent most of her time in crying, and could not sleep or eat. She was sent to Bellevue

Upon admission here physical examination showed:

Eruption on face; skin rough and pigmented; knee jerks

exaggerated; evidences of senile decay.

Mentally the patient was noisy, troublesome, attention could not be obtained, she moaned, frequently cried, and at times showed agitation. When an atempt was made to examine her, she became disturbed, cried loudly, appeared suspicious and apprehensive. She was perfectly inaccessi-

Her mental condition showed no important changes. may be described as followe: Quite frequently she shouted, cried, and screamed at the top of her voice. When she saw the ward physician, supervisor, or strangers, she became excited, stamped with er feet, spat in their faces, and gave expression to abusive speech, and at times manifested assaultive acts. As a rule her speech was very incoherent, showed a tendency toward verbigeration, used a peculiar jargon which could not be distinguished, and was particularly fond of obscene words and phrases. not accessible to examination, and when questioned she not accessiole to examination, and when questioned size said: "Don't touch me, I am a pure woman—you are not clean—you have in you a spirit and a devil," etc. She stated she had nineteen children. Her mood was variable; at times she was depressed and apprehensive. In her habits she was clean, and she bestowed proper attention upon her personal appearance. She slept well and did not manifest nocturnal restlessness.

CASE IV .- Mary H. Admitted June 15, 1907. Æt. forty-

six; Ireland; housewife.

Family history: Maternal cousin was insane. Father died from asthma; he indulged in alcoholic excesses. Husband suffered with syphilis; initial lesion appeared nineteen

Personal history: The informant had known patient for the past nineteen years. He married her eighteen years ago. She had five children; two died in childhood; had

one miscarriage.

She was always quiet, not talkative, seclusive, attended to her household duties properly, and was considered fairly intelligent. She had no education; could only write her own name. She would occasionally take a glass of beer and whiskey, but was never intoxicated. Menstruation was irregular; it would occur once in three months

Psychosis: August 5, 1906, her son stole \$200 from her, and suddenly disappeared. No trace could be found of him. Soon after this she commenced to worry, and would talk about her missing son, but at the same time she attended about her missing son, but at the same time she attended to her housework. One month later she would assume a sitting position all day long, would not do any work, and ofttimes would cry. Last November she said that she saw her name on the cars, and conductors were looking at her. She would say to her husband, "Here is my name in large letters—go and take it off—go to the car stables and report this matter." In April and May she would frequently become disturbed, would destroy things about the house, and would make an attempt for the window. For the past few months she had neglected her person, would not do her work, stated that she heard people call her vile names, and that she was watched by men. She said that she got a bad name and was accused of being an immoral woman.

bad name and was accused of being an immoral woman. On admission to the hospital patient was mentally quiet, depressed, spoke coherently, and complied readily. Asked if she felt sad she said, "Well, no, sir, I don't—I feel happy." (Looked depressed). Why so happy? "I didn't do anything wrong, and I don't feel unhappy." Have people talked about you? "I didn't hear them talking about me, but I see them looking at me." How long has this been going on? "I never used to go out much because I didn't want people looking at me so much for nothing." didn't want people looking at me so much for nothing; I noticed them long ago." You have been annoyed a good while? "The neighbors were the cause of it—they would not mind their own business." Did you ever find them out? "No, always kept at the back window, I never went to the front." She knew the day and month, called the place Blackwell's Island.

On the twentieth of June she was mute, tube fed, and wet and soiled the bed.

July 10th she answered questions in a low voice with little hesitation, said she perceived the odor of dead and human dirt. She admitted hearing voices in the left ear, and, as she put it, "It is preaching—rendering the doctrine of the Catholic faith-it comes from a saint and I hear it

On the fifth of August patient was morose, gloomy, gave On the fifth of August patient was morose, gloomy, gave sarcastic and pert replies, and was not very accessible to examination. When asked what place it was she replied, "The last place God made and He forgot to finish it." Are you sick? "Yes, I am." Have you any trouble? "Brain fever." Do you hear voices? "No, I speak to voices all the time." Why did you come here? "Why, I came here to look at the buildings—this is the nicest scenery here." When further questioned about coming here, she said, "I This is a peep show—I was brought here for a show.

While under further observation patient was quiet, seclusive, did not employ herself, and did not manifest great interest in her environment. She spoke slowly in a coherent strain, answered relevantly, and cooperated fairly well. She stated that about two weeks before coming here a man entered her womb and remained in her body; he was man entered her womb and remained in her body; he was in the chest, back, and everywhere; he was in her body because she was an angel; he told her to be happy and prayed for the people. He sang quite often and told her what to say. He spoke to everyone on religious matters. He said that everyone should be good and lead a good life. She heard him in the left ear. The clergyman lay always one neard nim in the lett ear. The clergyman lay always in her body; he did not eat or sleep; once she heard voices at night. She knew the day, gave the month incorrectly, and the year 167. This place was Blackwell's Island. She saw no insane women in the place. Her retention was poor. Memory for the remote past was fairly good, but for the immediate past was rather defective. Mood was that of indifference. that of indifference.

Physically, her knee jerks were somewhat brisk, pupils were responsive to light and accommodation, no perceptible

tremors, no defective speech.

On November 20, 1907, she died from strangulated hernia.

On November 20, 1907, she died from strangulated hernia. No autopsy was permitted.

Case V.—Ida D. Admitted on April 28, 1904. Æt. forty-three; United States; single.

Family history: Father, brother and sister, died from tuberculosis. Maternal uncle died insane; two maternal cousins are now mentally deranged. One uncle died from

apoplexy. Personal history: Patient was born in this country in 1861. She received a moderate education, and was a good musician. Menstruation accompanied by no abnormal

phenomena.

She was always sullen, seclusive, was not fond of amusements, and quick tempered. She indulged in no alcoholic beverages.

In the winter of 1904 she suffered from pneumonia; convalescence was protracted, and during this time her brother

was also sick with the same disease

In January of 1904 she commenced to worry about her brother's condition. She became quiet and depressed. After her brother's death the depression and unnatural quiet-ness became more pronounced. When she was spoken to she would stare vacantly, and answered no questions. condition grew gradually worse. At times she would throw articles at her mother and sister. She became resistive and extremely filthy in her habits. Her commitment was im-

Upon admission to the hospital physical examination showed no definite pathological lesions of the vital organs.

Mentally she was quiet, complied with requests readily, and made few spontaneous remarks, which were limited to the following: "Oh, those poor creatures—these poor creatures! What is the matter with them?" Her expression was sad. Her attention was difficult to obtain. She looked at the examiner in a perplexed manner. She appeared un-easy, and fidgety in her behavior. When asked for her name, she said: "My own name—(shook her head, rubbed name, she said: "My own name—(shook her head, rubbed her hair) that ain't right—well, my own name—I know my name—well, it is not right for those other people to go up—maybe I will tell you by and by." How old are you? "When I came here yesterday there was Mrs." What year is this? "Wait a minute." What month is this? Suddenly "This young woman." What day is this? "I say this is not right—this is not right."

On the next day she was strongly resistive, masturbated openly, talked in a disconnected strain, and was mildly distractable. She said, "Last night I picked up something-a

ring—the bishop—J. C.—Jesus Christ—I can read that—(looking at notes) in the Bishop's room—state room—May's eyes—they walked in—went on chair—in state room—and covering up the little children—them children out there—the priest—coming on the boat—(priest was in the ward) she was not there." When questioned regarding hallucinations, she said, "Sometimes I hear delusions." What do you mean? "Cursing, calling me names—wh—son of a b—." Where do they come from? "Intemperance caused it—I guess it always sounds in my ears—sometimes loud—I hear them at night the most." Do you answer them? "Yes, I tell them to go to hell."

them? "Yes, I tell them to go to hell."

April 30, 1904. Patient showed great variability in attention; at one time answered questions readily, and then again made irrelevant and peculiar replies. For instance: Who brought you here? "I ain't a Guinea." Why do you say that? "Ain't they calling me a Guinea around here?" How did you get here? "No, I came on the boat, train and free." What do you mean by fire? "Burning the yellow house down." Who brought you here? "My mother used to come here and we descended from the soldiers." What nouse is this? "Oh, my head is muddled up."

May 6, 1904. Patient gave some data about her personal history. She stated that her age was forty-five and that she was born in 1859; went to school from eight to sixteen; gave the month, year and date correctly; the place was either M. S. H. or Bellevue Hospital. Her answers to some questions were irrelevant and bizarre. Why did you

May 6, 1904. Patient gave some data about her personal history. She stated that her age was forty-five and that she was born in 1859; went to school from eight to sixteen; gave the month, year and date correctly; the place was either M. S. H. or Bellevue Hospital. Her answers to some questions were irrelevant and bizarre. Why did you come here? "They put us out of the house because we did not pay our rent and they sent us here." Why did you go to Bellevue Hospital? "They took me to see my brother, who was sick, and they set a trap and got me into the station house, and then took me to Bellevue; then my head got muddled."

Since May 27, 1904, patient refused to answer questions, offered no spontaneous remarks, and was practically inaccessible mentally. She was obstinate, resistive, masturbated in a shameless manner, and at times reacted to hallucinations. On July 11th she became wildly excited, and assaulted the nurses. This was only of short duration. For the past three years patient was quieter, at times

For the past three years patient was quieter, at times masturbated openly, and was obstinate and resistive. She assumed a sitting posture, head bowed, and hands folded. Often she muttered to herself in a low tone of voice. At times laughed and smiled to herself in a childish fashion. She answered no questions and complied with no requests. The visits of her relatives and friends made no impression upon her. She showed muscular rigidity in both arms, and neck. She reacted promptly to pin pricks. She required constant attention from attendants; it was necessary to dress and undress her. She wet and soiled herself.

Nationality.—The rate of frequency of mental alienation in a particular nationality cannot be definitely estimated. It is stated that insanity bears a direct ratio to a nation as the latter to civilization. The fact that modern civilization is a contributing factor to neuroses and psychoses cannot be questioned. The distinguished American sociologist, Professor Giddings, says: "Degeneration manifests itself in the protean forms of suicide, insanity, crime, and vice, which most abound in the highest civilizations, where the tension of life is extreme, and in those places from which civilization has ebbed and from which population has been drained, leaving a discouraged remnant to struggle against deteriorating conditions." . . . "The statistics of insanity are imperfect, but there is no doubt that insanity has greatly increased within a generation and is still increasing, and that it is most prevalent where life is intense or hard."

Our information regarding this interesting subject must depend upon statistical documents. For the fiscal years beginning October 1, 1906, and ending September 30, 1907, 834 women were admitted to the west division of Manhattan State Hospital. The majority of the patients came from the United

States, Ireland, Germany, Russia, and Austria, as this table will show:

| Nation. | No. |
|---------------------|-----|
| Austria | 52 |
| Bohemia | 3 |
| Belgium | 2 |
| British possessions | 2 |

In my own cases, forty-eight were Americans, twenty-seven Russians, seventeen Irish, seventeen Austrians, eleven Germans, three Italians, three Hungarians, one Roumanian, one Cuban, one French, and one Finnish.

It is extremely interesting to note that the Jew shows a great predilection to neuroses and psychoses. Of 834 women admitted to Manhattan State Hospital for the past year, 188 were of the Jewish faith—thus making about 22.5 per cent. In my 130 cases, fifty-three were Jews.

Kraepelin is of the opinion that consanguineous marriages among the Jews are responsible for the frequency of insanity. Emil Meyer maintains that due to force of circumstances the Jew was compelled to lead a seclusive life, and, moreover, his/occupations are of such a nature which require no bodily activity. It must also be borne in mind that the Jew lacks an important phase in his education -physical culture. He bestows too much attention upon the mind and completely neglects his body. One must not overlook a striking fact in the history of the Jews. Ever since time immemorial this race was the world's stepchild. They had many and many a cruel stepmother, who treated them without pity or shame. Hence, by reason of this long and continuous torture, abominable abuses, and contemptible treatment, the Jew acquired a neurasthenoid constitution and a psychopathic predisposition.

Psychotic Traits.—"On one side," says Kraepelin, "many observations speak in favor of a disease process which can develop long before that shown in our diagram. Especially it appears to me that the fact is worthy of being emphasized that in about twenty per cent. of our cases certain peculiarities in early childhood were quite often noticed long before the symptoms of dementia præcox fully developed. They were seen in connection with mild phases of the disease—seclusiveness, fear of people.

capriciousness, over religiousness, unruliness, irritability, affectation, and lack of moral control. Not infrequently well defined mental enfeeblement is present upon which a new disease is engrafted. As it appears to me, herein lies the solution, that they are deviations from the normal in the youth and early adolescent life, and they are succeeding phases of the same disease which later become manifested as dementia præcox." And August Hoche also expresses similar ideas—"that a number of cases of juvenile dementia were before the onset of the disease marked by nervous and mental stigmata; from the anamneses it was learned that patients often suffered from enuresis, pavor nocturnus, somnambulism, irritability during the menstrual epochs, etc., or they were seclusive or wilful; in a small number of cases they were weak mentally." Adolf Meyer states that ætiologically the constitutional makeup counts for a great deal, but not in the vague sense of heredity and degeneracy merely: "In cases of dementia præcox we find over and over an account of frequently perfectly exemplary childhood, but a gradual change in the period of emancipation. Close investigation shows, however, often that the exemplary child was exemplary under a rather inadequate ideal, an example of goodness and meekness rather than of strength and determination, with a tendency to keep to the good in order to avoid fights and struggles. Later religious interest may become very vivid, but also largely in form; a certain disconnection of thought, unaccountable whims, make their appearance, and deficient control in matters of ethics and judgment; at home irritability shows itself often wrapped up in moralizing about the easy going life of brothers and sisters; sensitiveness to allusions to pleasures, health, etc., drive the patient into seculsion. Headaches, freaky appetite, general malaise, hypochondriacal complaints about the heart, etc., unsteadiness of occupation and inefficiency, day dreaming, and utterly immature philosophizing, and, above all, loss of directive energy and initiative without obvious cause, such as well founded preoccupations, except the inefficient application to actuality. All these traits may be transient, but are usually not mere neurasthenia, but the beginning of a deterioration, more and more marked by indifference in the emotional life and ambitions, and a peculiar fragmentary type of attention, with all the transitions to the apathetic state of terminal dementia."

In about sixty-eight per cent. of my cases it was conclusively demonstrated that the patients presented psychotic traits during their childhood and adolescent life. These were: Seclusiveness; timidity; fear of being alone; unsociability; not fond of amusements; cherishing solitude and shunning company; unnatural piety; sanguine temperament; irribability; easily angered and excited; brooding over trifles; crankiness; capriciousness; egotism; haughtiness; sensitiveness; vindictiveness; general backwardness and absent mindedness; lack of initiative; childish laughter; inclination to obstinacy and indifference; inability to learn a trade.

One of my patients in her normal days had a habit of shaking her head from side to side. Another would cry loudly while doing her lessons. Another was always dreamy, had no initiative to do

anything, could not learn a trade, and inclined to be seculsive. Another was extremely shy and unsocial, was not fond of playing, would conceal herself from strangers, was irritable, absent minded, and obstinate. Another was afraid of music, would make peculiar grimaces and gestures, was easily angered, and could not get along with children.

It is worthy of note that in sixty-seven per cent. of these patients vesanic or neurotic heredity was

determined.

Education.—Faulty systems of education, as well as mental surmenage, are contributory factors to all forms of adolescent insanity. Jelliffe asserts that "school work is not the only cause of fatigue by any means, but it plays a rôle in the genesis of the neurasthenoid background which is so prominent a feature in many of the predementia præcox signs, and one cannot fail to be impressed by the unnatural fatiguability of these individuals. . . . Such good observers as Emminghaus, Ziehen, Eulenberg, Pick, L. Strumpell, Kahlbaum, Hecker, Christian, Wille, Uffelmann, Biswanger, Baginsky, not to mention scores of others of equal prominence, all describe well marked neurasthenic development in the child, and young adult, and ascribe them to the overburdening of school life."

In one of my patients, mental surmenage was regarded as an important factor in the causation of her mental breakdown. She was a young woman of eighteen, attended New York Normal College, and was apparently bright in all studies save mathematics. She had to work very hard in order to keep up with the class. She at last failed in this subject at her final examination. The over exertion of mental effort associating with the worry over failure in examination caused her mental breakdown. She could have been saved if the pedagogues would not have attempted to force upon her a subject for which she showed no inclination.

Thirteen of my patients were poor in their studies; twelve were exceptionally bright, one, who was of Irish extraction, carried honors in German, and another graduated from school with a medal; seventy-two patients received a fair education; forty-one graduated from a common school, three attended high school or normal college; fourteen were illiterate.

ere illiterate.
(To be concluded.)

PERITONITIS DUE TO APPENDICITIS.

With Special Reserves to Diffuse Suppositive Peritonitis.*

BY FRANZ TOREK, A. M., M. D.,

Attending Surgeon to the German Hospital and the New York Skin and Cancer Hospital; Adjunct Professor of Sungay in the New York Postgraduate Medical School.

If the appendix perforates in consequence of inflammation and the opening has not been closed by adhesions, there results a more or less extensive infection of the peritoneal cavity. This infection may spread in a short time over a great part of the peritonæum, or a circumscribed abscess may form. This abscess, however, may later on burst through its walls and invade almost the entire peritoneal cavity.

*Read before the German Medical Society of the Co. 31 New York, November 2, 1908

Such an invasion of the peritoneal cavity was formerly called "general peritonitis," but as it occurs very rarely that the entire peritonaum is involved, that name has been abandoned and the term "diffuse suppurative peritonitis" has been adopted. To describe the extent to which the pus or purulent serum has spread, the following terms are employed: A suppurative process that is walled off from the rest of the peritoneal cavity is designated simply as an "abscess" or as "circumscribed peritonitis"; an extension over the greater part of the peritoneal cavity is called "diffuse peritonitis"; while those processes in which the purulent serum is not walled off, but free, which, however, have as vet extended only moderately far, are described as "progressive or spreading peritonitis." The term "diffuse suppurative peritonitis" therefore should be employed only in those cases in which the pus has extended well over to the left side of the abdomen. Unfortunately these terms are, even at the present time, not always strictly adhered to in reports upon cases, a fault which often causes the reader to receive entirely erroneous impressions.

It is true the exudation of serum and leucocytes on the part of the peritonæum is, as everywhere in the body, a salutary process which has for its object the warfare against the inroads of the bacteria. But, on the other hand, an extension of the purulent serum implies also the spreading of the poisonous material, and experience shows that in diffuse suppurative peritonitis the struggle, as a rule, terminates in favor of the bacteria, as the disease almost invariably ends fatally without surgical treatment.

Surgical treatment has for its object the removal of the appendix and of the pus. In the case of abscesses some hold that the removal and drainage of the pus will suffice; but if this plan is followed, the appendix should be removed later to insure against recurrence. I always remove it at the time of operating on the abscess, unless strong counterindications forbid. In progressive and diffuse peritonitis all agree that the appendix should be taken out at once.

In all cases of spreading peritonitis and in many cases of abscess the right rectus incision will give good access. Some abscesses are better attacked through a more lateral incision, in which cases the opening of the general peritoneal cavity can usually be avoided. The pus is removed by mopping, not by irrigation, and the abscess cavity is drained.

In spreading peritonitis-that is, in cases where the pus is free, not confined by adhesions, but as yet diffused over a teritory of limited extent—the pus is also removed by mopping, not by irrigating. By flushing one would incur the risk of spreading the pus to parts of the peritonæum which had not been involved. Drainage in these cases is not necessary, unless it is impossible to close the stump of the appendix properly, as may happen, for instance, if gangrene extends well up to the cæcum or even into it.

Now we come to the most important cases, those of diffuse suppurative peritonitis. This form has always put to a test the best efforts of the surgeon. The method of treatment has gone through the gamut from simple incision and drainage up to the employment of numerous incisions in different parts of the abdomen with copious gauze packing, without, however, showing any improvement in the results, recovery being rare. In fact, it was found by animal experiments that extensive gauze packing in the peritoneal cavity was distinctly harmful. This was, therefore, given up, and a single incision in the right lower quadrant was again used, special weight being attached to the importance of washing out the peritoneal cavity. This was done with the aid of a long metal tube introduced through the wound. Then a small drain was introduced. The success appeared to be quite satisfactory, and several surgeons pointed with pride to the fact that it had been possible to save fifty to sixty per cent, of the cases by this method combined with Fowler's position.

Fowler's position, a posture in which the pelvis is low, while the back and head are raised, was employed for the following reason: It had been shown experimentally that colored fluids introduced into the peritonæum were absorbed most slowly in the pelvis and most rapidly in the diaphragmatic portion. In view of this observation the fact that those cases of appendicular inflammation with diffuse suppurative peritonitis, in which the pus had found its way to the diaphragmatic region, were particularly serious ones, was construed to signify that the more active absorption of the pus by the diaphragmatic peritonæum was responsible for the sepsis. reason Fowler introduced his posture, so that the pus should flow away from the diaphragm toward the

pelvis, which he drained.

This argument sounds quite logical, but on closer scrutiny is found to be faulty in the following points: In the first place, those experiments for studying the absorption of fluids in different parts of the abdominal cavity were made with non-irritating fluids and do not permit us to draw any conclusion as to the behavior of pus. It is safe to assume that the stomata in the diaphragmatic peritonæum will close promptly when irritated by a septic fluid. In the second place, it must be considered that the cases in which pus from a perforated appendix has extended to the diaphragm, are serious ones for the very reason that the suppuration must be very extensive in order to reach that part. The more the pus spreads, the higher it will ascend and the more severe will be the peritonitis. The presence of pus in the diaphragmatic portion, therefore, characterizes the cases as serious simply because it signifies a wide extension of the peritonitis. In a similar manner a peritoneal collection of pus having its origin from an ulcer of the stomach would be of far more sinister significance if it extended down into the pelvis than if it remained confined to the region of the ulcer. In the third place, it is a mistake to assume that pus which may remain in the peritonæum after lavage will flow to the deepest point in the same manner as ascitic fluid does. Accumulations of pus that were not evacuated by the lavage were certainly in part shut off by adhesions and cannot flow down, while. in the case of freshly forming pus, the loops of intestine have ample time to obstruct its descent.

My own method consists in making a large median incision, which in most cases extends to a couple of inches above the navel. The appendix is rapidly exposed and tied off. The pus which pours out on opening the peritonæum and on searching for the appendix is at once rinsed off with salt water, so that the removal of the appendix may be done in a terri-

tory not too much soiled. Then follows the careful cleansing of the peritoneal cavity by pouring saline solution from bottles or pitchers. This is done systematically, taking up one region after another, for instance, first the region of the appendix, then the pelvis, then the left lower part of the abdomen, finally the parts higher up. During these manipulations the intestines must be treated as tenderly as possible. The wound then is closed completely with through and through silk sutures, no drainage being employed, unless it has been impossible to close the stump of the appendix, in which case a drain is introduced down to the stump through a separate small lateral incision. Furthermore, I do not employ Fowler's posture and avoid inducing peristalsis during the first five days.

This mere outline of my method must suffice, as I have already described it fully, citing eighteen histories (Medical Record, December I, 1906). Of those eighteen patients I succeeded in saving fifteen, or 83½ per cent., a figure which up to the present time has not been approximated by other methods. I have now completed a second series of eighteen cases, again with three deaths, so that the percentage of recoveries has remained the same. That my cases were not selected will at once be plain through the fact that I have refused to operate only in a single case, that of a private patient who was brought to the hospital in a moribund condition and died a few hours after her admission.

The following points in my method may require some explanation: 1, The large median incision; 2,

cleansing by irrigation; 3, closure without drainage. By the large median incision we gain the best access to all parts of the peritoneal cavity and are better able to cleanse it than by a small incision at some other site. I have repeatedly evacuated collections of pus remote from the original focus, for instance, in the left upper quadrant, and already walled in by fresh adhesions. Such collections would not have been emptied if a small incision and a tube had been used for irrigating. The shock of the operation is not increased by the greater length of the incision. The numerous incisions formerly used and again abandoned did harm not owing to the extensive cutting, but owing to the excessive use of gauze packing for drainage. The unavoidable handling of the intestines, furthermore, can be done much more gently through the large incision than through one giving insufficient access-and gentleness in handling the peritonæum is an absolute condition for

The necessity of gentleness in handling also explains the second point, cleansing by irrigating. In no other way can the cleansing of the peritonæum be done so gently as by irrigating. The counter indication against flushing, which I mentioned in speaking of progressive peritonitis, namely, the danger of spreading the pus by flushing, does not exist in the diffuse cases, for in these the pus is already widely spread.

The third point, the closure of the abdominal cavity without drainage, rests upon the fact that the peritonæum, after it has been washed clean, is well able to cope with what little infectious material may yet be left. Furthermore, it is impossible to drain the peritoneal cavity, as may be seen from what I

said in reference to Fowler's position. Even drainage at five or six places would not only fail to fulfill its purpose, but would do harm, as experience has shown. In all my cases I have drained only twice, when the point of origin of the appendix could not be properly closed owing to extension of the gangrene to the cæcum. This was done by the introduction of a strip of gauze through a separate lateral opening. The indication for drainage in those cases was not the presence of diffuse peritonitis, but the expected escape of fæces.

The last word on diffuse suppurative peritonitis has surely not been spoken, but I hope that it has been my good fortune to add a mite to our knowl-

edge in this chapter.

59 East Sixtieth Street.

CHOLERA AND COMMERCE.*

By W. T. JENKINS, M. D., New York,

Former Health Officer of the Port of New York; Port Officer of the Anchor Steamship Company; Medical Director, Merchant Marine Hospital Service; Sanitary Engineer, New York Board of Health, etc.

I appreciate the honor of contributing to this "symposium" on cholera. The breadth of my subject is apparent, as also the difficulty of treating it adequately in the time to which I must confine myself.

I must deal chiefly with the interference of both commerce and the liberty of passengers caused by regulations to prevent the advance of cholera, although they have been of value in stimulating scientific research and in giving rise to international conferences and also many national commissions.

The results of these councils have been far reaching, as, for instance, the discovery of the spirillum of cholera, by Robert Koch, the reduction to concrete form of our knowledge of this disease, and the revolutionizing of the methods of quarantine.

Interesting and important facts are: The place of departure of the cholera is India; its path on land corresponds to that of travel and traffic. Its transmaritime advent, of course, has corresponded with the track of commerce, and its North American visits have been in cycles of about sixteen years.

The last outbreak in America was in 1873, an interim outbreak, the explanation of which may be found probably in the arrival of ships at New Orleans, when the epidemic entered on vessels from ports widely scattered all over the globe.

Doubtless on account of efficient inspection, no cholera appeared at any port in the United States in 1882, but in 1887 two French steamers arrived at Quarantine at New York with cholera aboard, but owing to prompt isolation and detention the disease did not get beyond Quarantine.

It was this appearance of cholera that caused the Academy of Medicine to appoint a committee which, at the request of the mayor, investigated the conditions of the port and made recommendations for such improvements as would bring the quarantine equipment up to the highest standard of modern scientific and medical knowledge. The result of its work was the plant which I received from my predecessor

"Read at a meeting of the Medical Association of the Greater City of New York, November 16, 1908.

in February, 1892. The next appearance of cholera, which was in August and September, 1892, was somewhat more formidable than the preceding one. It came from Hamburg during my first year's service as health officer, and its peculiarities are of sufficient interest to permit special mention, but before dwelling on its characteristics I wish to remark that it is instructive to note the following: The sixteen year period has begun to be modified by the increased volume and diversity of commerce. It will also become apparent that this importation was confined to the lower bay of New York harbor. On February 2d of this year (1892) I entered upon the duties of health officer. On the 30th of the previous month the steamship Massilia had cleared Quarantine after medical inspection. On the 11th of February the board of health reported the discovery of fifteen cases of typhus among the immigrants landed from this steamer. These were Russian Hebrews who, in accordance with the provision of the Baron Hirsch fund, intended to seek refuge in Palestine, but were denied passage through Turkish territory, and therefore took passage for America. This outbreak put the health officer on the alert. I notified all steamship companies of the necessity of detention, inspection, and disinfection of baggage at the ports of embarkation, and it is due to this watchfulness that seven months later an epidemic of cholera was prevented. On August 19th, from the daily telegraphic dispatches from which we had been studying the march of cholera through Eurasian inland towns, I predicted its outbreak in Hamburg; and, in accordance with my conviction, telegraphed the Secretary of State: "Please inform me if you have any information of cholera in Germany," to which I received the reply on the same day that he had none, but four days later I received the following telegram from the department in Washington: "Cholera officially reported in Hamburg." A few hours later a second message came, reading: "Following from consul at Hamburg: 'Health officer states officially Asiatic cholera in Hamburg. Have stopped bill of health.' While in full confirmation of what I had felt must

have been the case, I received on August 25th, two days later than the previous two telegrams, the following: "Our consul at Hamburg cables this morning: 'Hamburg authorities admit to-day Asiatic cholera; has been in Hamburg since the 18th. . . Cable if and how long quarantine will be imposed." I immediately issued proper regulations and telegraphed the same to the Secretary of State, and these were promptly sent to consuls abroad. results of these regulations (which, by the way, are still in force) appear in my report to the legislature in which I say: " . . . It is a matter of gratification that, although persons who brought cholera to Hamburg were passing through that and other ports constantly on their way to the United States, the continuation, throughout the entire period of this epidemic in Russia, of the consular hygienic measures contributed in no small measure to prevention of disease at this port. In addition to these preventive measures, means for bacteriological diagnosis and a complete hospital equipment were provided at this port. One serious difficulty was en-

countered.'

While previous provisions made it possible to deal with a limited steerage with infection, no provisions had been made to limit the freedom of cabin passengers, and in addition to this, and of greater moment, absolutely no provision was made to shelter or otherwise care for infected or suspicious cabin passengers. What made it more difficult was the fact that the committee of the Academy of Medicine in 1887 had failed to incorporate in its report any recommendation for such an emergency as the disposition of cabin passengers, an omission which was probably excusable, because previously cholera had not existed in the cabin.

During the period from August 31st to September 15th six ships with cholera arrived, two of which carried cabin passengers, and in the cabin of each suspicious deaths had occurred.1 The total number of cases admitted to Swinburne Island was seventytwo, and the percentage of death as stated by Byron² and Wilcox was only eleven. This excellent showing was due in large part to the treatment of Dr: Judson Daland, clinical instructor in the University of Pennsylvania, who was in charge. This consisted in a minute and painstaking medication and surgical

procedure, the latter predominating:

Treatment.—In the premonitory diarrhoea, if there was no collapse, the first step was to clear the bowels, which was done by the administration of 10 grains of calomel by the mouth, and this repeated every hour until three doses were taken or thorough evacuation secured. Afterward one half grain was administered every two hours. Stimulants were used as required, preferably brandy, generally administered hypodermically. In the stage of asphyxia the stomach and bowels were thoroughly washed out. For the stomach the Fancher tube was used for the purpose of introducing a 1 in 1,000 solution of hydrochloric acid. The procedure was repeated every two hours. The intestine was washed out with a two per cent. aqueous solution of tannic acid, half a gallon being used at a time at a temperature of 108.9° F., and repeated every two hours. A long (two feet) rectal tube was employed, the patient lying upon his back, and gentle massage was made if there was any difficulty of passage of fluid beyond the ileocæcal valve.

The purpose of this procedure was: I, To wash out the intestine; 2, to precipitate the ptomaines; and, 3, to warm the body. After each injection the bodily temperature rose from one to three degrees F.

When the pulse began to disappear and respiration became shallow, then hypodermoclysis was resorted to. The solution employed was sodium chloride, 3 parts; brandy, 10 parts; to 1,000 parts of sterilized water kept at a temperature of 104° F. One quart was used for an adult, and it was injected into the flanks at about the eighth rib, and was repeated every second to fifth hour, according to the necessities of the case. The largest amount used in one patient was eleven quarts. In several cases inhalations of oxygen at the rate of a gallon every hour, watching the heart, were resorted to. No nourishment was administered while vomiting persisted. At

Scholera, 1892, in New York. American bournal of the Medical Sciences, ev. p. 62.

other times peptonized beef juice, champagne, and milk with carbonated water—three parts of the former to one of the latter—were employed. The distressing cramps were avoided in all but two cases by placing the patients in a warm atmosphere, in their beds, near the steam radiators, and building a tent over them, so that they would be in a current of hot air. During convalescence a simple and nourishing diet was instituted.

It is of more than passing interest to contrast with this showing the reputed cases of cholera on the Island of Manhattan, where there were said to have been eleven, in two of which the nature of the disease was not determined, making in all nine cases of cholera with nine deaths. It is therefore evident that in this epidemic the cholera patients in the city showed, the largest death rate in the cholera records. It must also be noted that not one of these cases could be traced to any infected ship, either in or out of quarantine.

During the cholera epidemic there were inspected and passed with but slight detention at Quarantine from August 31 to October 14, 1902, crews, 34.612; first cabin passengers, 17.330; second cabin passengers, 13.050; steerage, 15.081—a total of 89.073, and although these ships passed near the quarantined fleet, not one case subsequently devel-

Of those who contributed for the supply of these unusual necessities, namely, detention and suitable care of cabin passengers, among whom there had been suspicious illness, Mr. J. P. Morgan, as famous for his charity as he is noted for his financial ability, is deserving of first mention. This philanthropist furnished the steamer *Stonington* of the Fall River Line. The navy lent the recruiting ship New Hampshire, and through the courtesy of the Secretary of the Treasury the use of Camp Low

was tendered, should I desire it.

What, however, was of greatest service was the purchase by Governor Flower, upon my recomendation, of Fire Island, including the Surf Hotel. Also worthy of notice was the action of Mayor Hugh J. Grant and President of the Police Commissioners, J. J. Martin, who at my request adequately policed the quarantine fleet by tugs manned by courageous volunteers of the regular police force. Shortly after, from my knowledge of the situation abroad and here, I was able to announce the arrival of the last cholera ship and on the fifteenth of October to publish the defeat of the cholera and the raising of quarantine.

In the year 1903 events notable in the history of quarantine occurred. Eminent professional and business men, following out an induction warranted by the previous history of epidemics, had concluded that an epidemic in 1803 was certain, and these views were spread abroad and accentuated in the public prints. In harmony with this view of the case, a bill had been introduced in Congress to grant additional powers to the United States Marine Hospital Service. This bill was opposed by me until I had the assurance that I should not be interfered with, but

should receive the cooperation of all concerned. This assurance I soon received. Any opposition on the part of the transatlantic transportation companies was not to be expected, even if cooperation was prompted by no higher motive than the saving of the expense of detention of passengers, the diminution of commerce, and the establishment of a bad reputation. Germany especially could be depended on for aid, since she had had the good fortune that one of her sons discovered the Spirillum choleræ, and now sought to maintain her reputation, by instituting and furthering scientific hygienic measures.

However, in order to insure absolute safety, special arrangements were made with one of the great transatlantic lines most deeply interested. And in conformity thereto I sent Dr. George W. Nash to Hamburg, to inspect the lodgings of emigrants, to supervise ship sanitation, and to certify to the general hygienic conditions. Very soon after his arrival Dr. Rosenau, of the United States Marine Hospital Service, also was ordered to Hamburg, where he remained until relieved by Dr. J. H. White. Dr. Nash and Dr. White worked harmoniously with our consul, with the result that no ship from Hamburg brought cholera to New York during this year, although there was a limited epidemic in Hamburg, which had been occasioned by the distribution of contaminated water from the Elbe. It was from this epidemic that a stoker of one of the express passenger steamers en route to America came down with cholera and was promptly put ashore at Cuxhaven. Dr. Nash, by request of the steamship company, boarded the ship at Southampton and accompanied her to this port. Professor Dunbar, of the Hygienic Institute of Hamburg, within a few hours after the patient was landed, demonstrated the presence of the cholera spirillum. Upon the ship's arrival at New York, though a demand was made upon me to order her detention at Ouarantine, since Dr. Nash reported all on board well and she had been out more than five days without illness and all precautions had been observed, I cleared the vessel without detention. Notwithstanding alarm was caused in certain circles, no cholera occurred, and the following valuable lesson was impressed upon the minds of all, that if proper cooperation could be had abroad, at sea, and in port: 1, It knowledge of the hygienic condition of snip and passengers before sailing, at sea, and upon her arrival is assured; and, 2, if on the arrival of the ship all persons aboard are well, there is absolutely no danger of introducing cholera into the country and therefore no reason for detention.

It may be said here that German ports have the most satisfactory arrangements for emigrants on shore, specially illustrated by the Auswandererhallen (Emigrant Hotel), of the Hamburg-American Line, at Veddel, Hamburg.

^{*}Dr. Reynold W. Wilcox. Ibid., pp. 61 and 62.

*See statement to this effect. American lournal of the Medical
conserve, pp. 65 and 69, article by Herman M. Bags, M. D.
Reynold W. Wilcox. Epidemic Cholean in the Port of New
York American Learnal of the Wilcox. Settled Sciences, October, 1893.

This hotel consists of two score neat buildings, covering an area of about fourteen acres. It has its Ifwish as well as its Christian guartee, and provision is made for supplying hashes tood to the Jews. The different races, as well as the two sexes and those of different ages, are housed separately. A water system; a sewerage system in which the sewage is disinfected in the most approved manner before it is disposed of; an electric light system; a large bath house provided with showers and tube placed in individual com-

Italy was specially to be feared in this year. I therefore sent Dr. Judson Daland to Naples, where cholera was epidemic, and he had surveillance of the ports of Italy and the Levant. On August 3d the steamship Karmania arrived, having had deaths on the voyage (she was a freight steamer on which steerage accommodation had been improvised). The causes of death, which were said to be various, included gastroenteritis. One case developed in port and the microscopical examination revealed the Spirillum choleræ. Immediately I requested the editors of all the papers to meet me at the mayor's office and laid before them all the facts, at the same time making the request in the interest of commerce and business generally, that no alarming or unnecessarv statements be published, while I would keep them informed by bulletin issued twice a day of the exact situation. As to the passengers, all were landed at Hoffman Island, divided into groups, and placed under the supervision of medical and sanitary police, while careful bathing and thorough disinfection were insisted on. Among these persons twentyone cases of cholera developed, all of which were transferred to Swinburne Island for treatment, which consisted of the method employed in 1892, and only four deaths resulted. The effect of the regulations established by the Department of the Port of New York for governing emigrants abroad, in 1892, were continued with the most evident good results. For instance, three vessels sailed from Naples when cholera was epidemic here, but only after the passengers had been detained in accordance with these regulations. All these arrived at New York without illness aboard, passed Quarantine without detention, and among the passengers no cholera developed

Contrary to this state, during the same season four vessels with the same class of passengers with similar place of origin, in many cases with the identical water and food supply, the same as on the vessels for the United States, left for South America. All, however, were turned back by the authorities and returned to Naples, the vessels having had respectively fifty, ninety, eighty-four, and two hundred and thirty deaths from cholera during the voyage. This is introduced simply to illustrate the ease

with which cholera may be controlled when proper regulations are instituted and carried out, such as were established by me in 1892, and failure to do so cannot but be fatal. The duty of handling these diseases at home rests

upon the local health officers of the port, but the rapid advance and discoveries in these diseases is fast reducing the health officer's work to mere inspection. Of the ports of the United States and its dependencies, all except New York, Boston, Philadelphia, and Baltimore are under the management of the Public Health and Marine Hospital Service. The port of New York is greater by far than all the others combined, having probably eighty per cent. of immigration, ninety per cent. of cabin travel, seventyeight per cent. of imports and tonnage, of the ves-

sels sailing under foreign flags.

The Public Health and Marine Service has, in addition to the functions for which it was established, the added duties of the examination of imigrants and of all the diseases, including mental deficiencies, in respect to which the emigration laws apply. This makes it necessary for the service to employ many private and public hospitals, which involve large expense, and this expense has to be borne by the steamship companies. This is a charge upon them which I believe is unwarranted, but if it has any ground for existence it is unjust for two reasons, viz.: 1. The charges are grossly excessive; and, 2, while the steamship companies are the chief parties interested, they are denied the right to be a party to the making of the terms, and what makes the situation the more paradoxical is that at the time when the United States Marine Hospital Service was pleading for a national quarantine, the statement was made that it would be less expensive than any local quarantine. Of all these charges the steamship companies should be relieved, especially because the head tax has recently been doubled.

Let me say here that I do not wish anything in this statement to be interpreted as an adverse criticism upon the United States Public Health and Marine Hospital Service, which has rendered and is offering to-day a service which is the nearest approach to a national health supervision and bureau of national and international sanitary information and investigation that has yet existed, but is sadly hampered by the limitation of its personnel, particularly so in the port of New York.

In conclusion, let me say that in thus considering my theme, the relation between cholera (epidemic) and commerce, I feel that the information gained at the port of New York, as I have just had the privilege of relating to you, has been of the utmost importance, not only to the welfare of the country at large, but especially to this port of entry, the volume of whose commerce annually is in the aggregate such that in 1908 \$191,000,000 was paid in duties, or sixty-six per cent., compared with the rest of the re-

maining ports of \$90,000,000.

No period in the history of our land is more representative in this respect than that which I have analyzed this evening and during which I had the privilege of being health officer. While I have always felt it to have been a great privilege to serve my people, especially you in New York, during such an interesting era, I feel no less proud that

This is introduced simply to illustrate the ease partments lined with white tile; and a disinfecting plant to which has been added a device for protecting bagagae sgainst damage from live steam, are features of this complete community shelter. Is one off the inhabitants ill, there is a hospital with a resident physician and a nurse attached to care for him. If the disease is a contagious one, there are special hospitals provided with modern equipment for his isolation and care. There are post and telegraph offices; a money exchange; a canteen; two hotels for the accommodation of those who wish to live in a more secluded maner and are willing to pay a mark, or twenty-four cents, a day extra for it; and two clothing stores; one for the sale of men's which any one can interpret regardless of literacy or language. On the sale of men's which any one can interpret regardless of literacy or language. The protestants. The Catholic church is equipped with all the paraphernalia required by the ritual, and masses are said four times a week. In the lewish section is a synagogue.

Each "citizen" pays about forty cents a day for the benefits of the Auswandererhallen. The institution is valuable to the steamship company also. It serves to keep the emigrant in a contented frame of mind and good physical condition.

No sooner does the emigrant reach the Auswandererhallen than the fitting of the paraphernalia required by the ritual of the fitting of the second of th

it happened during my régime that we were enabled to materially increase the quarantine facilities. When I assumed office I received from my predecessor the wholly inadequate islands in the lower bay and one faulty tug for boarding steamers. However, I was able to pass on to my successor in office Fire Island and the Surf Hotel, which alone could meet any emergency, also an appropriation secured from the legislature to extend Hoffman Island from two and one half acres to ten acres, i. e., to increase it to four times its size at that time; also three tugs, not only substantial, but in every other respect adequate for all future service.

But last and not least important was the promulgation and carrying into effect by the Secretary of State the regulation of inspection and detention at ports of embarkment, which are now in force, and which, if properly observed, will arrest the march

of any epidemic in the future.

RESTORATION OF SIGHT AFTER NEARLY A MONTH'S BLINDNESS FROM GLAUCOMA.*

By J. L. MINOR, M. D., Memphis, Tenn.

It is not so unusual to restore vision to an eye, blind from an attack of acute glaucoma, if the patient is seen early and promptly operated upon; but in the case I am about to relate blindness had existed for nearly a month, and it really belonged to the hopeless class. I never saw a case myself, nor do I know of one in literature, where, after so long a period of blindness from this disease, vision was regained by any means.

CASE.—Miss H., aged fifty-seven, referred to me by Dr. J. F. Cochran, of Memphis, was seen September 16, 1903, when the following history was elicited: While traveling in California, on July 5, 1903, she had a sudden and severe attack of pain in the left eye, lasting thirty-six hours. A few days later a like attack was experienced in the right eye, when it was noticed that vision was blurred in both eyes. Such attacks repeated themselves every few days, being usually worse in the left eye, and with each attack there came more impairment of vision, and by August 22d patient was totally blind, with more or less continuous pain in each eye. She was taken to an infirmary in Los Angeles, Cal., several weeks after the first attack, where she remained for a week or more, under treatment, when she was dismissed, with eserin drops to be used as demanded, which gave slight relief from pain, but had no effect on sight. Her case was pronounced hopeless as to vision, and operative measures were refused by the attending oculist.

operative measures were retused by the attending oculist.'
After this, the condition remained practically unchanged until I saw the patient. She told me that she could see, at times, large objects, but I found not even perception of light. The tension of the eye was +1. Scleral vessels, enlarged; anterior chamber, shallow; pupil, dilated; media so hazy that nothing more than a red reflex could be obtained. This description applied to both eyes. Pain was more or less constant and severe, and the natient was worn more or less constant and severe, and the patient was worn to a shred by her continued suffering and depression over her condition. The case presented a pitiable outlook, for vi we had been lost for a month, and the condition

pronounced hopeless by an oculist of repute. Moreover, this opinion had been rendered six weeks prior to my seeing her, when a clear media admitted a view of the fundus; and as, at that time, I was told that the oculist refused to operate, I naturally inferred there was some contraindication-probably a hæmorrhagic condition; hence I was in a serious dilemma as to what course to pursue. I was not serious dilemma as to what course to pursue. I was not long in deciding that iridectomy would hardly make her worse, and that it offered the only hope of relief from pain and the only avenue to possible vision. With the assistance of Dr. J. F. Cochran and Dr. Alfred Moore, and under cocaine anæsthesia, I performed an iridectomy, upwards, in each eye. The operations were smoothly persuance of the properties of the properties of the properties. formed and the customary dressings applied. The healing process was normal. No further pain was experienced. The eyes were dressed daily on account of a slight conjunctivitis, but not until the fourth day after the operation was there any effort made to test the vision, when it was was there any enort made to test the vision, which it was found that she could see and recognize faces some feet away. By the end of a week she could see the hands of a clock across the room and tell the time by my watch.

The first careful tests were made at my office, on October 13, 1903, with the following results: O. D. V. = 20/40 - 1.25 d. c. ax. 120 V. = 20/30. O. S. V. = 20/100 - 2.00 d. c. ax. 90 V. = 20/40. Visual field in each eye was concentrically contracted to a circle 10 degrees from the circle 10 degrees from th 90 V. = 20/40. Visual field in each eye was concentrically contracted to a circle 10 degrees from the point of fixation. The wounds had closed, with good keyhole colobomata. Media was clear. T. n. The ophthalmoscope showed in right eye, with the exception of the optic disc, a normal fundus. which could be seen with — 1 d. s. The disc showed general cupping of — 7.00 d., with kneed vessels, and was of almost atrophic whiteness. The left eye showed the same condition expect the supplies of the disc was less (fundus condition, except the cupping of the disc was less (fundus, - 2.00 ; disc, — 5.00)

I have seen Miss H. from time to time, at intervals of every few months, up to January 20, 1908. The right eye has retained its vision and visual field, and has remained unchanged up to the present time, except for the development of a small cystoid cicatrix at the upper and outer ment of a small cystola creatrix at the upper and outer portion of the seat of the corneoscleral incision, which was first noticed April 12, 1904, and has so remained since. The left eye, on March 16, 1905, could not be brought beyond 20/100. On January 18, 1906, vision was reduced to 20/200, and on October 30, 1906, it was, movements of hand at two feet, which it still retains at present. There have been no changes in tension or intraocular appearances.

RANDOLPH BUILDING.

THE VALUE OF THE X RAYS IN CHEST DIAGNOSIS.*

By A. L. GRAY, M. D., Richmond, Va.,

Rontgenologist to The Virginia and St. Luke's Hospitals: Professor of Physiology, University College of Medicine.

In the determination of conditions existing within the thorax, every procedure that will add to our very imperfect methods should be accorded a most hearty welcome.

While there are specialists who can, after years of the most assiduous application and wide experience in chest examination, recognize very slight abnormalities with a wonderful degree of accuracy, such men are rare, and often their findings are not treated with the respect due them, for the reason that the doctor referring the case is not sufficiently trained in physical diagnosis, and cannot himself detect the points elicited by the chest specialist.

There are conditions that, by reason of their size and location, even the most skilled physical diagnostician cannot possibly ascertain, while their recognition at the onset may mean the arrest of the disease before it is beyond control.

^{**}How at Linda now to a Only mologed Society, at New London, Conn., July, 1908.

**Continuation of the American Continuation of the Only State of the Continuation of the Only State of the Only

^{*}Read at a meeting of the Medical Society of Virginia, Richmond, Va., October 20 to 24, 1908.

It is my desire to call to your attention the applications of the x rays as an aid in discovering with accuracy points difficult or impossible of demonstration otherwise.

Thoracic Ancurysms.

Although an early diagnosis rarely, if ever, enables a complete cure to be effected, the patient's habits of living may be so modified, and treatment so instituted in consequence thereof, that life may be prolonged or even the progress of the aneurysm arrested.

A thoracic aneurysm found by the x rays in a woman in the sixth month of pregnancy caused me to advise the induction of miscarriage. The operation was successfully performed, and the patient spared a probable sudden death during labor.

Aneurysms have been often found when their existence had never been suspected, and the radiograph was made for an entirely different reason.

Pain in the region of the large bloodvessels, persistent aphonia or huskiness of the voice, bronchorrheea, areas of deep seated tenderness near the sternal or in the interscapular regions, when the cause is not clear, should always be suggestive of thoracic aneurysm.

Pleuritic Effusions.

Though these are usually easy of diagnosis, they are sometimes very difficult.

It has been my fortune to test the utility of the x rays in a considerable number of cases of hydrothorax and pyothorax, and in a single case of hæmothorax, the result of a bullet wound.

In hydrothorax, which is the most common of these, the level of the fluid, if it is not walled off, shows distinctly in the radiograph, usually as a fairly sharply defined line, above which are the shadows of more or less normal lung tissue, while below is the denser and more diffused shadow due to the greater difficulty encountered by the x rays in penetrating the fluid. The ribs appear much less distinct.

In localized pleuritic effusion, where adhesions have formed a distinct wall which encloses the fluid, the thickened pleura, as well as the fluid, is generally easily recognized. If the effusion is great, there appears in the lung tissue itself, especially in that portion near the fluid, an increased density due to compression.

What has been said of hydrothorax may likewise be said of empyema, except that the pus shadow is more dense than in hydrothorax, and often the shadows of the ribs are entirely obliterated.

Pneumothorax is readily determined by the absence at the site of the air, of even the normal

shadow of the lung.

Abscesses within the lungs are distinguishable by appearing as very dense, generally single areas shading off into the surrounding lung tissue.

A difficulty which occasionally presents itself is the risk that the patient may undergo in being placed in the upright position necessary in diagnosticating general effusions. Rarely, indeed, will a case be seen in which the danger would be too great to permit the sitting posture in bed for the short time necessary to take the picture. Such a condition,

however, does sometimes occur and renders the diagnosis of free fluid quite difficult.

Tumors and Enlarged Glands.

Tumors of the lung tissue generally produce dense, often sharply defined areas of more or less irregular outline, not infrequently multilocular. They may be distinguished from abscesses, which they most resemble, by the absence of fever, and by the result of the blood examination.

Mediastinal and bronchial glands appear as rounded or oval shadows with clear cut borders. They may, if large, be mistaken for small aneurysms, and must be distinguished, if there is doubt, by fluoroscopic examination, when the expansile pulsations may be seen.

Tuberculosis.

It is in tuberculosis that the x rays have begun to open a new field. X ray operators everywhere have in the last few years turned their special attention to the early recognition of this disease by radiographs. Many cases have been reported in which the chest specialist has failed to determine any physical signs—long before the appearance of the bacilli in the sputa—in which an unqualified diagnosis of pulmonary tuberculosis was made and the subsequent course of the disease verified the findings.

With the present, almost instantaneous, work that the recent machines are capable of doing, an exposure may be made while the breath is held, and the smallest area of consolidation will appear distinctly on the picture. Isolated tubercles, minute calcified glands, and thickening at the roots of the lungs can be clearly demonstrated. In advanced tuberculosis in which there is considerable consolidation, the areas may be studied and progress or recession of the disease determined by comparing radiographs made from time to time. Cavities in the lungs, their size, location, and whether or not they are being walled off are all points that may be shown by a good radiograph.

In chest examinations for tuberculosis it is not sufficient, as is often done, to make a single picture with the plate behind the thorax, for images of small, solid areas in the anterior portion of the lungs, may be indistinct by reason of their distance from the plate.

In order to obtain a clear impression, it is of equal importance that a picture be made with the plate in front.

Restricted motion to the diaphragm on the affecter side (Williams's sign) which was formerly considered of great value in the diagnosis of early tuberculosis, has been proved to be unreliable. This is easily demonstrable by an x ray examination, but is not always present in the earliest manifestations.

The heart may also be outlined, and its size and position ascertained. This is best done by the employment of the orthodiagraph, which also enables the diaphragm and other structures to be most accurately charted.

The location of foreign bodies in the œsophagus and respiratory passages is of such frequent occurrence as to require no comment in this necessarily brief paper.

312 EAST FRANKLIN STREET.

CONGENITAL NEPHRITIS.* BY HOWARD T. KARSNER, M. D., Philadelphia,

Demonstrator of Pathology in the University of Pennsylvania; Assistant Pathologist to the Philadelphia General Hospital. From the Laboratory of Pathology of the University of Pennsylvania and the Philadelphia General Hospital.

The following case is of interest not only because of its rarity, but because of its suggestions in the realm of ætiology of nephritis; for, although we all stand ready to credit nephritis to some very definite infection or to the presence in the body of some fairly well defined irritant whose nature we have at least approximately determined, yet the occurrence of this disease in the new born child of an apparently healthy woman leads one to think that the delicacy of this finely constructed gland may be susceptible to the irritation of many substances of which we have little conception at the present time. the kidneys of young children may become diseased because of the influence of an irritant which seems to be of little or no ætiological moment in adults is well borne out by reference to the literature. Acute indigestion and inflammatory conditions of the gut tract, cold plunges, exposure to high grades of heat, calcareous and hæmosiderin deposits in the tubules, interstitial hæmorrhage, and even icterus, in addition to the causes found in later life, such as passive congestion, ingested irritants and infections, have all been shown to play a part in the ætiology of nephritis of very early life (13). The delicacy of the infantile kidney is well shown when so simple a condition as vaccinia may produce nephritis (15). That uric acid infarcts may produce nephritis in very early life is well known (10), and that such uric acid infarcts may occur before birth has also been demonstrated (12). Parental syphilis as an ætiological factor in infantile nephritis, and even in the nephritis of premature and still born infants, plays an important part. Here, of course, the nephritis is most usually of the interstitial type, but in some cases in which purely parenchymatous changes have occurred the cause seems to have been undoubtedly syphilis. Spiess (19) noted this in 1877, Stroebe (20) again in 1891, and Cassell (7) in 1904 made a complete study of twelve cases of undoubted hereditary syphilis, the patients dying between the fifth week and the fifth month, and of six cases the patients being syphilitic and prematurely born. Ten of the twelve patients in the first group "showed more or less severe parenchymatous alterations which exhibited an extremely wide variation in extension and intensity." Of the six cases in the second group four patients showed severe alterations in the epithelium of the uriniferous tubules. In these cases, however, the glomeruli "showed no serious diseased process.

The case which I report is one of acute parenchymatous disease. I was unable to locate the father, but the mother's history and physical examination were negative, and the baby itself showed nothing to indicate syphilis. Baby and mother were on the service of Dr. Reynolds in the Philadelphia General Hospital. The autopsy on the baby was made during my own service in that institution. Dr. Reynolds and his resident. Dr. Jackson, have furnished me with the physical examination and the account of the birth, life, and death of the infant. History, physical examination, and autopsy report follow

E. B., white, thirty-four years; born in Ireland; occupation, housework; unmarried; was admitted to the hospital in the early stages of labor.

Family history: Father and mother dead of unknown cause. Three brothers and two sisters are all living and

well. One sister has five children, all living and well, and has suffered no miscarriages.

Previous personal history: Patient had mumps and measles in childhood and had suffered from no serious or long standing illness in adult life. Menstrual flow began at sixteen years and continued normally until last July. She denied having been pregnant before and denied ever having had intercourse before the one which caused the present pregnancy. She absolutely denied venereal history of any sort, although she said she had had slight attacks of leucorrhœa within the past three years. She denied using alcohol or other drugs, but is a moderate coffee and tea drinker.

History of present condition: Menstrual flow was last seen in July. Passed through the usual course of preg-nancy with its signs, except that the breasts did not enlarge appreciably.

Physical examination (by the resident physician, Dr. Jackson): Well developed, adult, white Irish woman of Jackson): Well developed, adult, white Irish woman of moderate stature. Eyes: gray, pupils react to light and accommodation. Tongue: coated and dry. Pulse: tension fair, slow, and of good volume. Head: negative. Chest: Negative. Abdomen: pendulous; foctal mass on the right, feet on left side. Vaginal examination: netlike processes about the orifice. Cervix soft, flattened and admitted two fingers. Extremities; negative. Ward Notes:

April 22, 1908. Patient went into labor at 3 a. m., mem-April 22, 1908. Fatient went into labor at 3 a. m., membranes ruptured at 8;30 a. m., child was born at 9;45 a. m., placenta at 10:15 a. m. Morphine sulphate, gr. ½; hyoscine hydrobromate, gr. 1/150; given hypodermically about one half hour before active labor began. Child born in left occipitoanterior position. Labor normal. Child apparently well developed, showing no abnormalities except cyanosis, which continued even after respiration had been established. A few minutes after cutting the cord the child became more deeply cyanotic, respiration failed, and the child died about forty-five minutes after birth.

April 30, 1908. Uninterrupted recovery on the part of the

mother. (Note: At about the time of death of the child the resident physician attempted to inject a small dose of strychnine directly into the heart, an attempt which was without observable effect.)

observable effect.)

The mother's urine showed a light yellow color, was clear, specific gravity, 1.015, contained a few epithelial cells and detritus, but no albumin, sugar, or casts.

Autopsy on the body of the child was made by me forty-eight hours atter death: M. B., aged forty-five minutes. Body of a white female infant, well developed and well nourished. Fairly good growth of light hair, with the general cutaneous redness of the new born. No apparent cyanosis. Primary incision showed nothing abnormal. On lifting the chest flap a needle puncture was found in the fourth interspace in the midclavicular line, which could be followed down into the lower lobe of the left lung without followed down into the lower lobe of the left lung without showing any evidence of having struck the heart or peri-

Abdomen: Abdominal cavity showed a smooth, glisten-Abdomen: Abdominal cavity showed a smooth, glistening peritioneum; normal situation of organs. Belly cavity contained approximately 100 cc. of clear, brownish yellow, limpid fluid. Spleen: Approximately of normal sizes smooth, glistening capsule; cut with ease and showed a moderately firm, slightly bleeding cut surface, without distinct markings. Left adrenal: Large, showed post mortem congestion. Left kidney: Weight, 20 grammes; measured 5x2.2x2.7 cm.; was markedly lobulated; capsule stripped with ease, showing a smooth, dark brown surface with intense congestion of stellate veins. The organ cut with ease and showed a slightly bulging cut surface; cortex measured 2.5 mm., entire kidney substance, 1 cm.; cortex showed 2.5 mm, entire kidney substance, I cm.; cortex showed marked congestion, little or no striping; pyramids considerably injected. Pelvis normal. Right adrenal was like tis fellow. Right kidney: Weight, 18 grammes; measured 1882/28/25 m., capsule stripped with case, showed a

grayish brown surface with injection of the veins not quite so marked as in the opposite organ; cortex measured 2 mm., cut with ease, showed a light, yellowish brown, moderately bleeding cut surface; entire kidney substance to mm; cortex was light in color and showed no stripings. Pyramids moderately injected. Bladder: Showed a normal mucosa; contained no urine whatever. Urachus, closed. Stomach contained a small amount of frothy mucus. Mucosa apparently normal. Intestines were considerably injected, particularly in the neighborhood of the Peyer's patches; they contained a large amount of dirty yellow, feecal ma-terial. Appendix was normal. Large intestine was distended with meconium. Liver was approximately normal in size; showed a smooth, glistening capsule; cut with ease, showed a slightly bulging, grayish brown, bleeding cut surface in which the markings were completely obscured. Gali bladder was distended with very viscid green bile; mucosa normal. Pancreas showed no gross anatomical change. Aorta was normal. Thymus was present, apparently normal.

Thorax: Right pleura was smooth and glistening throughout. Right lung was moderately crepitant; cut surface was light red, exuded on pressure a small amount of frothy white fluid. Left pleura was like the right. Left lung was like its fellow, except for a slightly bleeding puncture extending from the outer surface well into the lower lobe. Pericardium was smooth and glistening. Cavity contained 30 c.c. of clear, straw colored fluid. Heart was of normal size; musculature apparently normal; thickness of wall of the heart ventricles giving a ratio of about 1.2 (right to left); foramen oyale patulous; valve leaflets norin appearance and orifices of normal calibre.

Anatomical diagnosis: Congestion of lungs; puncture wound of left lung; patulous foramen ovale; acute diffuse nephritis; cloudy swelling of liver.

Sections were prepared and examined histologically from the following tissues: 1, Thymus; 2, lungs; 3, liver; 4, pancreas; 5, spleen; 6, kidneys; 7, stomach; 8, small intestines.

I. Thymus: The surrounding fibrous tissue was a thin I. Inymus: The surrounding norous tissue was a tinu layer of loosely arranged fibres, poor in cells, in several places including a few fat globules. The gland proper showed the usual lymphoid cells in the cortex with a looser arrangement in the medulla. The corpuscles of Hassall were numerous and discrete. No epithelium encountered. Vessels showed normally thick walls, but were densely engorged with erythrocytes. Cortex did not show demonstra-ble erythroblasts, but showed numerous mononuclear

eosinophiles.

2, Lungs: Pleura present, showing as a thin, loosely at ranged layer of fibrous tissue with somewhat congested ranged layer of history issue with somewhat congestive capillaries. Vesicles were moderately but universally distended, in some parts much more so than in others. No evidence of true exudate was found, although in some places the vesicles were filled with a finely granular substance which took the eosin faintly, probably serum. alveolar walls were moderately thick in the poorly expanded portion of the lung and about as thin as those of the adult lung in the well expanded portions. The thicker alveolar walls were made up largely of engorged capillaries, a few connective tissue cells with oval vesicular nuclei. A few lymphoid cells, plasma cells, and leucocytes were discernible as "were di were discernible, as were also the endothelial cells of the considerable as were also the endotheral cells of the engillaries. No evidence of excess of fibrous tissue elements could be made out. The bronchi showed slight clouding of the epithelium with loss of outline. Nuclei were sharply outlined, vesicular, and well stained. No desquamation or exudation. The larger vessels showed a rich supply of elastica, but were of normal thickness and wells are constituted were constituted to the control of make up. Congestion was general and well marked throughout the section.

 Liver: Capsule present and of normal thickness and ensity. Perilobular portion of capsule was also normal in thickness, but shows a few lymphocytes embedded in In the the thorn was a tew lymphocytes embedded in the fiborus meshes. Portal vein was normal; hepatic artery engorged with erythrocytes; bile ducts showed normal epithelium. The parenchymal cells were poorly outlined, granular, and poorly stained. Many of them contained minute vacuoles, probably of fatty origin. The nuclei were distinctly outlined, but faintly stained and vesicular. In many instances the nuclei were completely obscured. Definite karvertheyis and previous not demonstrable. The innite karyorrhexis and pycnosis not demonstrable. tervening capillaries showed numerous erythrocytes.

central veins were generally filled with blood.

4. Pancreas: The cells of the parenchyma were of about

normal size, but showed no distinctness of outline, and were somewhat granular. The nuclei were well stained, prominent, sharply outlined, and with normal chromatin arrangement. The islands of Langerhans were present in apparently normal numbers, their cells showed the same protoplasmic degeneration as noted in the parenchyma, the nuclei being normal. The interlobular interstitial tissue was present in comparatively increased amount, but showed young connective-tissue cells of the oval and fusiform vesicular type, in a relatively loose network of fibrillæ. The vessels were of normal size, but considerably injected throughout the section.

5, Spleen: Capsule and trabeculæ of normal thickness and density. The pulp showed the usual arrangement of fine stroma and small round cells, markedly admixed, how ever, with enormous numbers of erythrocytes which in many cases seemed to encroach upon the follicles somewhat. The follicles otherwise were normal in size, prominent, and showed normal elements. The vessels were universally distended with blood, but normal as to the walls.

6, Kidneys: Capsule almost completely stripped, leaving only a few fibrillæ on the surface. The glomeruli were of a size that could be considered normal for the time of life of the patient. The number of nuclei was markedly inof the patient. The number of nucies was markedly increased, they being for the most part oval, circular, or occasionally spindle shaped, well stained, sharply outlined, distinctly vesicular, and with a netlike arrangement of the chromatin. The capillaries showed the presence of a moderate number of crythrocytes. The capsular epithelium was normal. The capsular space was almost completely obliterated by the enlarged tufts and showed no appreciable exudate. The epithelium of the convoluted tubules was swollen, had completely lost outline, and was distinctly granular. In many tubules the lumen was obliterated by the swelling, in others the lumen was filled with granular detritus. A few vacuoles very suggestive of fat could be made out in the basilar portions of the cells. The nuclei showed various degenerative changes, in some cases staining diffusely blue with the hæmatoxylin, in others showing a peripheral accumulation of chromatin. Many nuclei were obscured either partially or completely, but no fragmentation obscured either partially of completely, but no fragmentation was demonstrable. The tubules of the rays and the medulary tubules showed much less protoplasmic degeneration and normal nuclei. The blood vessels showed normal walls, but veins, arteries, and capillaries were markedly congested. The interstitial tissue showed no proliferation. In a position corresponding to the pelvic side of the sections was found a large mass of fairly dense fibrous tissue covered

with transitional epithelium, the infantile pelvis.

7, Stomach: The nucosa was of normal thickness. The glandular epithelium showed typical goblet cells formation, grandiar epinenum snowed typical goolet cens formation, and there was finely granular material in the lumina suggesting the presence of mucus. The deeper epithelial cells showed granularity, swelling, loss of outline, and small vacuoles, probably of mucus. The nuclei were normal. The interstitial tissue of the mucosa was normal, save for the infiltration of a very few round cells. Muscularis and peritoneal coats were normal. The vessels of all the coats were moderately engorged with erythrocytes.

were moderately engorged with erythrocytes.

8. Small intestine: The epithelium had disappeared, probably because of post mortem digestion. The villi showed some degeneration of the outermost cells, and there was a slight round cell infiltration. The submucosa showed at one point a large collection of lymphoid cells, which was not sharply outlined, but spread out into the surrounding tissue. The remainder of the submucosa was normal. Muscularis and peritoneal coat were normal. The vessels generally were moderately congested. Histological diagnosis: Normal thymus: congestion of lungs; advanced cloudy swelling of liver; interlobular fibrosis in pancreas; congestion of spleen; acute parenchymatous nephritis; mucoid degeneration of gastric mucosa; slight lymphoid infiltration of small intestine.

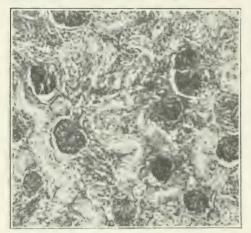

This history showed nothing in the mother that I can definitely blame for the repliritis in the child. The fact that she was unmarried suggested the fact that some drug might have been used to induce their tion, and my attention was particularly directed to potassium chlorate as an inducer both of abortion (12) and of nephritis, but the history showed nothing of this.

the cause of the nephritis except the slight lymphoid infiltration into the submucosa of the small intestine, which in view of the work of Jacobi (16) and of Holt (14), and associated as it was in this case with a parenchymatous degeneration of the liver, would suggest the possibility of some feetal intestinal disturbance as having induced the kidney condition. With the absence of any splenitis and the absence of anything in the gut to indicate definite intestinal disease I cannot consider these conditions as having more than a suggestive significance.

The general congestion of all the viscera, I believe to have been purely postnatal, since there was no vascular thickening, no evidence of diapedesis or hamorrhage, and no interstitial proliferation (except in the pancreas); hence it was probably of insufficient duration to have produced any inflamma-

tory kidney condition.

Syphilis is naturally the disease to which we look as the most likely cause of the condition, but there were no cutaneous bullæ, no enlargements of the

Section of kidney, howing by the deep tone of the glomular tufts the marked proliferation of the nuclei.

bone ends (no sections made), no interstitial overgrowth in the lung, a liver that showed a normal capsule of Glisson, and no changes in the kidney that could be considered indicative of nephritis. The pancreas showed moderate interlobular overgrowth of connective tissue, a condition which can occur quite independently of syphilis and which has been so reported (18).

Parenchymatous disease of the kidney, as I have stated before, occurs in syphilis of the new born and of the fœtus, but such conditions are by no means diagnostic of syphilis. Cassell (7) says, "In reference to the diagnostic interpretation of these (parenchymatous) alterations in connection with syphilis I had an agreement with Hecker when I say that we must not see anything pathognomic or diagnostic of syphilis in these degenerative conditions."

Hence I am led to believe the disease in this particular infant was in all probability of the type that Holt (13) speaks of as primary nephritis.

For justification of such a classification of this case I refer to Ballantyne, who in rather general consideration of The Pathology of Antenatal Life (4) says: "During feetal life the organism is subject, just as it is in later life, to the maladies which are caused by microbes and their toxines, and by poisons, mineral and vegetable; it may also be affected by diseases which, in the absence of fuller knowledge, we must call idiopathic. . . . So far therefore as our knowledge of the pathology of postnatal and antenatal life has carried us, it would seem that the same morbid causes are in action in all the periods into which the existence of the organism has been divided."

In how far the kidney condition was responsible for the death of the baby is hard to judge, when we remember the fact that this infant was apparently a "blue baby" and had a wide open foramen ovale. Of course, during feetal life the activity of the kidney is not great, and we must consider the possibility of the changed conditions and activities of life having produced such an increased demand on the function of these diseased kidneys as to have completely disabled them. The infant's bladder was empty, but that may have been brought about by the usual urination which occurs soon after birth. It is hardly probable that a toxemia sufficient to cause death would occur in forty-five minutes, yet we must conclude from the pathological condition of the organs that the kidney insufficiency must have had a considerable duration, and that some more or less marked grade of toxæmia must have existed prior to birth. In that case the additional toxæmia attendant on the increased functions of postnatal life may have been just sufficient increment to cause death. In such cases "it may be said that the cause of death is birth."

A careful search of the literature shows a surprising meagreness of information in reference to nephritis in infants as young as this. Many standard textbooks of pædiatrics and pathology fail to mention that such a condition may occur. Many of the more modern authorities mention the primary nephritis of the new born, but seem to think of it as a condition limited to postnatal life and do not suggest the possibility of its being present at the time of birth and of its having originated in antenatal life. On the other hand, Descroizilles (9) mentioned it as early as 1883 as occurring "in the first days of ex-Cotton (8), Baginsky (3), and Henoch (11), all draw attention to it, the last named in particularly forceful fashion. He says "one sometimes meets with cases of most tender age in which nephritis has developed and has resulted disastrously without any cause for the condition having been discovered. I do not mean here the cloudy swelling of the cortex which often appears as a result of the disturbance of epithelial nutrition, but clinically recognizable pictures of inflammation." Ashby and Wright (2) make even a more positive assertion, saying that "in rare cases infants are born with acute nephritis," and refer to the case which is the third and most definite of the three cases that I have collected, i. e., cases which have truly been born with

the aid of the mechanical stage. The result was negative. While this negative finding is by no means conclusive, yet it may be ac-

CASE I .- This is Cahen's (5) case, reported in 1853, a case which was probably, but not certainly, nephritis; I quote from Cahen's paper: "Observation IV. A male infant of two days, not having reached term, weighing 1,000 grammes, and of forty-two centimetres total length, died suddenly as a result of convulsions on April 29, 1851. At the autopsy the principal organs were found to be normal. The kidneys were congested, one weighing seventeen grammes, and the other fourteen grammes. A few drops of urine found in the bladder gave a white precipitate of albumin."

Case II.—Kast (17) described and pictured the gross appearance of a kidney in which histological section would probably have shown the changes of a nephritis subsequent to congestion. His report follows:

to congestion. His report follows: "Cyanotic kidney in a new born. Body of an extremely cyanotic child which died during birth. All the organs showed intense venous congestion; multiple ecchymoses up to the size of lentils on the serous membranes. absolutely unexpanded. Kidneys showed marked foetal lobulation. On the cut section the black blue colored pyramids were sharply demarcated from the homogeneous light red cortex; the deep blue color of the pyramids was seen throughout their entire extent, and by close inspection was seen to be brought about by a recognizable tense injection of the venous channels up to the borderline.

Tagetion of the venous chainers up to the boldering.

Case III.—Ashby's (1) case as quoted in Carpenter's article (6) is probably the most definite and certainly the most interesting case that I have found. Carpenter says:

"Ashby records the case of an infant, aged four weeks, which became dropsical the day following its birth and remained anasarcous to the day following its birth and fle-mained anasarcous to the day of its death, and finally died in convulsions. The kidneys were pale and showed but little distinction between cortex and medulla. Microscopically, there were extensive epithelial and fibroid changes, and the small arteries appeared thickened. There was no evidence of syphilis, although he thought that suggestion worthy of consideration, but to him it appeared to be the exact type of scarlatinal nephritis.

I firmly believe that such cases as this of Ashby's and the one that I report, although at the present time to be classified only as primary nephritis, have most certainly been caused by some nephritic irritant the nature of which we do not know, but just as surely as there will come a day when there are no primary anæmias, so will a day come when the term primary nephritis will have become historic rather

than practical.

REPORT OF A GLIOMA OF THE BRAIN INVOLV-ING THE PIA MATER.

By I. STRAUSS, A. M., M. D.,

New York,
Instructor in the Department of Pathology, Cornell Medical College;
Associate in Neuropathology, Mount Sinai Hospital.

The general conception of glioma held by practitioners and even by some pathologists is that the tumor takes its origin in the central nervous system from glia cells, which infiltrate, but generally do not destroy the surrounding nerve tissue; the tumor remains confined to that tissue and does not While these characteristics are form metastases. true for the majority of such growths, they no longer hold for all of them. Mallory has reported a glioma arising outside the central nervous system which formed metastases. Some of the ependymal gliomata cause multiple growths in the ventricular

It is held that the gliomata do not grow beyond the brain and cord, or, to be more precise, that they do not infiltrate the meninges. It is for the purpose of clearing away this misconception that this

paper is written.

Schlesinger in his comprehensive monograph on Spinal Cord Tumors, which was published in 1898, makes no mention of gliomata growing diffusely

from the brain into the meninges.

Bruns in his book Die Geschwülste des Nervensystems, published in 1908, page 10, says: "The infiltration of the pia by a glioma scarcely ever happens; it halts at the pia. Rare exceptions may occur; indeed Pels-Lensden has observed the invasion of the pia by a central glioma of the cord."

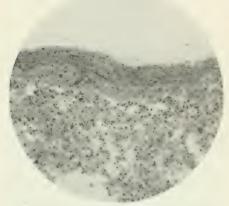

As recently as in one of the July numbers of the New York Medical Journal of this year, Mayer and Proescher, in their report of a glioma of the brain, make the statement that gliomata never extend to the meninges of the central nervous system.

It is astonishing that such statements occur so frequently in view of the large number of cases reported in which the infiltration under discussion has

taken place.

Saxer has observed the glia tissue growing into the pia in a case of syringomyelia, thus showing the possibility of glia growth, although possibly not of a true glioma. Alzheimer has called attention to the fact that glia fibres frequently invade the pia in cases of general paresis. The oldest known case of tumor infiltration is that of Klebs, who describes an invasion of the pia, adjacent to a glioma of the cerebral cortex, by glia cells. The first important observation is that of Pels-Lensden, to whom Bruns referred, who reported a glioma of the cord which infiltrated the meninges of both cord and brain.

Frank and Benda have observed a case in which a central tumor located in the dorsal region grew out into the pia and surrounded the entire cord. The third case is that of O. Fischer, in which the tumor occupied the entire lumbar and sacral regions and parts of the dorsal and cervical segments and of the brain. The tumor had infiltrated the pia in a diffuse manner as high as the cervical cord. In Roux and Paviot's case there was a tumor in the cervical region which grew out into the pia and infiltrated the meninges of the entire cord. Grund reports a case of glioma in the lower and middle

I to, 1.-Shoaing infiltration of pix by growth. + 125.

cord which extensively infiltrated the pia mater. Spiller in a note to the Deutsche Zeitschrift für Nervenheilkunde, xxxii, calls attention to Grund's omission of a case reported by himself and Hend-Their case was one of a growth in the rickson. cord with diffuse invasion of the meninges. In the original article the authors stated: "There is unquestionably a close resemblance between these cells and those of the ependyma, and the temptation, therefore, is to call the tumor an ependymoma; but it seems remarkable that an ependymoma being a form of glioma should give extensive metastases to the pia of the spinal cord.'

The most recent case is that reported by Martens and Seiffer. It was an ependymal glioma arising in the fourth ventricle with multiple growths in the lateral ventricles. The growths in the fourth ventricle had infiltrated the pia over the cerebellum.

All these are the authentic cases of gliomata reported as growing into the meninges. Gliosarcoma or diffuse sarcoma arising in the cord and brain has long been known to infiltrate the meninges. Grund found that thirty-nine such growths with meningeal infiltrations have been reported, and described either as round cell, or spindle cell sarcoma, or as alveolar sarcoma, angeiosarcoma or endothelioma. Undoubtedly many of these if studied carefully to-day with newer technical methods and stricter regard for the conception of sarcoma would prove to be gliomata. It has been objected that some of these growths have originated in the meninges and grown into the cord, but Schlangenhaufer has shown that in most cases this assumption

The history of my case is as follows:

K. A., age seventeen years; was admitted to the service of Dr. B. Sachs, to whom 1 am indebted for the clinical history. March 22, 1907.

Previous history.-She had measles and scarlet fever

when a child. She had never had convulsions or periods of unconsciousness. There was no history of syphilis. She had not menstruated. She said her eyes had always

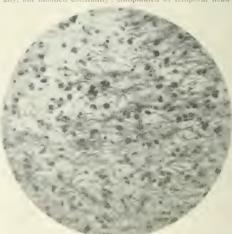

been somewhat prominent.

The present illness began eighteen months ago with attacks of headache, nausea, and vomiting. The headache lasted for several hours. These attacks occurred every two or three days for about two months. She went to work but could not do as well as before the onset. She was clumsy and slow in her movements and not mentally as bright as she had been. Three months ago she began to have headches again. They were bilateral and located in the temporal region. They occurred generally in the forenoon. There was no vertigo. She stated her sight, hearing, and speech were normal. She had not been in

The physical examination. March 23d, was as follows: Patient was well nourished. There was marked exophthalmos, especially of the left eye. The eyes appeared to be set far apart. Von Gracfe's symptom was well defined. There was divergence on accommodation. The pupils were equal and reacted to light and during accommodation. There were no palsies. The patellar reflexes were increased. Ankle clonus was present. The head appeared to be early and or accommodation of the property of the participation of the property of the participation of the property of t to be enlarged and measured fifty-five centimetres at the occipitofrontal level. Bilateral Macewen sign was present. On this same day and eight days later, each time at 7 a. m., the patient had a paroxysmal attack, which was

characterized by general rigidity, dilatation of the pupils, and bradycardia. These attacks were of short duration and followed by deep sleep. At 9 a. m. she began groaning and became restless. She answered questions. The face was pale; pupils contracted. There was vomiting; cyanosis of the extremities with a small and rapid pulse.

On April 4th, it was noted that the patient talked rationally, but mouned constantly; complained of temporal head-

the college three materials

ache. The deep reflexes were increased; no Babinski sign. There was weakness of the external rectus of the right eye. Dr. May's examination of the fundi showed a postneuritic atrophy of both.

April 10th.—The strabismus was more marked, and the

exophthalmos was more prominent.

May 3d.—Vision was lost. The mental condition was bordering upon dementia. The eyes were more prominent. Slight left facial palsy. Patient was unable to stand. The

Significant factor passy, rattern was unable to stand. The radiograph showed no tumor.

On May 24th a decompressive trepanation on the left side of skull was done without revealing the tumor.

May 20th.—The same was attempted on the right side; the patient's condition remained practically unchanged; remained in deep stupor, death occurring on June 18th.

The patient first presented general symptoms of

cerebral disturbance, such as headache, vomiting, and nausea, occurring in attacks for a period of two months. These attacks were probably due to the closure of the foramen Magendii with subsequent internal hydrocephalus. There followed an intermission of fifteen months, during which period slight mental apathy was the only symptom. It is possible that during this time either there was no increase of the hydrocephalus and there was an acquired tolerance of the brain to the pressure, or the foramen had become patent in some inexplainable fashion, or the circulation had been reestablished through some other channel than the foramen and the two lateral ventricular clefts of Key and Retzius. After this period, the symptoms of pressure recurred, and with them the symptoms of disturbance of the blood circulation at the base as shown by the exophthalmos. It was impossible from these symptoms to make a certain distinctive diagnosis between internal hydrocephalus and hydrocephalus caused by a neoplasm or by cysticercus of the fourth ventricle. Assuming there was a neoplasm, its definite localization was impossible. though the presence of exophthalmos and the later involvement of the nerves governing the eye muscles made it seem most probable that a tumor mass must lie in the region of the chiasm. This was afterward actually found to be the case. The two operations were performed more with the hope of giving relief to the patient from the symptoms due to intracranial tension than of localizing the growth.

Autopsy findings.—The convolutions were flattened. The lateral ventricles were very much dilated and contained a considerable quantity of cloudy fluid. On the base of the brain was a covering of newly formed tissue. The growth had the appearance of a thick, inflammatory rine growin had the appearance of a thick, inhammatory exudate located in the pia. It was very gelatinous, translucent in places, and of a grayish color. In some parts it was necrotic and in others showed evidences of old and recent hæmorrhages. It was nowhere adherent to the dura, but was so intimately incorporated with the pia that it was impossible to distinguish one from the other. The growth stripped off from the brain cortex as does the The growth stripped off from the brain cortex as does the pia normally, and except in the region of the chiasm it had not infiltrated the brain substance. The lower limit of this tissue extended to the medulla at the level of the crossing of the pyramids, and anteriorly it extended to just in front of the optic chiasm. It covered the pons, the crura cerebri, the tuber cinereum, the infundibulum, and completely obliterated the optic chiasm. The neoplasm had grown into the pontofacial angle, and surrounded both fifth nerves, especially the left. The right third and optic nerves and both fourth nerves could not be solated. Occupying the position of the infundibulum there was a mass of ordematous tissue about the size of a wal-nut, which reached up into the brain. It extended up-ward into the third ventricle, which it almost entirely occluded. Thence it had grown back through the iter into the fourth ventricle which was likewise almost completely filled. From the third ventricle, the tumor had passed through the foramina of Monro into both lateral ventricles, but more especially the right, where the gelatinous mass was attached by a pedicle to the inner wall just in front of the pillars of the fornix. This appeared to be the total ventral the same than the same places where the same and the same places. to be the only place where there was a connection be-tween the growth and brain substance proper. The growth had encircled the blood vessels at the base, especially those of the circle of Willis.

Microscopical examination.—The appearance was that of Microscopical examination—The appearance was that of the typical and common form of glioma (Figs. 1 and 2). The stroma of the growth consisted of the numerous processes of characteristic glia cells. There were also many glia fibres which seemed to have no connection with the cells. Giant multinucleated gila cells were likewise present. In parts of the growth the blood vessels were very numerous and they usually had rather thin walls adja-cent to which was the glia in characteristic fashion. In places there were hæmorrhages, both recent and old, as well as necrotic areas.

Sections of the growth were submitted to Professor Mallory, of Harvard Medical School, and he confirmed

the diagnosis.

The origin of the growth was from the wall of the The origin of the growth was from the wall of the ventricle, most probably from the wall of the right, to which it was attached. The gliomata which arise in the ventricles are those which take their origin from the subependymal glia. These tumors, however, are much more cellular than the one herein described and have very little or almost no stroma. The cells likewise generally have the character of the ependymal cells. This growth had none of these characteristics, but resembled much more those gliamata which arose from the glia of the brain. those gliomata which arose from the glia of the brain substance beyond the ependyma. While the manner in which the tumor invaded the pia was very unusual, the growth resembled other gliomata in the manner in which the surrounded the nerves and blood vessels without impairment of their function. Although all the cranial nerves, except those arising from the medulla, were surrounded by neoplasm, only the second and right sixth were much affected. And the atrophy of the second was probably due primarily to a neuritis caused by the internal hydrocephalus and not to trauma from the growth.

LATE REPORT OF A CASE OF FRACTURE AND DISLOCATION OF THE SECOND CERVICAL VERTEBRA.

By CHARLES D. Fox, M. D., Philadelphia, Pa

In view of the great rarity with which we encounter patients who have survived fractures of the cervical vertebræ, such cases are interesting and should be reported.

Fractures and dislocations of the first, second, and third cervical vertebræ almost invariably cause immediate death, and are most frequently the result of hanging, diving in shallow water and striking the head on a sandy bottom, or from some heavy object striking the head with great force in the

direction of extension.

The following history was taken September 13. 1907, in the nervous department of the Dispensary of the Hahnemann Hospital, of Philadelphia:

CASE—The patient, J. G., et chirty two, an intelligental breed Indian, was well until July, 1904, when 940 pounds of beef fell fourteen feet, striking him on the vertex and forcing his head backwards. He fell to the ground unconscious, remaining so for from five to eight hours, and

¹I am indebted to Dr. F. S. Mandlebaum, pathologist, for the photomicrographs.

was taken to the University Hospital. No operation was performed, but extension was applied in bed for two months. Following this he was kept in a plaster cast for three months, at first in bed, but later in a chair. Then an apparatus was made for him, with a jury mast, and he was treated as an ambulatory patient until eight months ago, when he discarded the apparatus except for short periods when the pains were severe.

The patient stated that for the first two weeks, following

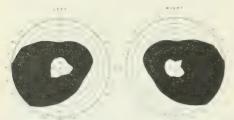

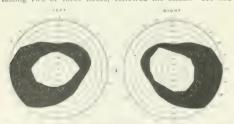

Fig. 1. The degree of concentric contraction of the visual fields present at the time (1) the first examination, September 13, 1907.

the accident, he was totally paralyzed in all of his limbs. During the first six months he complained of involuntary urination. There was not any dribbling of urine, but he did not know when his bladder was full. At present he knows when it is distended, but cannot hold his urine longer than a minute after the first impulse to urinate. For the last year he had not known when his rectum was full, and there occurred involuntary defacation. For about two and a half years his sexual desire was lost, and at present is very feeble. There had not been any erections since the accident.

He asserted that the pain, temperature, and tactile senses were lost for an indefinitely long period, indefinite because of the very gradual and incomplete return of these senses. His usual weight was 220 pounds, but three months after the accident it was 90 pounds, and at present 140 pounds. During the first three months that he was out of bed he had static ataxia, severe enough to cause him to

fall, even when his eyes were open.

About eighteen months ago, or twenty months after the injury, attacks as follows first appeared: The aura consisted of a sense of coldness of the scalp, vertigo, scintillating scotoma, tinnitus as if a bell was ringing, and a rancid taste. Any one or all of these symptoms might be present, lasting about three minutes or less and being followed by loss of consciousness and falling to the ground. While unconscious, usually about ten minutes, there were tonic and clonic convulsions, involuntary urination and defæcation, and biting of the tongue. A stuporous condition, lasting two or three hours, followed the attack. He had

It is the result of errortin elsemation, November 25, 1907.

taken strontium bromide for six months, at present in five grain doses, in solution, three times daily. In all he had had six convulsions with a progressive decrease in the length of the intervals

During the last six or eight months he had had attacks of petit mal, spontaneously, and whenever he closed his eyes, or was in the dark. Following an aura similar to that of the major convulsions he felt as if falling, or as if some great distance separated him from his body. In fact he

asserted to have frequently seen his body from a great distance. In addition he experienced numbress and tingling of the skin, dyspnca, palpitation, and a sensation as if his nose was bleeding. He never fell unless unable to hold on to some support. The attacks occurred about two or three times a day and lasted about two minutes. There apparently had never been any tendency towards the development of ambulatory automatism. During several attacks that I witnessed his eyes were closed, the face was expressionless, and there occurred slight twitching of both hands with moderate general rigidity.

At present he complains of a progressive failure of vision, dating from the injury, and of numbness of the fingers, toes, back, left side of face, and of the whole of his chin. He has also noticed irritability and impairment of memory not progressive and more marked for recent events. At night he rests in a steamer chair, as the pains in his neck are more severe when his body is in a horizon-tal position. Sleep occurs after a long interval, is very light, and he states that it lasts only about three or four hours. It is always accompanied by dreams, but the character of these is not of any interest to us. At times he has auditory hallucinations of singing, always by the same young, unknown female voice. This singing, possibly a psychic equivalent of a convulsion, has no fixed relation in time to his epileptic attacks nor is it a symptom of them.

His former occupation had been that of a cowboy and a special officer. Judging from the present size of his muscles and frame, together with his appearance in an old photograph he showed me, he must have formerly been a very well proportioned and powerful man. Knowing thoroughly the gravity of his condition and that at any time during a convulsion he may so injure his neck as to cause

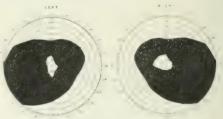

Fig. 3.—The retrogressive changes in the visual fields following the attack of meningitis.

instant death, he became quite indifferent and appeared to care little whether he lived or died. He denied the use of alcolol, but admitted to having had a venereal sore four and a half years ago which, judging from his description, was probably a chancroid.

The first physical examination, made September 13, 1907 showed his pupils to be equal, moderately large and reacting well to light, accommodation, convergence, and consensually. The external ocular muscles functionated well and without any nystagmus. Figure 1 shows the marked concentric contraction of his visual fields present at this time. Vision was 0. S. 3/70 and 0. D. 3/50. The eye department reported his discs to be practically normal. The muscles of the face and tongue functionated normally. All the muscles of the upper extremities were symmetrically very weak, but those of the lower extremities were revery weak, but those of the lower extremities were remarkably strong, and he asserted to be able to walk ten miles a day without any great fatigue. Tenderness was elicited in all the nerve trunks. This, he said, had been present for five or six months, or since "his feelings had returned." The tactile pain and temperature senses were very much impaired over the entire body and in some areas absent; but these defects were not apparent in the lower extremities. Astereognosis was present, that is, he could recognize the qualities of an object felt but could not name it or give its uses. The speech faculties were normal. With his eyes open there was slight static ataxia, but when closed the ataxia was severe enough to cause him to fall. were not any signs of incoordination of the upper extremities. The biceps and triceps jerks were present and the patellar, Achilles, cremasteric, epigastric, and gluteal reflexes were normal. The plantar reflex was almost absent and Babinski's and Gordon's signs were negative. Atrophy,

contractures, and spasticity were not demonstrable. Palpation of the skull disclosed a depression over the apex of the occiput measuring about one inch in width by two inches in length. The first and best radiograph made showed a fracture and slight angular displacement in the body of the second cervical vertebra, but unfortunately the patient had an epileptic attack while carrying the plate, resulting in its destruction. Closure of his eyes for tests in the above physical examination caused two attacks of petit mal.

From September 13, 1907, until January 7, 1908, he was treated at regular intervals in the nervous department, but his epileptic attacks steadily increased in frequency, in spite of the administration of strontium bromide in doses of from eighty to a hundred drops of the saturated solution three times daily. The onset of symptoms of severe gastric irritation prevented any further increase in the dose. During this period of fifteen weeks he had seven major convulsions and many of the minor attacks. For the possible relief of his pains he was advised to resume wearing his apparatus, which he had discontinued for some time, though little benefit resulted at first. Figure 2, taken November 25, 1907, shows the marked improvement that occurred in

the visual fields.

On January 7, 1908, he complained of having seen and to be dead, including his father, two brothers, and a friend. He asserted to have been subject to these hallucinations for the last seven years. These occurred only as he dozed and were accompanied by a sensation as if falling and followed by confusion and depression. He fully realized that these occurrences were purely subjective and thought that they were due to his having thought about his father and others before going to sleep. The voices never gave commands or revelations. It might be of interest to note the fact that the patient was a believer in the occult. The characteristics of these atacks would lead one to suppose that they were psychic equivalents of epileptic convulsions. February 18, 1908, immediately following a convulsion, he had a visual hallucination. Thinking he saw a man leave his room, he searched the house before coming to the conclusion that it was hallucinatory.

February 27, 1908, he stated that the preceding day severe pains had appeared in the back of his neck, both legs, and back, rapidly becoming more intense and preventing any sleep at all that night. In the morning, when he stood up, his legs were so weak that they gave way under him and he fell to the floor. He also complained of a very bitter taste, gastric pains, and a very severe paroxysmal headache, as if the top of his head was coming off. There was not any incontinence, but he said that he couldn't hold his mine after the first impulse to urinate. The cervical pains must have been very severe for, stoic as he was, the tears were running down his face while being examined and he admitted having cried all night. At this time the pupils were equal, normal in size, but reacted sluggishly to light, accommodation, convergence, and consensually. There was marked limitation of ocular movements in all directions and incomplete bilateral ptosis. The visual acuity was O. D. 3/70 and O. S. 3/70, showing a marked reduction in comparison with the acuity of O. U. 12/10 obtained three days before. His tongue was heavily coated, dark brown, and the breath was very offensive. Kernig's sign was elicited bilaterally, and there was a great reduction of strength of his whole body associated with a slight amount of spasticity. The pulse was 120, and the temperature by mouth 98.6° F. Because of his serious condition he was admitted to Hahnemann Hospital February 27, 1908, but left the next day in order to collect it in person that day. When warned of the daingers of leaving the hospital he laughed, saying that it made no difference to him whether he lived or died, and that if he lived to get to the home of some of his friends he would remain there even if without proper attention rather than go to any hospital.

Following this I attended him at his friend's home, where he was confined to bed. His condition became more serious and at one time he had a series of major epileptic convulsions, forming a status epilepticus, which lasted for several hours, in spite of the fact that he was taking 270 drops a day of the saturated solution of potassium bromide. For several days he was unable to move his limbs or even protrude his tongue. The highest temperature noted was 102.5° F. At one visit I decided that he couldn't possibly

live over twelve hours, but fortunately did not express this opinion.

About the middle of March he began to improve and on April I, 1908, to my great surprise he staggered into the dispensary, with the aid of a cane, saying that he felt almost as well as before his attack of illness. He stated that there was a total amnesia from the time of his entrance into the hospital, February 27th, until about the middle of March, and that a sudden twist of his neck accompanied by a sharp crack audible to others, a subjective sense as if shot in the vertex and severe epistaxis, ushered of amnesia, when visiting him, I noticed a great change in his personality. Normally he impressed one as being a Caucasian, but at this time one seemed to be talking to an Indian. He continually expressed a desire to be out in the open air, saying that if he were out on the plains sleeping on the ground he would surely get well. Also that the Indian medicine man possessed remarkable powers, hypnotic and otherwise, unknown to the whites, and these powers had been known and used for centuries. Confine-

Fig. 4 — Photograph taken September 20, 1007, showing the amount of flexion of the patient's neck that was present even during attempts at extension.

in the change to his normal personality. During this period ment in the house would kill him, but he wouldn't allow himself to die, and many times he swore he would surprise me by walking into the dispensary well some day. The character of his conversation was most impressive, and at times beautiful. It is unfortunate that circumstances at that time did not permit me to visit him more frequently and to examine with more detail his condition, especially this apparent dissociation of his personality.

and to examine with more decay, this apparent dissociation of his personality. Physical examination, made during his first visit after the illness, showed his pupils to be dilated and almost inactive, associated with paralysis of both superior recti, the right external rectus, and the left internal rectus. Figure 3 shows the retrogressive changes in his fields. The glossal muscles functionated well, but there was a weakness of the left facial muscles. His strength was very much reduced in general. The patellar reflexes were very much exaggerated, but no spasticity could be elicited. Kernig's sign was present, and also a slight static ataxia.

He was last seen by me in August, after he had returned from a trip to the west, and he was then in about the same condition as he was prior to his recent illness.

Note.—While walking along the street on August 30, 1908, the patient was suddenly seized with severe abdominal pain. He fell unconscious, vomiting began, rapidly becoming feed in character, and he was taken to the terman Hospital, where an instance is a right strangulated inguinal hernia was performed. The recovery properties of the properties of the statement, and the wound healed in four weeks without any complications having occurred. Feed

operative results that we cooltained are of interest because, on account of possible trophic changes, they could hardly be expected in

After consideration of the history of this case, the signs and symptoms present, and the results of radiographic examination, the diagnosis was made of an old fracture dislocation of the second cervical vertebra, complicated by an ancient depressed fracture of the skull. In addition, the patient suffered from major epileptic attacks, without any focal symptoms, and petit mal. His recent attack would seem to be an acute cerebrospinal meningitis of unknown type and origin.

The medicinal treatment he received, while under my care, had been almost exclusively with bromides for the possible relief of his convulsions. Hypnotic suggestion, carried to the stage of somnambulism, was employed for over four weeks, with no apparent effect on his convulsions, but being of great benefit in the relief of insomnia, pains, and other symptoms. This was most noticeable during the attack of meningitis, for on several occasions when the headache and pains were almost unendurable I kept him in the hypnotic state for a half hour, and on one occasion as long as two hours. Immediately upon the production of hypnosis his pains would entirely disappear and would not return for perhaps twelve hours.

2126 PINE STREET.

Our Readers' Discussions.

A SERIES OF PRIZE ESSAYS.

A SERNES OF FRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXX—How do you treat asphyxia neonatorum?

(Closed November 16, 1908.)

LXXXI.—How do you treat chronic eczema? (Answers due not later than December 15, 1908.)

LXXXII.—How do you treat chronic lead poisoning?

(Answers due not later than January 15, 1909.)

Whover unswers one of these auestions in the manuer

"Answers due not later than January 15, 1909.)

Whoever answers one of these questions in the manner
most satisfactory to the editors and their advisers will
seceive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely
on the value of the substance of the answer. It is requested
(but not REQUINED) that the answers be short; if practicable, no one answer to contain more than six hundred

All persons will be entitled to compete for the prize, whether subscribers or not. This prize voil not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXIX has been awarded to Dr. Samuel Salinger, of Chicago, whose article appeared on page 1037.

TREATMENT OF SICK HEADACHE.

Dr. Franklin C. Clark, of Providence, R. I., re-

No special law can be laid down for the treatment of migraine, the hemicrania of medical writers, the name which covers the vast majority of cases of sick headache. As the female sex constitutes the great bulk of its sufferers, sex would seem to be a predisposing cause. But, as the disease is often very erratic in its attacks, sex cannot always be a determinate factor; nor is age.

Now, excluding cases in which the cause may be traced to some error of diet, intemperance in the use of food or drink, the loss of sleep, mental or physical strain, and to many other exciting causes the avoidance of which at once points out the proper remedy, we come to a type of the affection in which the peripheral nerves seem to play the main if not the sole cause in its induction. As nausea and vomiting are prominent symptoms of a certain order of brain disease, it is reasonable to infer, that the like symptoms, manifested in many attacks of migraine, attest a like sympathetic connection between the stomach and some functional disturbance of the brain

Remedial treatment of migraine thus becomes a treatment of its supposed cause, as well as for the relief of the distressing symptoms to which the disease owes its name. But, unfortunately, there are no known preventive means but what are tentative, provisional, and unconvincing. We are thus confined to the treatment of symptoms over which some remedies seem to exert more power than others. But, first, there are some adjunctive measures that even of themselves are capable of affording considerable relief.

At the outset, then, of an attack of migraine, or on the appearance of certain premonitory symptoms so well known to those suffering from sick headache, absolute rest and quiet should be en-joined, and, if possible (especially in the case of women), the sufferer should be kept in bed during the continuance of the attack, in a cool, airy room, somewhat darkened and remote from noise and society, and little or no nourishment be allowed except an occasional draught of water or a cup of a strong infusion of tea or of coffee, without milk or sugar. Tea and coffee sometimes alone give immediate relief. Applications to the head of cold, such as compresses kept constantly wet with cold water, and especially of ice in some manner, are valuable remedies. Sea baths have been advised with great benefit. But rest and quiet are, above all, to be insisted on, without which all the drugs in the pharmacopœia will be of no avail. Nature now, if at any time, requires absolute repose and the avoidance of all exciting causes.

Mental or psychic healing, as it is termed, has its advocates; and headache has not escaped its proportionate share of this form of treatment. beyond a few isolated examples of alleged cures of this affection by what has been denominated "suggestion," mental healing has never produced any permanent effect in times long past, and never will. It is a mere waste of time and money and but trifling with the weaknesses of human nature.

Much has been written on the subject of headache and many drugs prescribed for its relief. though no remedy has as yet been offered that possesses infallible curative properties. But, if specifics are unattainable, yet there are a few medicines which in a certain proportion of cases seem to exercise a remarkable control over this complaint, among which may be cited tea and coffee, already mentioned, though to a limited degree. But of all the drugs thus far known, Paullinia cupana, or

guarana, enjoys this peculiar property most conspicuously. At one time it was regarded as the true specific. In my hands it has been very satisfactory; in one instance particularly, that of a woman who had been a sufferer from headache for over thirty years. Under its use she became wholly exempt from attacks of it for the rest of her life, some fifteen or twenty years. Guarana should be administered in powders of twelve and a half grains each, every half or full hour until relief is obtained.

Of course it is the caffeine, contained in all three of these remedies, and of which guarana has the largest percentage, to which the benefit is to be ascribed. The dose of caffeine must, of necessity, be far smaller, but its method of administration

remains the same.

But the best form in which to administer this alkaloid, I find, is in conjunction with acetanilide and monobromated camphor, the camphor being added to counteract the depressing effects of the acetanilide, which is cumulative in its action; for its effects, like those of all the coal tar products, require constant watching. I use the pure alkaloid caffeine instead of any of its salts.

Potassium, sodium bromides, and other remedies are of pronounced value. Where there is considerable blood pressure or nervous excitement, the bromides have marked tranquillizing power in reducing the temperature and lowering the pulse.

Other adjuvants may be cited, such as the application of a stick of menthol to the aching spot or painting it with the tincture of aconite or with an appropriate solution of its alkaloid; and, lastly, the employment of anodynes and hypnotics, whose name is legion. An anæsthetic, if not too far continued, might be of service in attacks of exceptional severity. All drugs, however, of an uncertain or dangerous character should be scrupulously eschewed, and only those administered that experience has proved to be the safest and the most reliable.

Correspondence.

LETTER FROM LONDON

Burthden Honore.—Beauty Specialists."—Plague in Liverpool—Heredity and Disease—The Death of Sir Henry Pitman.

London, November 17, 1908.

In the honors list issued on the King's birthday medical men again figure prominently. First and foremost is the name of Sir Anderson Critchett, who becomes a baronet. He is a distinguished ophthalmic surgeon, and has been surgeon oculist to the King since 1901. His father, the late George Critchett, was also famous in this branch of surgery. Mr. Jonathan Hutchinson, Sen., F. R. S., F. R. C. S., has been made a knight. Though he is well known all over the world as one of the foremost syphilologists, his work in connection with the graphic representation of the lesions of disease and the scientific organization of museums deserves the widest acknowledgment by the medical profession. He was president of the Royal College of Surgeons of England in 1880-1800, and was recently congratulated by the Council of that body on the attainment of his eightieth birthday. Dr. Thomas Oliver

and Dr. Stewart Woodhouse have also received the honor of knighthood. Dr. Oliver is physician to the Royal Victoria Infirmary, Newcastle on Tyne, and has done a good deal of work in connection with trade diseases, in the investigation of which his experience has been very great and has frequently been turned to account by the government. Dr. Stewart Woodhouse, of Dublin, was formerly an inspector under the Local Government Board in Ireland and a member of the General Prisons Board of that country. Dr. Donald MacAlister has been made a Knight Commander of the Bath. Dr. MacAlister had a very brilliant career at Cambridge, being senior wrangler in 1877. He acted for a short time as mathematical master at Harrow, and was subsequently graduated M. D. at Cambridge. He was appointed physician to Addenbrooke's Hospital and delivered the Goulstonian lectures before the Royal College of Physicians in 1887. He became the representative of the University of Cambridge on the General Medical Council in 1889, and in 1904 was elected president in succession to Sir William Turner, K. C. B. In that capacity he has fulfilled his duties in a manner which has already insured his unanimous reelection to that office. He has also lately been elected principal and vice-chancellor of the Glasgow University.

In other branches of science appear the names of Dr. Alfred Russel Wallace, the veteran biologist, who has been appointed to the Order of Merit, and Professor J. J. Thompson, who has received the honor of knighthood, is Cavendish professor of physics in the University of Cambridge and presi-

dent elect of the British Association.

An interesting case came before the courts last week which has shed a flood of light on the mysterious arts of the "beauty doctor." A lady who had three small pits on the side of the nose as a result of smallpox was attracted by an advertisement setting forth the ability of the specialist to remove, among other things, smallpox pits from the face by "purely harmless and painless methods." She underwent the treatment. for which she paid a fee of thirty guineas. The result was disclosed in the court. According to the medical evidence, the treatment had resulted in a deep ulcer on the side of the nose, apparently caused by some caustic irritant. The jury awarded the plaintiff £500 damages, and found that Madame Auguste, otherwise known as Catherine Lavin, the beauty specialist, was guilty of fraud. One witness described how she was shown a woman patient at Madame Lavin's whose face on one side was wrinkled and on the other full and firm. The smooth side was kept continuously under plaster, except when it was necessary to show intending clients the results of the treatment, and then it was uncovered. Though this penalty will be a blow to the "beauty" trade, which is well established on Bond Street, it is doubtful whether it will stop their business or the folly of the public, who are ready to swallow all the nonsense of the printed pamphlets. The essence of this case is that unqualified persons are permitted to advertise themselves as ready to undertake treatment involving acts of a surgical nature and attended by the risks inherent to the unskilful performance of the simplest operations. It is an extraordinary fact that, in spite of the danger to society and the injury to orthodox

practitioners, the medical corporations, the General Medical Council, and the state do not appear to trouble themselves about the bogus "specialists" who abound in every large town in the United Kingdom. For all that, the verdict in this case will remain on permanent record as a warning to unlawful trespassers on the domain of a serious, highly technical, and responsible profession.

Two fatal cases of plague have recently occurred in Liverpool. One was that of a man who worked on a coaling barge, who fell ill suddenly and expired while being conveyed to the hospital. An inquest was held, and, as the cause of death was doubtful, the health authorities had a bacteriological examination carried out, with the result that the presence of the plague bacillus was established. A few days afterward two persons who had worked together with the deceased were found to be ailing and were at once removed to the hospital, where the disease was found to be plague. One of the patients died, but the other recovered. So far, there have been no fresh cases, and there is good reason to believe that no further spread of the disease need be apprehended. The most unsatisfactory feature of the case, however, is that no explanation of the origin of the first case is forthcoming, as the barge on which the patient was living does not go beyond the limits of the Mersey, and has only been engaged in coaling coasting vessels.

A special meeting of the fellows of the Royal Society of Medicine was held last week for the purpose of discussing the influence of heredity in disease, especially with regard to cancer, tuberculosis, and diseases of the nervous system. The debate was opened by Sir William Church, M. D., president of the society, who pointed out the importance of certain particular aspects of the subject under discussion-for example, the possibilities of a race prone to certain diseases eventually acquiring a natural protection against them. It was suggested that perhaps the gradual diminution of consumption in this country partly depended on the fact that after many centuries we were at last becoming protected by Nature against the ravages of this disease and that this protective quality in us was being handed down from one generation to the next and gaining power in the course of descent. In the study of heredity we require carefully recorded tables of family histories. And this is a field in which the general practitioner is in most cases more able to elicit facts than the specialist, who is not so familiar with the families of his patients.

Sir Henry Pitman, M. D., F. R. C. P., whose one hundredth birthday was recently celebrated, is dead. The deceased had a long connection with St. George's Hospital. He became assistant physician to the hospital in 1846, and eleven years later was elected full physician. He retired from the active staff in 1866, and since that time his name has figured on the list of consulting physicians. Altogether, therefore, he was connected with St. George's for sixty-two years as a member of the staff. He was one of the hospital physicians who helped to fight the terrible cholera outbreak of 1854. As registrar of the Royal College of Physicians Sir Henry filled another important public office for thirty-one years.

Therapentical Notes.

Untoward Effects Following the Use of Maraglianio's Serum.-Dr. H. R. N. Landis reports (The Therapeutic Gazette, November, 1908) untoward effects following the injection of Maraglianio's serum in seven cases out of forty-one treated with it. In six of these cases the patient's face became suffused within a minute or two after the administration of the remedy. An expression of great anxiety appeared, accompanied with difficulty in breathing; a feeling of oppression, particularly over the præcordium; the finger tips became blue, and the skin covered with a clammy sweat. The pulse rose to 140 and to 160 and became almost imperceptible after this. Nausea, vomiting, and intense pain in the lumbar region developed in three cases, while nausea and vomiting were provoked in one case. In all there was a feeling of impending death. In one case the patient screamed as the needle was withdrawn, became very pale, and muscular tremors developed. In all cases these effects passed off rapidly. In seven cases there was severe inflammation at the point of injection.

Application for Freckles.—Robin is credited in Journal de médecine de Paris for October 3, 1908, with the following formula for an application for

the removal of freckles:

taking care not to go beyond the spot.

The amount of corrosive sublimate should be varied according to the tenderness of the skin.

Tincture of Thuja for the Removal of Warts.—The local use of the tincture of thuja (arbor vitæ) for the removal of warts has been revived by several French physicians, as is shown by a communication in Clinique infantile for November 1, 1908. The tincture is made from the dried leaves of the plant by macerating one part of the leaves in five parts of eighty per cent. alcohol. Several drops of the tincture are injected beneath the skin and under the wart until the swelling of the part indicates the penetration of the liquid. Before injecting the tincture the part should be bathed for some time in hot water in order to soften the growth. After this treatment the wart turns a brownish black color, withers, and drops off.

The Treatment of Leucorrhea of Pregnancy.
—Siredey (La clinique, November 13, 1908) thus formulates the treatment of leucorrhea of pregnancy: Administer a vaginal injection of sterilized or lukewarm boiled water, to be followed by an injection of two pints of lukewarm boiled water containing two tablespoonfuls of dry yeast. Afterward introduce a tampon, attached by a thread, which has been soaked in a mixture of equal parts of yeast and boiled water; renew once a day. In place of the foregoing there may be injected twice daily boiled water containing a tablespoonful of Labarraque's solution, or a decoction of marshmallow root and poppy heads to each quart of which have been added, sodium bicarbonate, five drachms, and sodium chloride, two drachms.

NEW YORK, SATURDAY, DECEMBER 5, 1908.

THE IMMIGRATION SERVICE AT THE PORT OF NEW YORK.

We would invite particular attention to an article which we publish in this issue, entitled Cholera and Commerce, by Dr. William T. Jenkins. Dr. Jenkins's efficiency in protecting the city of New York from cholera some years ago, when he was the health officer of the port, will readily be recalled by many of our readers, and his experience with cholera entitles him to speak with a great measure of authority on that disease. But it is not altogether in the matter of cholera that Dr. Jenkins's article is of importance; incidentally he deals with certain other features of the quarantine service of the port and of the sanitary inspection of immigrants. The immense preponderance of New York over the other ports of the country, as vividly portrayed by Dr. Jenkins, renders the service at this port of exceedingly great importance.

Dr. Jenkins joins the great body of the medical profession in expressing appreciation of the excellence of the inspection of immigrants, but he recognizes, as we all do, that the resources at the command of the United States Public Health and Marine Hospital Service need to be considerably augmented to enable that service to do the best that its organization would enable it to do if those resources were adequately increased, especially in the matter of a sufficient number of officers. The simplest and most obvious solution of questions connected with the improvement of our national sanitary service certainly lies in strengthening the hands of the Public Health and Marine Hospital Service to the utmost, especially by enlarging the force of medical officers of the service and by increasing the

Detention hospitals are necessarily an important element in the administration of such an immigrant service as is required at the port of New York, so that persons arriving in a state calling for skilled observation and treatment have frequently to be sent to hospitals that are not under the immediate control of the national or State authorities. In those institutions, as Dr. Jenkins tells us, such persons are maintained at the expense of the steamship companies, and it therefore seems no more than fair, he thinks, that the companies' medical representatives should be accorded ample opportunities of observing the detained persons, if not some voice in their disposal pending their acceptance as immigrants or their deportation. It would also be only fair, we think, for the hospitals to make but a minimum charge to the companies.

PROFESSOR FALTA'S HARVEY LECTURE.

True to its principles, to give the medical practitioner not only the results of advanced scientific investigation, but also the practical application of this knowledge, the Harvey Society had for the subject of its lecture last week the treatment of diabetes, by the well known Viennese clinician, William Falta. In these days of scientific medicine it is well that an entire lecture should be devoted to the treatment of a disease. The modern tendency has been too much toward ætiological and pathological investigations, and while these are necessary foundations for a complete mastery of disease, they should on no account crowd out the careful study of treatment. After all, our patients care but little about their pathological condition; their interest lies solely in relief or cure of their symptoms.

In view of the complex nature of diabetes, a causal therapy is obviously out of the question. The symptomatic treatment concerns itself primarily with the chief symptom, the glycosuria. A little consideration will show that two possibilities of treatment present themselves, namely, either to increase the efficiency of carbohydrate metabolism or to diminish the requirement of this metabolism and give the diseased organs an opportunity to recover. The attempts made along the first of these lines included pancreatic transplantations and treatment with pancreatic extracts. These efforts, as is well known, were unsuccessful. In this connection it is well to remember that the sole cause of diabetes is not to be sought in the pancreas. It is possible that other organs elaborating an internal secretion are involved, and there is no doubt of the participation of the nervous system in some of the cases.

In combating the disturbance of carbohydrate metabolism, the main thing to attend to is the glycosuria. The question is sometimes asked, On what grounds de we seek to bring about the disappearance of the glycosuria? The answer to this is simple-in order to obtain for our patient the caloric value of the food he ingests. To take an extreme example, when a patient excretes daily 100 grammes of dextrose he loses 400 calories. Conditions may be such, however, that the mere substitution of fifty grammes of fat for the carbohydrate will make up this deficiency, and then our patient will be utilizing all his food supply. Furthermore, the glychæmia which goes with a true diabetes increases the disturbances of metabolism, thus establishing a vicious circle. It is important, therefore, not to be content with a reduction of the glycosuria to a few grammes of sugar per diem, but to insist on a complete suppression of the condition, including the hyperglychæmia. Each case must be studied by itself, and it is of the greatest importance to know exactly the character and extent of the disease. In Falta's clinic, each patient is placed for three days on a diet composed of 250 grammes of meat, 150 grammes of butter, four eggs, 300 grammes of vegetables, and 75 grammes of white bread, together with tea, bouillon, coffee, and light wine. This is divided into three equal meals for one day. The intake from such a food is calculated by Falta to be about six grammes of nitrogen and fifty grammes of carbohydrate. It furnishes about 2,400 calories.

The urine of these patients is carefully examined daily, and the total excretion of sugar noted. In this connection it is important to remember that the patients may also be excreting oxybutyric acid, and that therefore the polariscopic determinations may lead to erroneous conclusions regarding the amount of urinary sugar. Fehling's test, especially when the copper is added in excess and titrated back, is still the most reliable. However, a combination of both the polariscopic and Fehling determinations is often of decided value, for in that way one can obtain an indication of the amount of oxybutyric acid present. From a comparison of the intake and the excretion of sugar, one can learn what kind of a case one is dealing with. Instead of speaking of a negative carbohydrate balance, Falta prefers to take into account also the proteid metabolism, and cal-

The work of recent years has shown the impor-

tance of studying and treating the acidosis in diabetes. This is especially true during the period when the carbohydrates are being withdrawn. As a rule the condition can be controlled by the administration of alkalies, but there are cases in which the use of carbohydrates must be resumed. This was well brought out by the careful studies of Allard, working in Minkowski's clinic. When it is necessary to keep up the alkali treatment for some time, it is well to employ citrate of sodium. If the urine becomes and remains alkaline, one may be sure that the acidosis has been overcome.

The great danger from the acidosis, of course, is the production of diabetic coma. The onset of this condition is often marked by a feeling of drowsiness, lack of appetite, and a feeling of oppression in the chest. Frequently there is a decrease of the ketone bodies in the urine, and large quantities of casts are found. There is marked lipæmia, even during fasting. The one important thing to do is to administer alkalies as quickly as possible. carbonate of sodium, as much as 100 grammes daily, either in an alkaline mineral water or, better still, by means of intravenous infusions of a four per cent. saline solution. The diet should be easily digestible and contain some carbohydrate, preferably some lævulose. By this treatment it is possible to prevent an attack of coma, and even to overcome it after it has developed. It is to be noted, however, that there is no record of a second attack of diabetic coma from which the patient recovered.

Falta called attention to a small but interesting group of cases of diabetes in which there is marked disturbance of the pancreatic function. Some of these, for example, are associated with stone in the pancreatic duct. This condition leads to a marked interference with fat and proteid digestion, so that the stools of the patients are rich in fat and muscle fibres. In fact, occasionally the fat exudes from the anus and solidifies in a butterlike mass. All this time the patients are starving, are living on their own tissues. These patients can be saved by feeding them with pancreatic extracts and by keeping up the alkalinity of the intestines. In Vienna diabetic patients can obtain a highly porous gluten bread known as "Luftbrod." While this has not a great deal of nutritive value, it is an excellent vehicle for the administration of large quantities of butter and cheese. In this connection, we should like to direct the attention of our Pure Food Law officials to the deception practised by the manufacturers of a number of diabetic foods. While ostensibly made solely from gluten and other noncarbohydrate constituents, these flours, breads, etc., often contain considerable quantities of starch. Evidently

similar conditions exist abroad, for Professor Falta spoke of the misleading analyses often attached to these preparations. Perhaps our local Health Department can take hold of this matter.

THE FOOT AND MOUTH DISEASE.

The appearance of foot and mouth disease among the cattle of Pennsylvania has led to the publication in the sensational press of exaggerated statements as to the danger of infection of human beings. It is true that the disease may be contracted by man, but the number of cases which have occurred in the United States has never been large even where the disease has been widespread among cattle. In man it is generally restricted to children who drink large quantities of unboiled milk and to adults who handle animals infected with the disease. The disease prevails much more extensively among the cattle of Europe than among those of the United States, and it is believed by some veterinarians that where the disease is prevalent among animals it frequently occurs in human subjects without being recognized by the physician. The disease is rarely fatal, though it causes great losses from the diminution of the milk secretion and the consequent interference with the business of the dairy. Wherever the disease has appeared in America it has heretofore been quickly suppressed by a most rigid quarantine and the destruction of the infected herds.

The characteristic symptoms of foot and mouth disease (aphthous fever) are a combination of high fever, vesicular inflammation of the mouth, and a hot, painful, swollen condition of the feet, followed in from twenty-four to forty-eight hours by the appearance of numerous small vesicles varying in size from that of a pea to that of a hazel nut on the udder and feet and in the month. No other disease of cattle produces symptoms likely to be confounded with these. The disease makes its appearance in from three to six days after exposure to infection, the first symptom noted being a chill rapidly followed by a fever producing a temperature sometimes as high as 106° F. After a day or two small vesicles appear on the mucous membrane of the mouth, at the border and on the upper surface of the tongue, on the inner side of the cheeks, and on the inner surface of the lips. These vesicles contain a yellowish watery fluid and gradually grow until they reach a diameter of from half an inch to an inch and a half. The vesicles break after a day or so and a grayish white membrane is formed which disappears, leaving a reddened, sensitive spot or erosion in the mouth and on the coronet and between the claws of the feet. The fatal cases are those in which the internal organs are attacked before the disease appears on the external parts.

Where death occurs it seems to be due to paralysis of the heart caused by the toxines produced by the disease.

So far, no specific bacillus has been isolated, though the disease is generally believed to be of microbial origin. The Bnreau of Animal Industry of the United States Department of Agriculture has recently issued a circular on this disease from which the data given above are taken. The authors, Dr. D. E. Salmon and Dr. Theobald Smith, say that relief may be obtained by treating the symptoms. Local applications, disinfecting and astringent lotions, may be used to combat the local symptoms. In weakness of the heart digitalis, camphor, and alcohol may be administered, and excessive fever may be reduced by the use of phenacetin.

THE ARMY MEDICAL RESERVE CORPS.

The regular Army Medical Corps and the medical profession in general throughout the country undoubtedly feel that the new Medical Reserve Corps will relieve the medical service of the army of much embarrassment in case of the outbreak of another war. The reasons for this feeling have been fully stated in print more than once, and no dissent has been evoked from professional sources, so far as we have observed. But the New York Times is of a different opinion. It fears that the appointees on the new corps will prove incompetent, and calls them "a lot of civilian doctors." The truth is that the great majority of the newly commissioned officers are men of military experience, acquired in the civil war, in the war with Spain, in the Philippine operations, and in militia camps and marches. Surely such a body of men is to be preferred to those appointed in haste by the governors of States

NEWSPAPER PHYSIOLOGY.

A correspondent recently asked the New York Times the following question: "Which is the quicker, the hand or the eye? Can the difference be reduced to a question of time?" We do not see how it could be anything else than a question of time, but let that pass. The paper replies that the trained hand is much quicker than the eye, and it adds this remarkable statement in support of its decision: "The act of perceiving and identifying an object-a letter of the alphabet, for example-requires about two hundredths of a second, the experts tell us. The trained prestidigitator can accomplish a definite movement of the hands, like the juggling of a card, in about fifteen hundredths of a second." To those of us who are not "experts" the Times's reply seems to carry its own refutation.

Obituary.

ANDREW J. McCOSH, M. D., of New York.

In the fifty-first year of his age, at the height of his usefulness, Dr. McCosh has succumbed to an injury of the head caused by his being thrown from his carriage in a runaway accident. He was taken to the Presbyterian Hospital, of which he was one of the surgeons, and died on Wednesday, December 2d, without having regained consciousness. Dr. McCosh was a native of Belfast, Ireland, but virtually his entire life was spent in this community. He was a graduate of the College of Physicians and Surgeons, of the class of 1880. Soon after his graduation he achieved prominence as a surgeon, and for the last twenty years of his life he was a hospital surgeon and active in private practice. He was recognized by the profession in general as a surgeon of exceptional ability, and he was respected accordingly; moreover, his attractive personal qualities caused him to be loved by everybody who knew him.

Hews Items.

The Boston Society of the Medical Sciences recently elected the following officers: Professor W. B. Cannon, president; Dr. J. L. Bremer, secretary; Professor F. B. Mallorv, treasurer.

An English-Chinese Lexicon of Medical Terms, prepared by Dr. Philip B. Cousland, has just been published in Shanghai. Dr. Cousland has recently published a translation of Halliburton's edition of Kirkes's Physiology.

Changes of Address.—Dr. H. Austin Cossitt, from Morris Plains, N. J., to 146 West 70th Street, New York. Dr. M. Barbour to 1619 South Sixth Street, Philadelphia. Dr. Frederick Krauss, to the Roger Williams Building, 1701 Chestnut Street, Philadelphia.

The H. K. Cushing Laboratory of Experimental Medicine, at the Western Reserve University, Cleveland, Ohio, was dedicated on November 20th. Dr. William H. Welch, of the Johns Hopkins Medical School, made the principal address. Dr. George N. Stewart is director of the laboratory.

The Harvey Society Lectures.—The fifth lecture in the Harvey Society course will be delivered by Dr. M. J. Rosenau and Dr. John F. Anderson, of the United States Public Health and Marine Hospital Service, on Saturday, December 5th, at 8:30 p. m., at the New York Academy of Medicine. The subject will be Anaphylaxis.

Contagious Diseases in Chicago.—Seven hundred and eighty-eight cases of contagious diseases were reported to the Department of Health during the week ending November 21, 1008. Of these 214 were of diphtheria, 212 of scarlet fever, 58 of measles, 68 of chickenpox, 42 of typhoid fever, 25 of pneumonia, 17 of whooping cough, 127 of tuberculosis, and 24 of minor diseases.

The Rochester, N. Y., Academy of Medicine.—The regular monthly meeting of Section I, which includes general medicine, neurology, psychiatry, materia medica, and therapeutics, was held on Friday evening, December 4th. Dr. Henry L. Elsner, of Syracuse, N. Y., read the paper of the evening on the Comparative Values of the Tuberculin Tests, with Special Consideration of the Ophthalmic.

Amalgamation of Medical Societies.—A union of the Southeastern Medical Society and the Eastern Medical Society, of Philadelphia, has been effected. The new society will be called the Southwark Medical Society, and will meet the first and third Thursdays of each month. The following officers have been elected: Dr. M. Staller, president; Dr. A. Brav, vice-president; Dr. M. B. Cooperman, secretary; and Dr. J. J. Frankel, treasurer.

The American Society of Sanitary and Moral Prophyalaxis.—A regular meeting of this society will be held at the New York Academy of Medicine, on Thursday evening, December 10th. The subject for consideration will be The Lecture Work of this Society. Papers will be presented by Dr. Thomas M. Balliet, dean of the School of Pedagogy, Professor F. N. Seerley, Dr. Emma E. Walker, and others. A general discussion will follow.

The Obstetrical Society of Philadelphia.—At a stated meeting of this society, held on Thursday evening, December 3d, Dr. Henry D. Fry, professor of obstetrics in the Medical Department of Georgetown University, read a paper entitled The Best Methods of Terminating the First Stage of Labor, with Special Reference to Vaginal Cæsarean Section. Dr. Barton Cooke Hirst, Dr. E. P. Davis, Dr. Alice Weld Tallant, Dr. R. C. Norris, and Dr. G. M. Boyd took part in the discussion.

The Elmira, N. Y., Academy of Medicine.—The regular meeting of this academy was held on Wednesday evening, December 2d. The programme included papers as follows: The Extent, Diagnosis, and Prevention of Rabies, by Dr. Veranus A. Moore, of Cornell University, Ithaca, N. Y.; Some Observations upon Japanese Sanitation, by Dr. F. W. Ross, of Elmira, N. Y.; Syphilis of the Nervous System and its Treatment, by Dr. Floyd S. Crego, of Buffalo, N. Y.

Syracuse, N. Y., Academy of Medicine.—A meeting of this academy was held on Tuesday evening, November 24th. The programme included the following papers: Long Continued Infection in a Case of Appendicitis, by Dr. C. F. Wiley; The Diet in Typhoid Fever, by Dr. I. H. Levy; Report of a Case of Cæsarean Section for Contracted Pelvis, with Demonstration of Apparatus for Measurement of Pelvis by the X Ray, by Dr. A. S. Hotaling and Dr. C. E. Coon.

Epidemics in Pennsylvania Cities and Towns.—Reading, Pa., is experiencing a rather severe epidemic of typhoid fever. Allentown has scarlet fever and diphtheria in epidemic proportions. Lehigh County has an epidemic of foot and mouth disease among the cattle, which has extended to other counties and has made its presence known in Philadelphia. There is much anxiety on the part of some that the disease might affect the human population of the infected areas. The cases of human infection with foot and mouth disease are rare in the United States.

The Buffalo, N. Y., Academy of Medicine.—The regular meeting of the Section in Surgery of this academy was held on Tuesday evening, December 1st. The programme consisted of a "symposium" on Fractures. Papers were read as follows: The Use of the X Ray in Fractures, by Dr. W. W. Plummer; The Nonoperative Treatment of Fractures, by Dr. Frank J. Carr; The Operative Treatment of Fractures, by Dr. Marshall Clinton; Complications in the Treatment of Fractures, by Dr. Roswell Park. Among those who took part in the discussion were Dr. Eugene A. Smith and Dr. Edgar R. McGuire.

The Section in Medical History of the College of Physicians of Philadelphia held a stated meeting on Monday evening, November 30th. Dr. W. W. Keen read a paper entitled Remarks on the Incumabula and Other Books Purchased for the College during My Stay in Europe, and also on the Sepulchral Mural Tablets of Bologna. The paper was accompanied by an exhibition of incumabula and photographs of mural tablets. Dr. Charles W. Burr read a paper on the Life of Jerome Cardan. Dr. James J. Walsh, professor of the history of medicine at Fordham University, New York, read a paper on Old Time Medicine and Medical Education.

The Medical Association of the Greater City of New York.—A special meeting of this association, under the direction of the Chairman for the Borough of the Bronx, will be held on Monday, December 7th, at 8:30 p. m., at the residence of the chairman, Dr. N. B. Van Etten, Tremont Avenue, corner of Anthony Avenue, New York. Papers will be read as follows: Conclusions in regard to the Best Surgical Treatment in Tic Douloureux, by Dr. Robert Abbe; The Common Forms of Gastroenteric Neuroses: Their Ætiology and Treatment, by Dr. Anthony Bassler; Some Drugs for Gyngecological Patients, by Herman J. Boldt. Among those who will participate in the discussion are Dr. Jacob Kaufmann, Dr. Ludwig Kast, and Dr. William II. Porter.

Cholera in St. Petersburg.—It is reported that Asiatic cholera has broken out again in St. Petersburg. It was thought that the disease which was epidemic in the city about three months ago, had been practically eradicated, but new cases are being reported every day.

The Rockefeller Institute for Medical Research.-At a recent meeting of the board of directors of this institution, Dr. Rufus I. Cole, of the Johns Hopkins Medical School, Baltimore, was appointed director of the hospital, and Dr. Christian A. Herter was appointed one of the physicians. Work on the hospital buildings is in progress, and it is exceeded the tables. pected that they will be completed and ready for occupancy in November, 1909.

The Health of Pittsburgh.- During the week ending November 21, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickendiseases were reported to the bureau of realit. Chicken-pox, 21 cases, 0 deaths; typhoid fever, 16 cases, 1 death; scarlet fever, 43 cases, 2 deaths; diphtheria, 29 cases, 3 deaths; measles, 23 cases, 0 deaths; whooping cough, 4 cases, o deaths; pulmonary tuberculosis, 31 cases, 10 deaths. The total deaths for the week numbered 143, in an estimated population of 565,000, corresponding to an annual death rate of 13.16 in 1.000 population.

Charitable Bequests.—By the will of Franklin W. Russell, of Pittsfield, Mass., the House of Mercy, Pittsfield, receives \$25,000; the Pittsfield Hospital receives \$1,000 for the maintenance of a room, to be known as the S. N. Russell room; the Boys' Club of Pittsfield receives \$25,000; the Pittsfield Y. M. C. A. receives \$25,000; Baker Memorial Church receives \$7,000; and the Graduate Nurses' Association receives \$5,000.

By the will of William Ulmer, of Brooklyn, the German

Hospital, at St. Nicholas Avenue and Stanhope Street, re-

ceives \$10,000.

The Hospital Ship Relief.—The Navy Department received a cable despatch on November 25th from Surgeon Stokes, who is in command of the Hospital ship Relief, stating that the ship had arrived safely at Sorsogon, Philippine Islands. While on the voyage from Manila to Guam the ship was struck by a typhoon on November 18th and was badly damaged. At the same time fire broke out in the ship, which the crew succeeded in putting out. porary repairs to the ship's engines were made by the crew, so that she proceeded under her own steam to Manila by way of Southern Luzon.

Infectious Disease in New York:

We are indebted to the Bureau of Records of the De-zarment of Health for the volumes, statistics of new cases and deaths reported to be the needs ending No-

Scientific Society Meetings in Philadelphia for the Week Ending December 12, 1908:

Monday, December 7th.—Philadelphia Academy of Surgery: Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society, Wills Hospital Ophthalmic Society.

TUESDAY, December 8th .- Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences

THURSDAY, December 10th .- Pathological Society; Section Meeting, Franklin Institute.

FRIDAY, December 11th .- Northern Medical Association; West Branch, Philadelphia County Medical Society.

Vital Statistics of New York .- During the week ending November 21, 1908, there were reported to the Department of Health of the City of New York 1,236 deaths from all causes, as compared with 1,207 for the preceding week,

and 1,322 for the corresponding period in 1907. The annual death rate in 1,000 of population was 14.58 for the week, 15.81 for the preceding week, and 16.09 for the corresponding period in 1907. The death rate for the week in responding period in 1907. The death rate for the week in Manhattan was 14.90; in the Bronx, 19.27; in Brooklyn, 13.38; in Queens, 13.01; and in Richmond, 12.93. Of the total number of deaths 323 were of children under five years of age, and of these 223 were less than one year of age. There were 14 deaths from suicide, 3 deaths from homicide, and 65 deaths from accidents. One hundred and forty still births were reported. There were 605 marriages and a 366 births during the week and 2,362 births during the week.

The Tuberculosis Camp on the Roof of the Vanderbilt Clinic, Sixtieth Street and Amsterdam Avenue, was formally opened on Saturday, November 28th. At present this is a day camp for tuberculosis patients, but as soon as the necessary arrangements can be made, it will be opened for patients at night. It has the appearance of a roof garden, is 160 feet above the street, and overlooks the river. It is open to the south, the other three sides being inclosed with pivoted windows. The camp is open from 9 a. m. to with pivoted windows. The camp is open from a first property of p. m., and doctors and nurses are in constant attendance. It is free to persons living north of Fiftieth Street, west of Eighth Avenue, and south of Spuyten Duyvil. The Red Cross Society has volunteered to support it for the first year, but an endowment of at least \$100,000 will be needed to make it a permanent establishment.

The Mortality of Chicago.-During the week ending November 21, 1908, there were reported to the Department of Health of the City of Chicago 596 deaths from all of Health of the City of Chicago 590 deaths from an 535 for the corresponding period in 1907. The annual death rate in 1,000 population was 14,34, as against a death rate of 13,24 for the corresponding period last year. Of the total number of deaths 111 were of children under one year of age, and 52 were of children between one and five years. The principal causes of death were: Apoplexy, deaths: Bright's disease, 50 deaths: bronchitis, 25 deaths; consumption, 77 deaths; cancer, 29 deaths; diphtheria, 23 deaths; heart disease, 50 deaths; influenza, I death; intesdeaths, heart diseases, 50 deaths; measles, 6 deaths; nervous diseases, 9 deaths; pneumonia, 63 deaths; scarlet fever. 13 deaths; suicide. 8 deaths; typhoid fever, 5 deaths; violence, other than suicide, 30 deaths; all other causes, 138 deaths.

New York Academy of Medicine .-- A meeting of the Section in Padiatrics will be held on Thursday evening, December 10th, at 8:15 o'clock. Dr. E. A. Riesenfeld will cember 10th, at 8:15 o'clock. Dr. E. A. Riesenfeld will present x ray pictures of a case of infantile scurvy. Dr. Herman Schwarz will report a case of hæmorrhage in the newborn, apparently due to delayed coagulability of the blood. Dr. William H. Stowell will read a paper entitled Infant Mortality; A Comparison of the Past and Present. Dr. William H. Guilfoy, Dr. John Spargo, Dr. Abram Brothers, and Dr. W. C. Phillips will take part in the dis-

The Section in Otology will meet on Friday evening, December 11th, at 8:15 o'clock. Dr. Seymour Oppenheimer will present a patient with mastoiditis, sinus thrombosis, extradural abscess, and meningitis. Dr. Frank T. Hopkins will exhibit a specimen of sequestrum of labyrinth. Dr. Emil Gruening will read a paper on Sinus Thrombosis and Streptococcæmia. There will be a general discussion

The Philadelphia Neurological Society.-At the regular meeting of this society, which was held on Friday evening, November 27th, the programme included the presentation of the following cases: Intermittent Claudication, by Dr. M. D. Bloomfield; Cerebellar Syndrome showing Dr. M. D. Bloomfield; Cerebellar Syndrome showing Progressive Improvement after a Decompressive Operation, Progressive Improvement after a Decompressive Operation, by Dr. Alfred Gordon; Facial Spasm treated by Alcoholic Injection, by Dr. William G. Spiller; Symptoms of Bilateral Motor Tract Disease with Dissociation Anaesthesia, by Dr. J. W. McConnell; The Symptom Complex of a Lesion of the Upper Part of the Anterior Spinal Arteries, by Dr. Charles K. Mills. Papers were read as follows: A New Symptom Complex, Flaccid Paralysis or Extreme Hypotonia of the Muscles which Poise and Support the Head, by Dr. Charles K. Mills; The Duration of Life after Extensive Hæmorrhage of the Brain, by Dr. William G. Spiller; The Uses of High Frequency Currents in Neurol-Spiller; The Uses of High Frequency Currents in Neurology, by Dr. William J. Dugan; Sacral Tabes, by Dr. S. Leopold; A case of Supernumerary First Rib, by Dr. T. A.

The Medical Society of the County of Otsego, N. Y .--The one hundred and second annual meeting of this society will be held in the County Court rooms, Oneonta, N. Y., on Tuesday, December 8th. At the first session, which will begin at 10:45 a. m., reports from officers, delegates, and committees will be received, officers for the ensuing year, new members, and delegates will be elected, and all other routine business will be transacted. The afternoon session will begin at 1:30 o'clock. An interesting programme has been prepared, which includes the following papers: Obituary of Dr. Charles E. Parrish, by Dr. Arthur W. Cutler; Rare Surgical Operations, by Dr. Henry W. Boorn; A Successful Treatment for Some Obstinate Forms of Skin Diseases, by Dr. Delos B. Manchester; Ether Gas Anæsthesia, by Dr. Charles R. Marsh. The discussion on these papers will be opened by Dr. Henry D. Sill, Dr. Joshua J. Sweet, and Dr. Willis S. Cook. Dr. Arthur H. Brownell, of Oneonta, is acting president of the society, Dr. Henry W. Boorn, of Schenevus, is secretary, and Dr. Frank L. Winson, of Laurens, is treasurer. been prepared, which includes the following papers: Obitsor, of Laurens, is treasurer.

Society Meetings for the Coming Week:

Monday, December 7th.—German Medical Society of the City of New York; Utica, N. Y., Medical Library As-sociation; Niagara Falls, N. Y., Academy of Medicine; Practitioners' Club, Newark, N. J.; Hartford, Conn.,

TUESDAY, December 8th.—New York Academy of Medicine (Section in Public Health); Medical Society of the County of Schenectady, N. Y.; Practitioners' Club of Jersey City. N. J.; Medical Society of the County of Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

Wednesday, December oth.—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of the Bronx, Alumni Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Medical Society of the County of Richmond, N. Y

THURSDAY, December 10th.-New York Academy of Medicine (Section in Paediatrics); Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers,

FRIDAY, December 11th.-New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York (annual); Saratoga Springs, N. Y., Medical Society; New York Academy of Medicine (Section in Otology).

SATURDAY, December 12th.-Therapeutic Club, New York.

The International Tuberculosis Exhibit.—The tuberculosis exhibit, which was shown at Washington, D. C., in connection with the Sixth International Congress on Tuberculosis, is now on exhibition at the American Museum of Natural History, Seventy-ninth Street and Columbus Avenue, New York. The cost of bringing this great exhibit to New York was met by an appropriation of \$13,000 by the city and by an additional fund raised by the Committee on Tuberculosis of the New York Charity Organization Society. To make the exhibits readily understood, full descriptions and explanations are furnished by trained men and women. The exhibition is open daily from 10 a. m. to 11 p. m., and on Sundays from 1 to 5 p. m. No tickets are required. Arrangements have been made for a number of public meetings to be held in connection with the exhibit, and there will also be a number of special conferences for and there will also be a number of special conferences on the medical profession, the churches, the Y. M. C. A., labor unions, etc. At the first medical conference, which was held on Friday evening. December 4th, addresses were made by Dr. Lawrence F. Flick, Dr. Simon Flexner, Dr. Joseph D. Bryant, and Mr. Edward T. Devine. On Monday, December 8th, at 4:30 p. m., there will be a mass meeting of medical students, and among the speakers at this meeting will be Dr. G. F. Laidlaw, Dr. H. M. Biggs, Dr. W. B. James, Dr Woods Hutchinson, Dr. W. Gilman Thompson, Dr. John B. Huber, and Dr. S. Adolphus Knopf. On December 11th a special medical meeting will be held under the auspices of the Section in Public Health of the New York Academy of Medicine, at which Dr. John A. Wyeth will preside, and Dr. Walter F. Wilcox will deliver an address. 1 1 . 1. 1.1 under the auspices of the Homocopathic Medical Society of the County of New York. Dr. George F, Laidlaw will pre-

side, and among the speakers will be Dr. Thomas Darlington, the Hon. Robert Hebberd, the Hon. Eugene H. Porter. and Dr. H. D. Pease.

The Hayden Medal, awarded at irregular intervals by the Academy of Natural Sciences of Philadelphia, was awarded this year to Mr. John Mason Clarke, State Geologist of New York, for his work on geology, his best known works being The Early Devonic History of New York and Eastern North America. The medal, which was formerly of bronze, was awarded every year from the foundation of the fund until 1899. In that year it was decided to award the medal every three years and to offer a gold medal instead of the bronze one originally given. The following awards have been made since the establishment of the fund awards have been made since the establishment of the fund by Mrs. Emma W. Hayden in honor of her husband, Dr. Ferdinand V. Hayden: 1890, James Hull, State Geologist of New York; 1891, Edward D. Cope, of Philadelphia, distinguished paleontologist; 1892, Edward Suess, of Vienna, author of Das Antlitz der Erde; 1893, Thomas H. Huxley, of London, the distinguished biologist and paleontologist; 1894, Gabriel Auguste Daubree, of the Institute of France; 1895, Karl A. von Zittel, of Munich, author of the Monumental Handbuch der Paleontologie; 1896. Golovani Capellini of Bologna president of the Royal Geological Survey. mental Handbuch der Paleontologie; 1896. Giovanni Capelini, of Bologna, president of the Royal Geological Survey of Italy; 1897, A. Karpinski, of St. Petersburg. director of the Geological Survey, of Russia; 1898, Otto Maryin Torell, Chief of the Geological Survey, of Sweden; 1899, Gilles J. G. Duvalque, Secretary of the Geological Society of Belgium; 1902, Archibald Geikie, Director of the Geological Survey of Great Britain; 1905, Charles Doolittle Walcot, Director of the United States Geological Survey and now Secretary of the Smithsonian Institution.

Appointments in the Army Medical Reserve Corps .-Announcement is made of the following appointments as first lieutenants in the medical reserve corps of the United

States Army:
Baltimore: Dr. J. C. Bloodgood, Dr. Harvey Cushing,
Dr. Alexander C. Abbott. Dr. J. M. T. Finney, Dr. William
S. Thayer, Dr. W. T. Halsted.
Woodstock, Vt.: Dr. C. W. Sherwin.
Washington, D. C.: Dr. H. C. Yarrow, Dr. J. F. Mitchell.

Dr. C. W. Richardson.
San Francisco, Cal.: Dr. W. S. Thorne, Dr. T. W. Huntington, Dr. H. M. Sherman. Dr. H. C. Moffitt, Dr. W. I. Terry, Dr. J. W. Shiels, Dr. B. F. Alden, Dr. A. J. Houston, Dr. W. F. Cheney, Dr. C. G. Levison, Dr. Emil O. Jellinek.

New Orleans, La.: Dr. E. Souchon, Dr. L. F. Reynaud, Dr. J. J. Archinard, Dr. Isadore Dyer, Dr. Rudolf Matas. Detroit, Mich.: Dr. H. O. Walker, Dr. J. H. Carstens,

Dr. Angus McLean. New York: Dr. Carl Beck. Dr. W. G. Thompson, Dr. R. New York: Dr. Carl Beck. Dr. W. G. Hondison, Dr. R. T. Morris, Dr. A. J. McCosh, Dr. Thomas Darlington, Dr. S. T. Armstrong, Dr. Alexander Lambert, Dr. W. H. Haskin, Dr. L. A. Conner, Dr. David Stewart, Dr. Simon Flexner, Dr. Samuel Lloyd, Dr. Robert F. Weir, Dr. F. P. Foster, Dr. Joseph D. Bryant, Dr. John A. Wyeth, Dr. F. P. Kinnicutt, Dr. Alexander Smith, Dr. V. P. Gibuey, Dr. W. T. Bull, Dr. F. S. Dennis, Dr. A. H. Doty, Dr. Robert

Abbe.
Philadelphia: Dr. J. H. Musser, Dr. G. E. de Schweinitz, Dr. Edward Martin, Dr. B. C. Hirst, Dr. C. S. Penrose, Dr. H. A. Hare, Dr. J. C. Da Costa, Dr. R. G. Leçonte, Dr. James C. Wilson, Dr. J. William White, Dr. Richard H. Harte, Dr. J. G. Clark, Dr. A. Stengel, Dr. D. L. Edsall, Dr. C. H. Frazier, Dr. J. H. Gibbon, Dr. William Pepper, Dr. F. D. Patterson, Chicago: Dr. C. S. Bacon, Dr. J. B. Murphy, Dr. H. B. Favrill, Dr. A. D. Bevan, Dr. M. L. Harris, Dr. George H. Simmons, Dr. Frank Billings, Dr. W. E. Schneider, Dr. A. J. Ochsner, Dr. A. E. Halstead, Dr. C. L. Mix. St. Louis: Dr. H. G. Mudd. Boston: Dr. J. C. Munro, Dr. Theobald Smith, Dr. C. L. Scudder, Dr. J. C. Munford, Dr. F. G. Balch, Dr. J. B. Blake, Dr. R. H. Fitz, Dr. F. C. Shattnek, Dr. Myles Standish, Dr. W. T. Councilman, Dr. S. T. Miyter, Dr. William H. Conant, Dr. Farrar Cobb, Dr. R. C. Cabot, Dr. J. T. Bottomley, Dr. F. A. Washburn, Dr. W. C. Howe, Dr. D. Cheever.

Cleveland, Ohio: Dr. George W. Crile. Ann Arbor, Mich.: Dr. C. B. G. Denanerode, Dr. V. C.

Revelworth, Ill.: Dr. Sanger Brown. Buffalo, N. Y.: Dr. Roswell Park.

1. The Relation between Human and Animal Tuberculosis.—Smith reviews the opinions on the question whether it is possible that bovine tubercle bacilli may assume the human type in man, and that human bacilli may become bovine in cattle. He comes to the conclusion that the time has not yet come for us to state positively that one type can or cannot be transformed into the other. The very nature of the methods employed leaves a big gate for errors to sneak in, and the proof if it ultimately comes will be more in the nature of a majority vote than a demonstration. In the meantime we may safely take the ground that any regular or wholesale conversion of bovine into human bacilli in the human body is out of the question, as contradicted by most of the experimental evidence thus far presented and by certain observations made on the occurrence of the spontaneous disease. We know that human tuberculosis can exist without the aid of bovine tuberculosis, and an important aid in the final solution of this question will be the study of human tuberculosis in such regions where the bovine disease does not exist, and where the dairy products are not shipped in from countries in which the disease prevails. The difference between the human and bovine types pertains to morphological, cultural, and pathogenic characters. On serum the human type is longer and slenderer than the bovine type and slightly curved. It grows readily from the start, often profusely, and after the first generation multiplies freely on glycerin agar and glycerin bouillon, forming on the latter a thick, nodular, or puckered membrane. The colonies on serum are in the characteristic S shaped bundles first described by Koch. The bacilli in the bovine colonies are grouped irregularly without any distinct conglutination into bun-After the bovine bacillus has vegetated for several generations on egg or serum it will begin to grow feebly on glycerin agar and bouillon, where it forms a very delicate membrane, suggesting tissue paper, with occasional thickenings in it. After a fairly vigorous growth has established itself on glycerin bouillon, the bovine type presents the peculiarity of converting a bouillon, containing five per cent. glycerin and of a certain degree of acidity to phenolphthalein, into an alkaline medium. The human type does not do this. At the end of one to two months the bovine type is alkaline, the human type acid. The acidity of some types reaches four per cent. of a normal solution; that of other types but 1.5 per cent. to 2 per cent. The bovine bacillus is highly pathogenic for rabbits and cattle; the human type is not. Though the bovine bacillus slowly degenerates in virulence with prolonged cultivation, yet its virulence for these species is remarkably tenacious.

3. Ophthalmology for General Practitioners. -Connor remarks that general practice ophthalmology is all of ophthalmology the student can master without violence to other courses, and a family physician can practise in harmony with his work. includes four factors: The ability to recognize and treat eye injuries (except foreign bodies within the eyeball); the recognition and treatment of all eve infections and diseases of the uveal tract; the recognition and management of simple presbyopia, simple myopia, and simple hyperopia. The best interests of the profession and laity demand a mastery of general practice ophthalmology by every physician. The medical college obstacles to this can be removed (1) by eliminating from every course all chaff; (2) by adjusting the proportion of courses to the actual needs of the family physician, and (3) by insisting that all the professors be trained in the art of pedagogy, as well as the art of medicine. The machinery of State medical societies and the American Medical Association should be used to awaken the interest of licensed physicians and induce registration boards and medical colleges to place among their requirements a "general practice ophthalmol-

5. Abnormal Secretion from the Mammary Glands in the Nonpregnant.—Gellhorn says that the physiological, that is, the most common, and at the same time the strongest, stimulus for the function of the mammary gland is pregnancy. As a rule, the formation of colostrum begins in the second month of gestation, the transformation into milk on the second or third day of the puerperium. The period of lactation lasts, on an average, one year, but ranges, in individual cases, within wide limits. It is, however, permissible to speak again of abnormal mammary secretion in nonpregnant women if the duration of lactation exceeds two years, when the organism of the child obviously has become independent of the milk supply from the mother. Yet it is an altogether common occurrence to see lactation intentionally prolonged for an indefinite period of time. The clinicians have been always inclined to assume an influence of the nervous system on lacteal secretion, and they have based their views mainly on the observation that the secretion of milk is some-

times greatly altered by such emotions as passion, grief, or mental depressions. The textbooks on physiology arrive at similar conclusions, principally from analogy between the mammæ and other glands, the secretion of which is subject to nerve stimuli. According to Halban the ætiology of mammary functions has nothing to do with the fœtus, but this function is due to the internal secretion of the ovary; in pregnancy the function of the ovary is temporarily assumed by the internal secretion of the placenta. This theory throws much light on a problem of science which hitherto has been very obscure, despite the enormous number of investigations which have preceded our author's. H. de Rothschild has collected up to 1899 not less than 8,375 publications on this subject. Lacteal secretion does not only occur in pregnancy and puerperium but it also may appear in the newborn, in the growing child, in the adult virgin, and in the old woman. It may be prolonged indefinitely after childbirth, and may be associated with certain pathological conditions within the genital sphere. Aside from the intense scientific interest in the ætiology of lacteal secretion, there is also considerable practical importance attached to abnormal activity of the mammary glands, and a thorough knowledge of a typical function of these organs is indispensable to the expert in medicolegal practice.

7. The Diuretic Action of Adrenalin and the Active Principle of the Pituitary Body.-Houghton and Merrill have made experiments on this subject. They find that the explanation of the increased urinary flow in anæsthetized animals depends chiefly on the increase in blood pressure produced by the intravenous injection of the adrenalin solution or the pituitary extract in solution rather than on a specific action on the secreting cells of the kidney. It is possible, however, that a specific action on the kidneys occurs, but if so it is less marked than in the case of the one per cent. saline solution. Microscopical observation of the perfused kidney indicated that there was considerable enlargement of the organ while the experiments were being carried out. This would assist in the more rapid secretion of urine, especially if accompanied by increased pressure, but, as just stated, there is not the same degree of relaxation or dilatation of the blood vessels in the kidney as follows the perfusion with the saline itself. This is as we would expect, since experiments on the web of the frog, on the inflamed conjunctiva of the rabbit, and other animals show positively that the pituitary extract does narrow the caliber of the arterioles. If the pituitary extract possesses, as Shafer believes, the specific secretory effect, it would seem that it should manifest itself by greatly increased flow of urine when brought in contact with the secretory cells of the kidney. If it does have this pecific action it has it to a much less degree than sodium chloride itself.

8. The Treatment of Tuberculosis by the Administration of Mercury.-Wright adds interestine data to his former paper (United States Naval Medica' Bulletin, April, and New York Medical Journal, August 29, 1908). He believes that mercurv acts in two ways: First, as a tonic, increasing the vitality of the cellular elements of the various organs and tissues, and, second, in rendering the blood bactericidal, producing an antitor inc therein.

which has a direct destructive action on the tubercle bacillus. This action of mercury is cumulative and lasting, and the immunity conferred by the early doses, plus the resistance to the disease developed by the increased cellular vitality, places the patient in such condition that as treatment is continued smaller doses of mercury are required to obtain the desired results. If we continue to give the improving patient the same dose of mercury on which he was first placed and began to improve we shall sooner or later notice, first, a rise in temperature, and, second, a loss of weight. Should these signs be passed unnoticed, it is probable that more or less serious damage would result; possibly an active general cellular degeneration, including the cellular elements of the blood, would occur, resulting in more or less permanent damage to the patient, if not a rapid decline and death. It is only by close observation of each individual patient that the original and succeeding dosage can be determined. The drug should never be pushed to the point of salivation. His experience with this method of treatment has shown him that the maximum dosage for the original series of injections cannot be carried much beyond thirty injections without producing the conditions mentioned, and that after a period of rest, on resuming the injections, the dose carried through the second series of injections must be reduced. His routine, therefore, has been developed by experience as follows: One injection of hydrargyrum succinimidum, grain 1/5, is given every other day until thirty injections have been given. Then injections are discontinued and potassium iodide, grain iii to grain x, is given, well diluted with water, one half hour after meals for two weeks. Then potassium iodide is discontinued and no medication is given for one week. Injections are then resumed as follows: One injection every other day until thirty injections have been given, on alternating injection days giving hydrargyrum succinimidum, grain 1/5 and grain 1/10, respectively. After the thirtieth injection the same course of potassium iodide is given as followed the first series of injections; then a week free from medication. jections are then resumed, again the succinimide, grain 1/10, being given every other day until thirty injections have been given. By the end of this third series experience will direct any necessary further treatment. These recommendations for dosage are not to be considered absolute, but only a guide. Close observation of each individual patient must fix the dose of the first series of injections. At times the initial injection will produce a slight febrile reaction, after which the temperature should fall to what it was prior to the injection.

By I. S Manson.

I. The Distinction of Outbreaks of Typhoid Fever Due to Infection by Water, Milk, Flies, and Contacts.-Anderson says that the striking characteristics of outbreaks of typhoid fever due to water are: 1. General distribution of cases throughout the area supplied by a particular water. The incidence of cases is independent of social conditions, occupation, and age, except that very young children as a rule are not affected in equal proportion to other ages, due to the difference, perhaps, in susceptibility and to taking less water. 2. Explosive onset of the outbreak. 3. Seasonal prevalence; spring or late winter. Outbreaks of typhoid due to infection of a water supply previously good usually occur in the late winter or spring. This is due to the fact that infected discharges are thrown on the frozen ground, and when thaws or floods come the infection is suddenly washed into the stream. 4. Comparative freedom from the disease of persons not using the suspected water. When there is more than one water supply or where persons use pure bottled waters or boil the water, the comparative freedom of such persons from the disease is striking. 7. Bacteriological and chemical examination reveals evidences of pollution. While it is practically hopeless to expect to find the typhoid bacillus in water, still the finding of Bacillus coli in small amounts of water, and chemical evidences of pollution are additional evidence against the water. 8. Exclusion of all other probable causes. This means the exclusion of milk, food, contact, fly transmission, and other possible sources of infection. The following points would indicate very strongly that the infection was being introduced through the milk: 1. Sudden outbreak of an unusual number of cases, followed by a rapid decline. The outbreak is frequently sudden in its onset, a large number of cases occurring on a certain milk route within a few days. If the infection is introduced only once, as by flies, there is a sudden rise followed by a sudden decline in the number of cases. If there is a continuance of the infection, as from a bacillus carrier, the onset may be more gradual and the decline will be delayed. 2. The appearance of an unusual number of cases among the customers of a certain dairy. The appearance of an unusual number of cases without a general increase elsewhere on the route of a dairy should at once direct especial attention to that milk. 3. Unusual incidence of cases among users of milk. It will be found that there is an unusual prevalence of typhoid fever among the users of milk; the nonconsumers escape or secondary cases develop. As women and children generally use more milk than men an unusual prevalence of the disease among them is a common feature of milk borne outbreaks. Those families on the suspected route who make a practice of pasteurizing their milk escape, except from infection as secondary cases. 4. More cases among the well to do than among the poor. In a milk outbreak there are usually more cases among the well off, due to the fact that they are more able to buy milk and use it in larger quantities than the poor, while in fly borne outbreaks the poor and those living under insanitary conditions are more often attacked. 5. The finding of the typhoid bacillus in the suspected milk. The great part

played by flies in the transmission of typhoid fever was first emphasized in the masterly Report on the Origin and Spread of Typhoid Fever in United States Military Camps during the Spanish War, by Reed, Vaughan, and Shakespeare. They concluded that "flies were undoubtedly the most active agents in the spread of typhoid fever. Flies alternately visited and fed on the infected fæcal matter and the food in the mess tents. More than once it happened when lime had been scattered over the fæcal matter in the pits, flies with their feet covered with lime were seen walking over the food. Typhoid fever was much less frequent among members of messes who had their mess tents screened than it was among those who took no such precautions. Typhoid fever gradually died out in the fall of 1898 in the camps at Knoxville and Meade with the disappearance of the fly, and this occurred at a time of year when in civil practice typhoid fever is generally on the increase."

4. Cholecystitis .- Bettmann says that during the attack of cholecystitis the patient should rest in bed and should have warm Priessnitz compresses over the upper half of the abdomen. Opiates should be given to relieve pain if necessary. The diet should be exceedingly limited during the first few days, and all cathartic drugs are contraindicated. After the swelling of the gallbladder has subsided and the local soreness has disappeared, the patient may be out of bed most of the day. The diet should consist largely of cereals, meat, simple vegetables. bread, and butter. Alcoholic drinks, acid foods, and fruits should be prohibited. The use of salines should be begun early. Sodium sulphate, sodium phosphate, sodium bicarbonate, and sodium salicylate may be given in various mixtures. They are best administered dissolved in plenty of hot water, one half to one hour before each meal. He does not believe there is any special virtue in sodium salicylate, not possessed by the other drugs mentioned; nor does he think it advisable for the patient to eat more than the three regular meals a day. It is possible that urotropin or other drugs may prove to have unusual value. Under this simple treatment, continued for months, or if need be for years, patients are given an excellent chance to escape recurrence of inflammation, and, in fact, all symptoms referable to the gallbladder.

1. Arteries.-MacWilliam and Mackie have studied human arteries obtained at post mortem examinations, amputations, etc., with special reference

to the behavior of the vessels when cut across and measured. In the majority of cases in which dissolution has been a gradual process of an exhausting nature, preceded by high temperature, the arteries have shown no sign of contractility when coming from the autopsy twelve to twenty-four hours after death. They present all the characteristics of dead relaxed arteries. But in many instances, especially in cases of relatively sudden death, the vitality of the arteries may not be so readily lost, and contractility may persist for very considerable periods. The same is true in arteries obtained from amputated limbs.

r. Urine Examination .- Foxwell holds that the important quantitative determinations in the examination of urine are specific gravity, amount passed in twenty-four hours, percentage of urea, and amount of urea by weight. Testing the acidity is not of much assistance in estimating functional capacity. The specific gravity is more important; the persistence below 1.012 is good evidence of marked permanent renal inadequacy. The total quantity of urine passed is even more important than weight. Persistent increase to sixty ounces or more in the twenty-four hours is indicative of renal fibrosis, just as a persistent specific gravity of below Urea is the important substance to determine when investigating the condition of the nitrogenous metabolism of the body, which is the metabolism most frequently defective, and the failure of which causes the vast majority of the ailments and degenerations to which life is liable. The percentage of urea varies widely in health, but an average of anything below 1.4 per cent. during ten to twenty days nearly always indicates renal damage. The average daily output of urea of healthy kid-· neys should be about 480 grains for men, 380 grains for women. A daily output of 250 grains for a man and 200 grains for a woman are the lowest amounts on which they can respectively permanently exist without losing ground. Stable existence, at however low a level, requires this much excretion of nitrogeneous waste; people so living would have fragile lives and be unable to stand any severe strain. Summing up, the writer puts 1.012 (specific gravity), 50 ounces (amount in twenty-four hours), 1.4 per cent. (urea), and 310 grains (urea in twenty-four hours) as the lowest average analysis which would enable a man to go about doing a moderate amount of work in the world. 1.011, 45, 1.2, 238 would be the lowest which would enable him to get up and do some light work which did not necessitate regular attendance, for he would often be in-

valided. An analysis as low as 1.010, 40, 1.0, 175 would necessarily confine him to bed; or, if he got up, his manufacture of waste material would be greater than his removal of it, so that often severe breakdowns would occur during which his nitrogenous intake would have to be of the smallest to enable equilibrium to be once more established. The above figures are for men; women would have a smaller excretion, but the decrease is shown not in the strength of the solution, but rather in its amount. The female kidney does work of equal quality, but smaller quantity. There is nothing more striking than this maintenance of quality by the healthy organ. If there is less urea to be excreted, then the quantity of urine is lessened, not the strength of the solution. Hence the urea percentage and the specific gravity are the two important factors which indicate the degree of kidney damage. But a patient with damaged kidneys promptly calls upon the heart for aid, and his strength depends upon the functioning power of both these organs and not upon the kidneys alone. The increased cardiac action, by increasing the flow of blood through the kidneys, will enable these to secrete a greater quantity in any given time and so make up for the lessened quality.

"Fulguration" for Malignant Tumors .--Manders states that the combined surgical and electrical treatment for cancer, recently called "fulguration" (or treatment by lightning) has created lately a considerable and increasing interest on the Continent of Europe. The novelty in "fulguration" consists in the application of oscillatory electricity in combination with actual surgery; there is neither novelty in the technique nor in the apparatus used. The operation is divided into four stages: I. The surgeon divides the tissues and lays bare the neoplastic masses without separating them. 2. The tumor is fulgurated by the strongest, thickest, hottest sparks, so as to produce the greatest possible effect in the shortest time. The duration of this stage is from a few minutes up to ten. 3. The surgeon excises the growth. 4. Fulguration is again repeated. This is the most interesting and important stage, and lasts about forty-five minutes. The tissues become ischæmic and the cut capillaries cease to bleed. No actual scab is formed, but a fine layer of clot, which eventually becomes detached, as happens in burns. The wound is then closed, provided with thorough drainage, and covered with gauze plentifully sprinkled with sodium biborate, over which is placed a large pad of cotton wool. dressing, which is changed after twenty-four hours, is often very painful. Cicatrization is rapid after the slough separates, but complete healing is slower than after an ordinary surgical operation. If fulguration has in any way reduced to a minimum the recurrence of cancer after operation the combined operation is fully justifiable and must be regarded as a distinct gain in treatment. The demerits of the new operation are: (1) That the length of time the patient must be kept under anæsthesia is much prolonged; (2) that the anæsthetic must be chloroform, as the much more volatile ether is apt to catch alight from the sparks; (3) that anæsthesia, besides being prolonged, must be deep, because the fulguration, especially in the second stage of operation,

when the biphase method is used, is very painful; (4) the disadvantage during the operation of having to change from one instrumentation to another; (5) the difficulty of managing and controlling a rush of violent sparks; and to these must be added (6) the uncertainty of being able to reach every part of the incised area with a series of sparks which are not continuous, but intermittent. All of the disadvantages enumerated above may be obviated and greater security attained by an entirely novel method of operating, to which the writer, as its originator, has given the name "electroscision." The essence of the technique is the utilization of the continuous and undamped oscillations of electricity instead of the intermittent and rapidly damped trains of oscillations employed in the production of fulguration. The principal difference between the two is that in fulguration the spark really resembles forked lightning in its discharge, for a violent stream of sparks springs from the electrode to the most salient points opposed to it, so that it is quite possible for a germ lying in a sulcus, or even well in the open, to escape its destructive influence.

General Paralysis and Locomotor Ataxia. -Robertson and his fellow workers have found that bacilli of the diphtheroid group, possessing prominent metachromatic granules, can be shown to be invading the tissues in all cases of advancing general paralysis and tabes dorsalis. The chief seats of invasion or of infective foci are the nasopharyngeal and oral mucosæ in cases of general paralysis and the genitourinary tract in cases of locomotor ataxia. Evidence of such invasion has been obtained by the direct examination of scrapings from the surface of these mucous membranes. Confirmatory results have been yielded by bacteriological examination. Examination of the centrifuge deposit from the cerebrospinal fluid removed by lumbar puncture has demonstrated the bacilli in several instances, and in two cases the deposit has yielded a pure culture of a similar bacillus. Growths of diphtheroid bacilli have been obtained from the brain post mortem in numerous cases of general paralysis, and the organisms have also been demonstrated in microscopical sections of the brain. Two species of the diphtheroid bacilli isolated from cases of general paralysis or of locomotor ataxia are often virulent to rats and mice, whilst being innocuous to guinea pigs. Some of the rats that have succumbed have shown the cerebral changes characteristic of general paralysis, while others have suffered from acute nervous symptoms and have shown marked changes in the cortical and spinal nerve cells. Treatment of cases of general paralysis and locomotor ataxia with an antibacterial serum, prepared in the sheep by immunization with these special diphtheroid bacilli, has been attended in many cases by distinct arrest of the symptoms, indicative of active progression of the disease. Secondary bacterial infections are extremely prone to occur in the specific infective foci primarily localized in the nasopharyngeal, oral, and genitourinary mucosæ. The microorganisms especially concerned are streptococci, staphylococci, and certain diplococci. Evidence of mixed infection (pyorrhœa alveolaris) may be seen in the condition of the gums in most cases of general paralysis. In such cases not only has the primary diphtheroid

infection to be treated, but also the secondary infection. Syphilis plays an important part in the pathogenesis of general paraylsis, acting mainly by damaging the nasal mucosa in such a way as to weaken its power of resistance to certain forms of bacterial attack. As regards locomotor ataxia there is good reason to believe that as a predisposing factor gonorrheea is of greater importance than syphilis. Locomotor ataxia, if not complicated by serious secondary infections, can be combated by serious and vaccine methods. Under such treatment the lightning pains may disappear, the progress of the disease be arrested, and the general health of the patients undergo remarkable improvement.

5. "Typho Bacillose"; a Form of Tuberculosis.—Landouzy, under the title "typho bacillose, describes a type of acute tuberculosis which he holds to be anatomically and clinically distinct from the other forms of bacillary septicæmia due to the tubercle bacillus. In addition to caseous bronchopneumonia (phthisis florida) and acute miliary tuberculosis, the bacillary infection may appear as a new and distinct type of septicæmia. It is characterized exclusively by a typhoid condition, with continued fever and enlarged spleen, but no signs of visceral lesions. It strikingly resembles typhoid fever, but has the following differences. The temperature curve is very irregular, with considerable oscillations and with irregularities from day to day, and from week to week. There is also a want of correspondence between pulse and temperature, the pulse being usually much faster than in typhoid fever. And finally there is absence of symptoms of visceral lesions, of pharyngeal and bronchitic catarrh, of intestinal catarrh or constipation, and, most important, absence of all rash. When on rare occasions this form of tuberculosis ends fatally after two, three, or four weeks, the autopsy shows only the congestive and degenerative lesions common to all general septicæmias, with here and there pin head granulations, quite insufficient in size or number to set up local troubles. As distinguishing the condition from acute miliary tuberculosis there is no tuberculous ulceration in the organs, and local symptoms—pulmonary, cerebrospinal, or abdominal—are absent. While miliary tuberculosis is always rapidly fatal, typho bacillose often ends in recovery or, at any rate, in the abatement of the acute general infection. In the great majority of cases, after three or four weeks of continued fever, accompanied by more or less marked prostration leading up to the typhoid state, convalescence sets in. But, generally speaking, recovery is not complete, the patient does not get back his "go," he does not display the good appetite of so many convalescents from typhoid fever, and emaciation persists. At the end of some weeks or months, it may be, gradually or suddenly signs of local tuberculosis appear, generally in the lung or pleura, but in children fairly often in the meninges. Sometimes the convalescence appears to be entirely complete and yet, suddenly or gradually there appear later proofs of a local tuberculous condition. Cases of definite and complete recovery are very rare. The subjects of typho bacillose after they have recovered from this condition nearly always live in a condition of latent tuberculosis, and weeks, months, or even years after the

initial acute septicæmia that disease becomes manifest in them. Typhoid and paratyphoid fevers can be distinguished by means of the agglutination reaction and blood cultures, while on the other hand the inoculation of guinea pigs with blood collected from a vein, the serum reaction of Arloing, the ophthalmic reaction of Calmette, and Jousset's inoscopy afford certain evidence of a septicæmia due to the tubercle bacillus. Experiment has been able to reproduce the condition in animals with its different anatomical manifestations, its symptomatology, and clinical course. In view of all these proofs from the laboratory and from clinical experience, the writer holds that there can no longer be any doubt as to the existence of the morbid entity which he has described.

By DUCROQUET. Circumscribed Spinal Meningitis and False Tumors of By R. ROMME. the Spinal Cord.

Congenital Luxation of the Hip .- Ducroquet discusses the anatomical conditions present in congenital luxation of the hip, the manipulation by which reduction is to be accomplished, and the means of maintaining the maximum stability. The prognosis he considers to be largely dependent on the form of luxation; in anterior luxation the reduction is easy, in posterior luxation reduction is difficult and sometimes impossible.

1. Syphilide of the Skin in the Lower Monkeys. -Hoffmann and Löhe in their experiments seek to demonstrate the clinical and histological conformity of the symptoms produced by the inoculation of syphilis in these animals with the recognized symptoms of secondary syphilis in man, the presence of the Spirochata pallida, and the inoculability of certain animals. The animals used were two medium sized Cercocabus fuliginosus, the inoculations were made in the left testicle of each, a cutaneous exanthem appeared in each, the living Spirochæta pallida, stained according to Giemsa's method, was found in each, and material taken from one and inoculated into the upper eyelid of a Macacus rhesus induced the appearance of syphilitic symptoms in the latter.

2. Serum Treatment of Chronic Nephritis.-Casper and Engel report the results of serum treatment in eleven cases of chronic nephritis. Injury appeared to have been done in no case, in one the excretion of albumin and casts was permanently stopped, in some it was diminished either permanently or transiently, and in others no change took place. Almost without exception the general condition was improved, and cedema present visibly retro-

graded.

4. Fraenkel's Pneumococcus in the Blood of Persons with Pulmonary Tuberculosis .- Panichi concludes from the study of the blood of four patients that the pneumococcus can circulate in a latent condition in the blood of persons suffering from pulmonary tuberculosis, and that this micro-organism can be found thus circulating in the blood for a long time, even months, before the death of the patient.

6. Kurloff's Bodies.-Patella contends that Kurloff's bodies are true protozoa, belonging to the

7. A New Invisible Virus.—Dörr says that in many warm countries there are peculiar forms of disease which become epidemic during the hot and dry months, disappear during the cold months, and are known by different names in different localities. Whether all these diseases are identical or not he cannot say, but he has been studying the epidemic summer fever of Austria and believes it due to a contagion in the blood, an invisible virus. From the results of his experiments he believes that on the first day of the disease the virus is circulating not only in the blood, but also in the serum; that it soon disappears from the circulation, so that at the end of the second day the blood is avirulent, and that outside the body the virus shows a marked power of resistance, so that it preserves its infectiousness for at least three and a half days.

Clinical Casuistics from Practice.—Erb writes with regard to syringomyelia and dystrophy, and relates an extremely interesting case. The pa-'tient was an unmarried woman, forty-six years of age, who had suffered from childhood with a peculiar trouble in walking and had been attacked slowly, when thirty-six years old, with a disturbance in the lower limbs, consisting of an increasing uncertainty and weakness with emaciation of the legs. The sphincters were unaffected, and the sensibility apparently was affected slightly if at all. The rest of the body with all its functions remained normal. The objective condition presented different groups of symptoms in unique combination: 1, Paresis of the legs, the left more than the right, with increased tendon reflexes and distinct Babinski's symptom, but without muscular tension, a symptom complex to be referred to an organic disease of the pyramidal tracts of the lowest part of the dorsal cord. 2, Atrophy of the muscles of the legs to different degrees with clearly demonstrable partial degeneration reaction, but of slight development. This indicated an affection of the gray anterior columns in the lower portion of the lumhar portion of the cord. 3, Dissociated losses of sensation, lowered sensation for pain and temperature with preserved sensation of touch. showed an affection of the central gray substance, certainly of the gray posterior columns and perhaps of the white posterior cords high in the dorsal portion of the cord. 4, Moderate vasomotor disturbances and lowering of the perspiratory secretion. Affection of the gray substance without marked disturbances of the skin, joints, and bones. There were marked fluctuations in the intensity of all symptoms, and after prolonged treatment a slight improvement occurred. What is the diagnosis? The author excludes osteomalacia, dystrophia muscularis progressiva, spastic spinal paralysis, myelitis transversa dorsalis, multiple sclerosis, extramedullary or intramedullary tumors, spinal amyotrophy, amyotrophic lateral sclerosis, chronic anterior poliomyelitis, neurotic muscular atrophy, and other diseases until he leaves only the possibility of a syringomyelia, localized in the lower part of the body. If the combination of symptoms was located in the upper part of the body there would be little question that this was the diagnosis. Therefore he thinks that such cases should be classed as syringomyelia in-

ferior, and the much more frequently met with iorms of cervical and bulbar syringomyelia as syringomyelia superior.

3. Pneumococcus Meningitis as the Indirect Late Result of an Injury to the Skull.-Rubin reports a case in which a young man received an injury to the head and died five years later of a pneumococcic meningitis. From the clinical course of the case he tries to demonstrate an ætiological connection between the traumatism and the menin-

9. The General Practitioner and Deaf Mutism, By D. M. MACKAY.

1. On the Preoperative Treatment of Nonmalignant Gastric Disease.—Barker thinks that, up to a certain point, the preoperative treatment of the disease in question is within the domain of the family physician. When an operation is decided upon the surgeon should be responsible for the preparatory measures. It is admitted that many operations on the stomach are done on insufficient grounds, and that the results desired do not always follow even carefully designed and executed procedures. In not a few cases the patient is at fault in insisting upon an operation when suitable measures carried out by his physician would result in a cure without operation. Patients with persistent gastric trouble should be kept in bed, their mouth and throat should be sterilized, and their food should be well cooked and of simple quality. Great stress is laid upon lavage of the stomach, and as to drugs, laxatives, bismuth and betanaphtol are mentioned. If such measures do not help the patient the way is clear for operative measures.

2. Fracture and Refracture of the Patella .-Corner adduces the following factors which will assist in the recovery of perfect joint movement after fracture, and obviate the danger of refracture. I. Early operation, within twelve hours from the receipt of the injury. 2. Blood clot must be thoroughly removed from the joint, but it is not so great a necessity from between the fragments. 3. The bone fragments should be sutured with wire or silk, the torn lateral expansions on either side of the patella being also sutured. The former may be done subcutaneously, the latter through lateral incisions. 4. Dressings of gauze and collodion should be used, without splint or flexion of the limb. Gentle massage should be begun a day or two after operation, and slowly increased. The patella should be moved laterally on the femur. 6. All wounds should heal by first intention. 7. The weight should not be placed upon the foot until full movement has returned in the knee joint. A scar over the front of the patella must be avoided if possible.

3. Fracture of the Metacarpal Bones.-Mackenzie states that the x ray has demonstrated the comparative frequency of this injury. This is especially noteworthy in boys under eighteen, in whom there is frequently a separation of the epiphysis due to direct violence. Cases of fracture from indirect violence are, however, not unusual. The diagnosis may be difficult without the x ray, especially when there is much swelling and much tenderness. The points to be observed in diagnosis are crepitus, unnatural mobility, displacement, ecchymosis, and swelling. The prognosis depends very largely upon the intelligence with which the treatment is carried out. Beck's treatment is recommended, which consists in the use of a coaptation splint of short pieces of drainage tube of suitable size, applied on either side of the fractured bone on the dorsum of the hand, and held in place by a strip of adhesive plaster

4. The Necessity for End to End Apposition in Fractures of Long Bones.-Gray believes that such apposition is desirable in all cases to obtain a useful limb, and is absolutely necessary if a perfect limb is required. Primary union is as desirable in bones as it is in soft parts; healing by callus is analogous to healing by granulation. Primary union is also the quicker process, and the resulting scar is firmer. Diseases of scars are almost exclusively the result of union by second intention. Painful scar is practically nonexistent after primary union. Applying the principles of healing in the soft parts to the repair of bones, union by direct apposition is quicker and firmer than in healing by callus. Excessive and exuberant callus, chondroma, sarcoma, etc., at the site of fractures are comparable with keloid, sarcoma, epithelioma, etc., arising in scars of soft parts. Callus formation in excess also may mean very troublesome involvement of nerves.

8. Bier's Method of Passive Congestion .-Wakefield states that Bier recommends both active hyperæmia and passive congestion, according to the condition to be treated. He first used passive congestion for tubercle in 1890, being influenced by the frequency of phthisis in those whose lungs were anæmic from stenosis of the pulmonary cardiac orifice, or other cause. Hyperæmia and inflammation are beneficial, to a certain extent, being Nature's reaction to and method of counteracting injurious influences. Conditions brought about by congestion are relief of pain, abatement of fever, prevention of stiffness, destruction of bacteria, promotion of the absorption of fluids, resolution of thickenings in joints and tendons, and a certain degree of trophic action. In some cases it will produce a decidedly beneficial autoinoculation. It may be brought about by means of a bandage proximal to the area to be congested or by a suction apparatus. Before treatment by congestion is commenced it is most important to determine the nature of the discase and to vary the technique accordingly. A proper method of congestion in one case might be very improper in another.

o. The General Practitioner and Deaf Mutism. Lade that, this problem is suitable for the

general practitioner rather than the aural surgeon. Deaf mutism is incurable, but it is often preventable. There may be total deaf mutism in which there is no response to any auditory sensation, and partial deaf mutism, in which the patient can distinguish noises and even words. Destructive changes are present in the structure of the middle ear, and these may extend to the internal ear. They may be so extensive as to obliterate the cavities of the labyrinth. Fifty per cent. of the cases are due to congenital causes and an equal number are acquired. Two facts in the congenital variety are noteworthy, heredity and consanguinity of parents. This would indicate that marriage among the deaf is to be discouraged. In acquired deaf mutism brain diseases form the most important causative element, especially meningitis. Next in importance are the acute infectious diseases, especially scarlet fever, measles, and diphtheria. Constitutional diseases, especially syphilis, are occasionally responsible.

By W. P. Northrup.

1. Solving the Problem of Obstetrics,—Zinke thinks the time has come when expectant spontaneous labor, hebosteotomy, and Cæsarean section will take the place of craniotomy, induction of premature labor, prophylactic version, and the high forceps in cases of narrow or contracted pelvis. Hebosteotomy is suitable for fifteen per cent. of such cases and Cæsarean section for five per cent. Hebosteotomy and Dührssen's operation, in the interest of the child, are also of life saving character for the mother. These operations are preferable to the compromise operations, including balloon and metal dilatation. Vaginal hysterotomy should take the place of accouchement force, the repeated application of the tampon and metal dilatation. compromise procedures should be limited entirely

to cases in which infection has occurred, the presence of sepsis excluding hebosteotomy and Cæsarean section. Women who are threatened with long and difficult labor from any cause should be taken to a suitable hospital for their confinement.

2. Arteriosclerosis of the Uterus.—Rees desires to emphasize the following facts: I. A diagnosis of arteriosclerosis of the uterus is difficult to make and can only be made in cases in which it is possible to exclude all other causes of hæmorrhage from the uterus, and by microscopical examination of scrapings of the uterus in which sclerosed capillaries are found, or finally from sections of such an uterus after its removal. 2. This condition as a cause of uterine hæmorrhage in women between the ages of forty and fifty, and among those who have borne children, is more important than has generally been determined. 3. In a fair proportion of cases the hæmorrhages from the uterus are in themselves sufficient to endanger the life of a woman, and are an indication for hysterectomy. 4. Hysterectomy is justified, in view of the uncertainty of diagnosis, even after examinations of a section of the uterus, and scrapings from the same, though there may be no evidence of malignancy, in women between the ages of forty and fifty who have borne children, and who suffer with frequently recurring hæmorrhages.

5. The Mobility of the Patient after Laparotomy.-Chase states that the subject includes both The unavoidable passive and voluntary exercise. annoyance and pain which must always come after operation, to a greater or lesser degree emphasize the obligation of the surgeon to minimize such disturbance. Prolonged experience has demonstrated the needlessness and injury of the immobility, active and passive, which was formerly considered essential after operations. Such movements of the body as will tend to vary the monotony of rest in one position are no longer considered harmful, but the extreme of reaction is reached when a patient is allowed to sit up the day after an operation, to get out of bed on the day following, and to go home within a week. Perfect coaptation of wound edges, rest, and freedom from infections are the essentials for prompt recovery. Whatever disturbs these conditions is harmful. Firm healing of an abdominal wound requires at least two weeks, and whatever tends to disturb the process within that time endangers the result. The author doubts whether rest in the supine position for such a period could favor thrombosis, embolism, or phlebitis, as has been asserted.

Proceedings of Societies.

SINTH INTERNATIONAL CONGRESS ON TUBER-CULOSIS.

Held in Washington, D. C., September 28, 20, and 30, and October 1, 2, and 3, 1908.

(Continued from page 1008.)

The Pathology of Tuberculous Peritonitis.— Dr. WALTER ALTSCHUL, of Prague, said that he had found two hundred and ninety-nine cases of tuberculous peritonitis among 10,322 autopsy reports from the Deutsche Pathologische Institut of

Prag. It was formerly believed that all cases of tuberculous peritonitis originated in the female genitalia or in the intestine. Infection might be simultaneous and independent in the female genitalia and in the peritonaum, or the genital infection might be secondary to the peritoneal infection, as indicated by cases of tuberculosis of the abdominal end of the tube, and cases of recent uterine tuberculosis in which it could be proved that the infection had reached the uterus from an old tubal focus. Although the percentage of cases was greater among females than among males, the difference was not sufficient to indicate a greater frequency among women. Among the cases forming the basis of his communication, the author found that one hundred and fifty-six, or fifty-two per cent., were in women, and that only fifty-two of them showed signs of tuberculosis of the genital organs. intestine could not be regarded as the sole point of origin of tuberculous peritonitis, as there were many cases without intestinal involvement. peribronchial lymph nodes naturally suggested themselves as sources of infection, which might spread by the blood or by the lymph channels. the bacilli were carried by the way of the blood paths they would be arrested in the pulmonary capillaries and set up a pulmonary tuberculosis; but there were many cases of tuberculous peritonitis without pulmonary involvement. The fact that the peritonæum usually escaped in miliary tuberculosis was also against the blood path as the route of infection in this form of tuberculous disease. By exclusion, therefore, he arrived at the lymph channels as the route of infection. The communication between the pleural cavities and the peritoneal cavity had recently been demonstrated by Sappey and Küttner, and the latter author found that the lymph passed both ways through these vessels. The path of infection, then, would be from the peribronchial lymph nodes through the perforating lymphatics of the diaphragm, into the peritoneal cavity, chiefly to the retroperitoneal lymph nodes, which were almost always involved in tuberculous peritonitis. Cases in which the only tuberculous lesions to be found were those in the peribronchial lymph nodes. and the retroperitoneal lymph nodes proved that the infection did actually travel by that path. The tubercle bacilli might also pass through the diaphragm and produce a localized tuberculosis of the lower surface of that membrane, as sometimes occurred in early cases.

Tendeloo was of the opinion that the lymph stream could only travel from the thoracic cavity toward the peritoneal cavity when the intrathoracic pressure was greater, and he gave as one of the reasons the presence of adhesions binding the lung to the chest wall, and particularly to the diaphragm. In the material which the author examined, and which amounted to more than 10,000 autopsies, two hundred and ninety-nine cases of tuberculous peritonitis showed pleural adhesions in one hundred and twenty-nine instances (adhesion of only one pleura in twenty-six cases); in fifty-four cases the adhesion was limited to the apex; in thirty-three of the remaining forty-five cases the lungs were free, and in thirteen adhesions were not men-

tioned, so that it might be admitted that the lungs were free in these cases also. It followed, therefore, that adhesions of any extent were present in only two thirds of the cases; hence Tendeloo's theory did not apply to all cases. The author found that in those cases of so called pure tuberculous peritonitis, when the bronchial glands only were involved outside of the peritonæum, the lungs were usually not adherent. He studied 1,023 autopsy reports of tuberculous subjects with this point in view, and found that of the two hundred and eighty-one cases which showed tuberculosis of the abdominal organs, one hundred and ninety, or 67.5 per cent., had pleural adhesions; fifty-five, or 19.5 per cent., had apical adhesions; and thirty-six, or 13 per cent., were free. In the seven hundred and forty-two cases without involvement of the abdominal organs, four hundred and forty-one, or 59.5 per cent., had adhesions; two hundred and nine, or 28 per cent., apical adhesions: and in ninety-two, or 12.5 per cent., the lungs were free. Hence the percentage of cases without pleural adhesions was slightly higher when the abdominal organs were involved than in cases without abdominal tuberculosis. The author suggested the following explanation: In tuberculosis of the peribronchial glands the healing process might begin in the proximal or in the distal portion. If the infection spread (which was of course not always the case), the manner in which the healing took place was of some importance. If recovery began in the distal portion the bacilli could escape only into the thoracic duct, i. e., into the circulation. The bacilli entered the capillaries of the lung, where they were arrested and produced a pulmonary tuberculosis. If healing began in the proximal portion, access to the circula-tion was blocked, and the bacilli were carried in a retrograde direction through the perforating lymphatics of the diaphragm to the peritonæum. If several bronchial glands were affected, it was, of course, possible that healing might begin in the proximal end of some and in the distal portion of others, which would explain those cases in which a severe pulmonary tuberculosis was associated with tuberculous peritonitis, and in which both processes were secondary to disease of the peribronchial lymph glands, although one localization might appear later than the other.

SECTION II.—CLINICAL STUDY AND THERAPY OF BURGULOSIS. SANAJORIA, HOSPITALS, AND DISPENSARIES,

Continued one page 910.1

The Establishment of Dispensaries in Cities and Towns.—Dr. R. W. PHILIP, of Edinburgh. said that a dispensary should be a central institution devoted to the guidance, supervision, and assistance of the tuberculous poor. It should also be an information bureau for advice as to all the different phases of the fight against the disease; a clearing house; and a centre for the supervision of home treatment. The dispensary should be in intimate touch with the public health authorities, the registrar of vital statistics, the persons who had undertaken house investigations, the sanatorium, the hospital for advanced cases, and other institutions in which tuberculosis was treated. There was, in the opinion of the speaker, the greatest necessity for

coordinated effort on the part of all the different bodies that were endeavoring to lessen the incidence of and the mortality from the disease. He described the system which he had inaugurated in Edinburgh, and which was succeeding in bringing all the active bodies into close cooperation.

The Part Played by the Preventorium, or Supporting Dispensary, in the Social Antituberculous Fight.—Dr. A. CALMETTE, of Lille, said that the antituberculous supporting dispensary was essentially an instrument of social preservation against tuberculosis. Its function was not to treat patients; that was the part of sanatoria, hospitals, and medical dispensaries attached to benevolent organizations. Its mission was to seek out, attract, and keep under supervision, by means of an active propaganda, those among the very poor who were peculiarly exposed to tuberculous infection and those who were already infected. It selected curable patients who were suitable for sanatorium treatment; took charge of children who were menaced by or who were already attacked by the bacillus; took care of them or endeavored to cure them by placing them in the country or in seaside establishments; sent patients who were dangerous to their surroundings to isolation hospitals; sterilized dwellings; disinfected and cleaned contaminated linen; and distributed spit cups and antiseptics. In short, it brought about the hygienic education of families through the collaboration of "monitors of hygiene," chosen from among the most capable and authoritative men of the people. The sanatorium was exclusively for patients who were already attacked by the disease, but who were considered to be curable; but the preventorium extended its benefits to the families and the environment of these patients. It was a recruiting agency for academic colonies, for sanatoria, and for hospitals, and was, furthermore, a school of practical hygiene.

The Dispensary Examinations of Tuberculous Families, their Results and their Significance in the Systematic Combat against Tuberculosis.-Dr. A. KAYSERLING, of Berlin, said that the mortality from tuberculosis had been decreased nearly one half in Germany since the discovery of the Bacillus tuberculosis by Koch. The principle upon which this result had been obtained was that of destroying the cause of the disease. This was accomplished by isolating the individual who suffered from the infection and by the use of antiseptics. Dispensaries had also been established for controlling the cases and for destroying the discharges. An individual with advanced tuberculosis was the center of infection, so that he ought to be controlled early in the course of the disease, in order to prevent his case from becoming advanced. He recommended a systematic organization for the fight against tuberculosis by the establishment of stations similar to the dispensaries which had been described so often by so many writers. The dispensary, in his opinion, should be the official point of notification for cases of the disease, and from the dispensary physicians should be sent for the purpose of making an examination of the family of the patient.

The Work of the Chicago Tuberculosis Institute. ALEXANDER M. WILSON, Esq., of Chicago, said that the Chicago Tuberculosis Institute was or-

ganized in 1907. It had established seven tuberculosis clinics, which were maintained in conjunction with the large general dispensaries of the city. The institute supplied a nurse to each clinic, and through its central office coordinated the work of the clinics and prevented duplication. In less than seven months 1,400 examinations had been made. The tuberculosis clinic was fundamental to any intelligent effort to grapple with the tuberculosis problem in a large By the agency of such an institution home treatment could be put into effect in a large proportion of cases; preventive work could be carried on intensively in the places in which it was most needed; and children and other members of families could be reached early, often before the disease had gained a foothold on the individual.

The Day Camp for the Consumptive,—Dr. DA-VID TOWNSEND, of Boston, said that until recent years very little or no provision had been made in this country for the type of case which, for one reason or another, was unsuitable for the hospital for incipient cases or for the sanatorium, and which was not sufficiently far advanced to be treated in an advanced hospital or home. The first day camp had been established for such persons in Jungfernhaide, near Berlin, by the Red Cross Society, in 1900. Since that many similar camps had been started in Germany. In 1905 the Boston Association for the Relief and Control of Tuberculosis opened and operated the first day camp in the United States. It was established near Boston, and was in operation only during the summer months. In 1907 the camp remained open until February of the following year. The equipment consisted of a kitchen shack, an administration shack, a dining tent, and several smaller tents. Paper bags and crêpe paper napkins were used for the collection of the sputum, and these were collected and burned at night. The patients had two lunches and a dinner each day. They arrived at the camp at half past nine in the morning, and returned to their homes between five and six in the evening. The patients spent the day in reclining chairs at rest, or else in moderate amusement, under the direction of a physician and nurses. The chief aim of the camp was educational, and much emphasis was laid upon this phase of the work. Addresses were made by authorities upon various topics connected with personal hygiene and the hygiene of disease each season. Out of 252 persons admitted to the camp in the season of 1907, 209 roomed and slept alone, thirty-nine roomed and slept with some one else, and there was no record in five cases. Two hundred and forty-three of these patients lived in tenements or lodged, and only nine lived in their own houses. There was a noticeable improvement in eating and sleeping, with a diminution in night sweats from the start. A complete record of the home conditions was made by nurses who visted the homes of the patients. The system cost 63.7 cents a patient during the first year, with an average daily attendance of thirty-one. During the second year, with an average daily attendance of forty-six patients, the per capita cost was 63.8 cents. During the third year, with a daily average attendance of sixty-three and a half patients, the cost a patient was 51 cents. The experience had taught the Boston association that the day camp was of value, when properly conducted, as an educational centre for the patient with tuberculosis, as a means for the removal for a time of the source of infection from the community and from the home. As a centre for the proper care of the patient who was unable to go to a sanatorium, and as a place for the completion of the cure that had been started in a sanatorium. Further, the system had shown that a patient with tuberculosis was not hopeless until he was dead. It was quite likely that many patients had died from the lack of proper care. Two other camps had been started near Boston as the result of the establishment of the one represented by the speaker.

Night Camps.—Dr. Whelem Charles White, of Pittsburgh, said that the night camp, to which patients who were admited after their work for the day had been done, was of value to patients with open tuberculosis, with closed active tuberculosis, and with healed tuberculosis. Many of these patients could work from four to eight hours a day, and, of these, some needed supervision only, and others could not obtain proper care at the place in which they boarded and lodged. The night camphad a distinct educational and sociological value.

The Treatment of Tuberculosis in the Patient's Home or in Other Places than Sanatoria.—Dr. CHARLES L. MINOR, of Asheville, N. C., said that the home treatment meant to him the treatment of tuberculosis outside of a closed sanatorium. The hygienic and dietetic treatment was now recognized to be the most important part of the rational treatment of any case of pulmonary tuberculosis. These agencies were applied most successfully in sanatoria, and it was commonly believed that they could only be conducted properly in such an institution. But the speaker maintained that the hygienic treatment could be conducted just as well outside of such institutions, and often in the home of the patient. The features of the hygienic treatment included the careful personal supervision of the patient by a competent physician, the thorough instruction of the patient in the things required of him, the systematic hygienic arrangement of the patient's life, the effect of the example of other patients and of esprit de corps, nursing, proper housing, location, proper feeding of the patient, and suitable climatic conditions. All these, in the opinion of the speaker, could be obtained outside of an institution, unless the patient was treated in his own home, when the example of other patients could not be obtained, or unless the patient was so poor that suitable climatic conditions could not be had. The difficulties of handling the very poor were sociological problems rather than medical questions, as were also the handling of the ignorant and the criminal. The treatment of a chronic condition such as pulmonary tuberculosis required a different line of procedure from that applicable to the ordinary cases of acute disease. There was a necessity for much more detailed work and closer personal relations between the physician and his patient. In many cases the physician regarded the chronic case as uninteresting, tedious, and unfruitful of results. This was not the case. The patient required, however, will power and self control, determination and earnestness, patience and cheerfulness, intelligence and enthusiasm, and interest. The physician required will power and a strong personality, the ability to teach, enthusiasm, and a knack for directing details.

The Treatment of Tuberculous Patients in their Homes and Places Other than Sanatoria.-Dr. THOMAS D. COLEMAN, of Augusta, Ga., said that the details of the home treatment of tuberculous patients were of the greatest importance, because the majority of patients must be treated at home. The individual, the family, and society at large were interested in the question. Personal choice of the patient, his individual necessity, and the small number of sanatoria made that the fact. Home treatment was not to be confounded with climatic treatment or treatment in an entirely different climate from that to which the patient was accustomed, whether in the new climate the treatment was conducted in a sanatorium, a suitable home, or a boarding house. The speaker thought that as rigid discipline and as intelligent medical oversight might be had in the home as in the sana-

Tetters to the Editor.

APOMORPHINE, AN IDIOSYNCRASY?

TITUSVILLE, N. J., November 8, 1908.

To the Editor:

An article by Hernack, in the Münchener medizinische Wochenschrift, on the bad effects of apomorphine, in which he reports the action of a subcutaneous dose upon himself, dwelling upon the intense muscular relaxation and questioning whether this muscular paralysis is due to the vomiting, induces me to send you the following statement:

Recently and for some time I had under my professional care a man, sixty years of age, afflicted with a nervous trouble of the heart and a very indifferent stomach digestion. An accumulation of undigested food induced palpitation and angina to a painful degree. A hypodermic injection of one tenth of a grain of apomorphine relieved the stomach by a single emesis, distressing symptoms would subside, and in two hours the patient would resume the ordinary routine of his daily life.

Some little while back my usual good health was broken by an attack of frontal headache, which, as I had eaten heartily, I thought would be materially mitigated by a thorough emptying of the gastric contents. Unfortunately, my stomach is very tenacious of all it may receive, and has strong objections to returning goods it has not passed upon. This was in evidence at one time when I attempted emesis by ipecac, tartar emetic, and various and sundry other drugs, so a hypodermic dose of apomorphine was a natural sequence, especially with the knowledge of my recent experience with the drug in mind.

I injected a tenth of a grain under the loose skin of the arm above the elbow, and, informing a member of the family of the act and saying that in tenor twenty minutes I might be heard from, went as far to the rear of the yard as I could, that guests at the house might not hear the commotion, and there awaited results. A half hour passed without complaint from the stomach, but a peculiar "all

gone" feeling began to steal over me. My arms were heavy and my body drooped forward. My mind was clear, so much so that I wondered if the apomorphine had become changed or an error in administration could have occurred. I recalled that the tablets were recently purchased and from a most reliable firm, and I had no doubt of the accuracy in administration. I struggled to my feet and got part way to the house when vomiting ensued, followed by catharsis. I sank down under partial motor paralysis. The muscles of my arms and legs refused to respond with any degree of alacrity, the neck muscles refused to fully support the head, the jaw dropped, and saliva dribbled from the mouth. My prolonged absence caused a search to be made, and I was carried into the house. During most of this half hour my mind was clear, extremely active, then would come a space of a few seconds or minutes in which the functions of sensation or volition were suspended-a mental hebetude-followed by clear mind. To me the arterial pressure seemed normal, no evidence of failing pulse or cardiac depression; respiration normal, no dyspnœa.

At the end of an hour vomiting and catharsis had ceased, but muscular relaxation continued, and I went into a sound sleep, lasting until the next morning (this occurred about nine in the evening). This relaxed state of the muscles was discernible to a marked degree for twenty-four hours.

I will add that I am credited with an idiosyncrasy in the action of morphine, and that two years preceding this incident I received a spinal injury, some slight evidence of which remains.

MAXWELL S. SIMPSON.

Book Rotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Surgical Memoirs and Other Essays. By James G. Mumford, M. D., Instructor in Surgery, Harvard Medical School; Visiting Surgeon to the Massachusetts General Hospital, etc. Illustrated. New York: Moffat, Yard, & Co., 1908. Pp. 358.

Many of the papers in this very interesting collection have been delivered by the author as addresses, and most of them have a biographical basis, though they also serve as sketches, from the professional point of view, of the times in which the subjects of the biographies lived. The men whose lives are set forth are Hippocrates, Galen, Vesalius, Ambroise Paré, Albrecht von Haller, John Hunter, Lord Lister, Sir Astley Cooper, Sir Benjamin Brodie, John Collins Warren, and Jacob Bigelow. They are those whose names are employed in the headings, but several other famous surgeons are dealt with, including Philip Syng Physick, Ephraim McDowell, Samuel D. Gross, Bernhard R. K. von Langenbeck, and Theodor Billroth. There are portraits of Lister, Vesalius, Paré, von Haller, Hunter, Physick, McDowell, Gross, von Langenbeck, Billroth, Cooper, and Warren.

Dr. Mumford shows great skill in the brief analysis of character and in depicting men's influence on the surgery of their times. It is not entertainment

alone that is to be derived from such a book; it is a notable aid in appreciating the history of the world's surgery, and it deserves to be widely read.

Pulmonary Tuberculosis and Its Complications, with Special Reference to Diagnosis and Treatment. For General Practitioners and Students. By Sherman G. Bonney, A. M., M. D., Professor of Medicine, Denver and Gross College of Medicine, Medical Department of the University of Denver; Visiting Physician to St. Luke's Hospital, etc. With 189 Original Illustrations, Including Twenty in Colors and Sixty X Ray Photographs. Philadelphia and London: W. B. Saunders Company, 1908. Pp. vir78.

The title of this book does not describe its text adequately, as the author discusses tuberculous disease not only of the lungs, but of all other organs and tissues. The chapters are included under parts on the actiology and pathological anatomy, the symptomatology, course, varieties, and termination, the physical signs, the diagnosis and prognosis, the complications, the prophylaxis, and general and specific treatment. It is stated that the book has not been prepared for the skilled specialist, but for the general practitioner, and that it embodies largely the re-

sults of personal experience. The author thinks that the practical dangers of infection from the bacillus of cattle are sufficiently real to justify no abatement of legislative, municipal, and individual measures to suppress the disease among domestic animals, and afford protection to the human race. He believes that infection by the alimentary tract occurs much more frequently than has generally been supposed. He thinks that the essential element in the propagation of the disease among children is not the inheritance of a tuberculous taint or predisposition from infected parents, but rather an undue vulnerability of tissues peculiar to infants, and an excessive exposure to sources of acquired infection. The tuberculin test is believed to be possessed of a high degree of diagnostic value in some doubtful cases; the more recent experience with the von Pirquet and the Calmette tests is not included, though both tests are mentioned.

Prophylactic efforts of society with reference to tuberculous disease must include compulsory notification and registration, supervision of the consumptive and his environment, the tender of material aid in accordance with the needs, dissemination to the public of information about the disease, and the administrative control of all important factors entering into the problems of ætiology and prophylacia.

The final chapter of the book is devoted to treatment by "vaccines," and the author concludes that the bacillus emulsion is of undoubted efficacy in some cases of long standing apyretic pulmonary tuberculous disease, and that in such cases the possibilities of benefit are far beyond the limits of former therapeutic effort. The book is well printed and has many valuable and interesting illustrations. It is likely to have, as it deserves, great popularity.

Venems, Venemous Animals, and Anticenomous Serum Therapeutics. By A. Calmette, M. D., Corresponding Member of the French Institute and of the Academy of Medicine; Director of the Pasteur Institute, Lille. Translated by Ernest E. Austen, F. Z. S. New York; William Wood & Co. Pp. xvi-403. (Price, \$5.)

It is a matter for congratulation that this splendid monograph by Calmette is now available to the English reading medical public. The author is well

known as one of the pioneers in this branch of medicine, and through his own researches and those of his pupils he has contributed a great deal to our knowledge of the subject discussed. About half of the volume is devoted to poisonous snakes, their venoms, and the treatment by antivenoms. Some idea of the importance of this subject for certain countries may be obtained when we are told by a recent writer that in India over 20,000 persons die annually from the bite of the hooded cobra. Among the poisonous snakes common to North America one finds the water viper or cotton mouth, the copperhead, and the various species of rattlesnakes. Fourteen of the last named are described. There is an interesting account of the capture and keeping of snakes. The chapters devoted to the collection of the venom, its nature, and the preparation of the antiserum are extremely instructive, and include the results of the latest scientific researches. The complexity of the poisonous action of the venoms is well brought out, and there is an interesting discussion of the natural immunity of certain animals with respect to snake venoms.

accomplished by Sewall, in 1887, but had no practical results. Calmette, working with cobra venom, and Phisalix and Bertrand, with viper venom, almost at the same time succeeded in immunizing guinea pigs and rabbits, and produced a serum which could be used to immunize other animals passively. In order to produce serum for therapeutic purposes, Calmette began to immunize horses and other large animals. To do this effectively is no easy matter, and requires on an average sixteen months. The technique of the immunization as at present carried out is fully described. Since there are two chief constituents in snake venoms, and since some venoms are very rich in one while poor in the other, and vice versa, it is necessary either to immunize the animals against both poisons (polyvalent serum) or to employ for therapeutic purposes the poison most common in that particular country.

The latter has proved the more feasible. The serum

used extensively in India is an "antineurotoxic"

serum. The toxicity of rattlesnake venom is due

chiefly to the hæmorrhagin, and therefore in this

country the antiserum must be directed chiefly

against this principle. After discussing the venoms

The production of an artificial immunity was first

of spiders, scorpions, bees, molluses, fish, lizards, and other animals, the author reproduces a series of documents relating to the clinical use of the antivenomous serum. The illustrations, of which there are 125, are wonderfully well drawn and add greatly to the value of the book. The translation is excellent, and the book is a credit to its publishers.

High Frequency Currents. By Prederick Fixch Strong, M. D., Instructor in Electrotherapeutics at Tufts College Medical School. One Hundred and Eighty-three Illustrations. New York: Rebman Company Pp. 289

(Price, \$3.)
The rapid progress being made in our knowledge of medical electricity allows of and even necessitates frequent additions to the literature of the subject, and such accessions are especially appreciated when they come from one who is known to be so well versed in electrotherapeutics. This book, although containing but 280 pages, is well illustrated and is filled with useful knowledge. It opens with a short historical sketch of the development of the currents

of high frequency, both in America, where it originated, and in Europe, and it is gratifying to see American physicians receive their share of credit for

original work in this line.

Following this there are three chapters devoted to electrophysics or its essentials, in which a very interesting and easily understood explanation of the electron and vibratory theory is given. One hundred and ten consecutive pages are then devoted to a careful consideration of the generation of the high frequency currents, the apparatus used both here and abroad, a comparison of the currents derived from different types of apparatus, the measurement of the current, phenomena, physical properties, methods of application, etc. This difficult task has been well handled by the author, whose statements are concise, clear, and forceful. chapters on therapeutic technique, the physiological and therapeutic action of the various currents are, for the most part, ably done. The absence of exhaustive experiments, case reports, and other forms of padding allows of a clear and connected description which can be easily digested by the reader. Although the author clearly shows a preference for the Tesla currents, he gives an analysis of all the currents of high frequency, with their limitations and possibilities. Finally, there are three short chapters on the production of the x ray and the generation of ultraviolet rays and ozone by the high frequency currents. Although the author has given in considerable detail the technique of application of the various high frequency currents, he has preferred to leave out the so called essentials of the entire subject of electrotherapeutics, and he has compiled a small pocket edition containing these essentials, and advises a careful perusal of its pages as a preliminary to the present volume. .

To be, perhaps, hypercritical, we fail to see the necessity of showing the same cuts a second time, and in one or two instances we believe a better description of apparatus might be given. There are, as is usual, a few unimportant typographical errors, although one, in this instance, causes some confusion between a cut of a Piffard spiral and the text. Otherwise the book is well printed on good paper, substantially bound, and small and light enough to be comfortably held in the hands while reading. The work is instructive, up to date, and exceedingly

American National Red Cross Textbook on First Aid and National Red Cross Textbook on First Aid and National Columns Amount of Instruction How to Prevent Accidents and What to Do for Injuries and Emergencies. By Major Charles Lynch, Medical Corps, United States Army, Prepared for and Endorsed by the American National Red Cross. With Seventy-tour Illustration—Philadelphia: P. Blakiston's Son & Co. 1008. Pp. philipage. Co., 1908. Pp. viii-247.

The Red Cross is a society recognized by most governments and organized in nearly every country for three purposes: I. In time of war to render medical aid to the belligerent armies. 2 and 3. During peace to give assistance to the civil authorities in preventing accidents and to help and support these same authorities in great calamities. On account of the two last purposes, the American National Red Cross has issued this little textbook for use in schools and colleges, in families, in homes, in factories, and in workshops. It may thus be used as a manual for teaching and as a reference book in an emergency,

Edited by a surgeon of the United States army who is acquainted with accidents in war as well as in peace, having served during the Russo-Japanese war as United States medical attaché to the Japanese army, and having been engaged in organizing first aid and relief columns and lecturing before the public on such subjects, it is of great value.

The book gives a short lecture in anatomy and physiology, teaches about germs and microorganisms, takes up first aid material, and then speaks about the accidents and injuries. The index will assist the inquirer in looking up particular forms of

The Practitioner's Visiting List, 1909. Thirty Patients per-Week. Philadelphia and New York: Lea & Febiger. Pp. 192. (Price, \$1.25.)

This diary appears for the twenty-fifth year. It is issued in four styles: "Weekly," dated, for thirty patients; "monthly," undated, for 120 patients; "perpetual," undated, for thirty patients weekly a year; and "sixty patients," undated, for sixty patients weekly a year. It contains also the usual addenda, such as a scheme of dentition, instructions for examining the urine, poisons and antidotes, directions for artificial respiration, a table of doses, an alphabetical list of diseases and their remedies, etc.

BOOKS PAMPHLETS, ETC., RECEIVED

Therapeutics of the Circulation. Eight Lectures Deliv-Therapeutics of the Circulation. Eight Lectures Delivered in the Spring of 1905 in the Physiological Laboratory of the University of London. By Lauder Brunton, Kt., M. D., D. Sc., LL. D. (Edin.), LL. D. (Aberdeen), F. R. C., C. P., F. R. S., Consulting Physician to St. Bartholomew's Hospital. Published under the auspices of the University of London. With Two Hundred and Forty Illustrations. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. xi-280.

Practical Points in Anæsthesia. By Frederick Emil Neef, B. S., B. L., M. L., M. D., New York. New York: Surgery Publishing Company, 1908. Pp. 46. (Price, 60 cents.)

Principles and Practice of Physical Diagnosis. By John C. Da Costa, Jr., M. D., Associate in Clinical Medicine, Jefferson Medical College, etc. With Two Hundred and Twelve Original Illustrations. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 548. (Price, \$3.50.)

Miscellann.

An Ingenious Apparatus for Viewing Surgical Operations.—By the courtesy of the American Journal of Surgery we are enabled to reproduce from its September number the following article by Dr. Charles H. Duncan, surgeon to St. Gregory's Volunteer Hospital, New York:

In the best planned surgical theatres the provisions for demonstrating an operation are wofully inadequate. The visitor can see very little (and that little imperfectly), except the backs of the surgeons and nurses, unless he be one of a favored few who may be allowed to crowd about the table, where he is an inconvenience to those who are working and a danger to their asepsis.

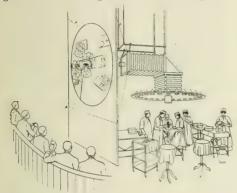

A view of all the details of an operation can be obtained only from the position occupied by the surgeon and his immediate assistants, i. e., from just above the field of operation itself. To provide that view to a large number of observers is the purpose of the apparatus here illustrated.

If a camera is vertically suspended, lens downward, directly over the field of operation, a picture of the latter can be focused on its ground glass

screen, where it may be viewed by an audience in a room above, through an opening in the operating room ceiling. By means of a prism, however, the rays of light may be made to be reflected from the operating field into a camera horizontally suspended, and focused on a vertical ground glass screen.

To accomplish this the author employs a large lens and a surface mirror, which are to be fastened in a fixture about four and a half feet above the patient. Around the mirror is a glass shield five feet in diameter, the periphery of which is supplied with lights arranged to provide a uniform, brilliant illumination without any shadows. The part of the body to be operated upon is brought under the mirror.

The illustration in general shows the aim of the invention, but it is not correct in optical and mechanical detail. The apparatus, as shown would give an inverted image on the screen in regard to

Sketch showing the author's apparatus for exhibiting an operation at close range to a number of visitors, for photographing lesions in vivo, and for separating visitors from the operating reconstitute of the street of the second seco

right and left, which, of course, is not desirable. With the assistance of an optical firm the author has been able to secure the lens and mirrors for experimental purposes, and with the aid of three combinations of lens and mirrors a positive reproduction of the field of operation is obtained upon the screen, and thereby good, sharp photographs may be secured. All lenses absorb color more or less, and were we to stop here the reproduction on the screen, while sharp and well defined in regard to linear aspect, would have more or less absence of color. We have, by means of well known methods, interposed several solutions, held between thin plates of glass, which intensify the red, orange, and green rays.

As will be seen by a study of the illustration, the vertical light rays from the operating field are transmitted, without refraction, into an enlarging camera, where they may be focused on the vertical ground glass. If the camera screen is set in a partition separating the operating theatre from a darkened room, a large number of visitors seated in the latter can secure a view of practically every step of an operation as it progresses. A megaphone set in the partition, and projecting into the operating room, will provide means by which the operator can talk to the visitors. A man stationed at the partition can make

such occasional manipulations as may be necessary to keep the image in focus, or he may photograph any stage, or, by operating a moving picture film, all the stages, of an operation.

The apparatus will in no way interfere with the operating room personnel. Its intended uses and

advantages may be thus summed up

To provide to a body of visitors the same view of an operation as though each of them had his eyes directly over the field. (Obviously operations in certain cavities of the body, e.g., the nose and the rectum, do not lend themselves to this method.)

To completely separate the visitors from the surgeon and his staff. This eliminates the danger of contaminating the operating room by dust from street clothes and shoes. It eliminates distraction of the operators by the going and coming of visitors, and distraction of the visitors' attention from everything but the operation itself. It saves the audience from the fumes of narcotics and the steam of sterilizing apparatus. It affords a means by which visitors may have plenty of cool, fresh air, without chilling the patient.

To conveniently photograph any step of an oper-

ation on a large plate.

A noving picture of an operation for preservation may be secured by attaching a moving picture machine to the apparatus. By this means the operation can be reproduced again and again for teaching purposes in medical colleges. Arranged on the plan of the "mutoscope," such a moving picture can be studied at leisure in the doctor's office, where by means of it he can have a particular surgeon perform a particular operation for him over and over until he is thoroughly familiar with its details. Thus the technique of our master surgeons can be studied and compared at every clinic, and preserved for future generations.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commis sioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending

November 18, 1908:

Barnes, W., Acting Assistant Surgeon. Granted twentyone days' leave of absence, from December 10, 1908.

BILLINGS, W. C., Passed Assistant Surgeon. Detailed as a member of a Revenue Cutter Service Retiring Board at Baltimore, Md., November 18, 1908.

BLANCHARD, J. F., Acting Assistant Surgeon. Granted two days' leave of absence, from November 11, 1908.

days' leave of absence, from November II, 1908.

Browne, R. W., Acting Assistant Surgeon. Granted twenty-nine days' leave of absence, from November 20, 1908.

Burkhalter, J. T., Passed Assistant Surgeon. Detailed as a member of a Revenue Cutter Service Retiring Board at Baltimore, Md., November 18, 1908.

Carter, P. I., Acting Assistant Surgeon. Granted five days'

leave of absence, from November 2, 1908.

CUMMING, H. S., Passed Assistant Surgeon. Granted one month's leave of absence, from October 29, 1908.

CURLEY, C. P., Acting Assistant Surgeon. Granted three days' ieave of absence, from November 18, 1908, under paragraph 210, Service Regulations.

Dynan, N. J., Acting Assistant Surgeon. Granted one day's extension of leave of absence on account of sick-

ness, November 4, 1908. Francis, Edward, Passed Assistant Surgeon. Granted ten

days leave of absence, from December 1, 1908.

KERR, J. W., Assistant Surgeon General. Detailed to represent the Service at the Convention of Mayors of North Carolina at Charlotte, N. C., November 17 to 18, 1008

Lyall, Robert, Acting Assistant Surgeon. Granted four days' leave of absence, from November 6, 1908, without

MARCOE, W. W., Acting Assistant Surgeon. Granted thirty days leave of absence, from December 2, 1908.

PORTER, JOSEPH Y., Sanitary Inspector. Title changed to read "Quarantine Inspector," from December 1, 1908.
Stearns, H. H., Acting Assistant Surgeon. Granted twenty-eight days' leave of absence, from December 4, 1908.
Thompson, W. R. P., Acting Assistant Surgeon. Granted thirty days' leave of absence, from November 23, 1908, which was the product of the production of th

nine days with pay and twenty-one days without pay.
WHITE, J. H., Surgeon. Granted eight days' leave of absence en route to join station.

Board Convened.

Board of medical officers convened to meet at the Bureau, November 23, 1908, for the purpose of making final revision of the regulations for the medical examination of arriving aliens. Assistant Surgeon General H. D. Geddings, chairman; Surgeon George W. Stoner, Passed Assistant Surgeon J. W. Schereschewsky; Acting Assistant Surgeon M. V. Safford, recorder.

Army Intelligence:

Official list of changes in the stations and duties of officers for the medical Corps of the United States Army for the core ending November 38, 1908;

BARNEY, F. M., First Lieutenant, Medical Reserve Corps. Ordered from temporary duty at Fort McHenry, Md., to Fort Howard, Md., for temporary duty. Griffis, F. C., First Lieutenant, Medical Reserve Corps.

Ordered to accompany troops from Fort Sheridan Ill., to Fort D. A. Russell, Wyo., and return to station.

Kennedy, J. M., Major, Medical Corps. Directed to report for assignment as commanding officer, Army General Hospital, San Francisco, Cal., on December 1, 1908. LEHARDY, J. C., First Lieutenant, Medical Reserve Corps

Order for sailing for Philippine service amended; will sail on January 5, 1909, instead of December 5, 1908.
PIERSON, R. H., Captain, Medical Corps. Granted leave of

absence for ten days.

Torney, George H., Colonel, Medical Corps. Relieved from present duties in San Francisco, Cal., December 1, 1908, and directed to repair to Washington, D. C., for duty in the office of the surgeon general.

WREN, R. J., First Lieutenant, Medical Reserve Corps. Sick leave of absence extended one month.

Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the week ending November 28, 1908:

Dessez, P. T., Passed Assistant Surgeon. Ordered to temporary duty at the Naval Hospital, Mare Island, Cal. HALE, G. D., Assistant Surgeon. Detached from the New

HALE, G. D., Assistant Surgeon. Detached from the New Hampshire and ordered to the Idaho.
 HOUGH, F. P. W., Assistant Surgeon. Detached from the naval proving ground, Indian Head, Md., and ordered to the New Hampshire.
 MUNGER, C. B., Assistant Surgeon. Detached from duty at the Naval Hospital, Portsmouth, N. H., and ordered to the naval proving ground, Indian Head, Md.
 NORTON, O. D. Surgeon. Detached from the naval recruits.

NORTON, O. D., Surgeon. Detached from the naval recruiting station, New York, N. Y., and ordered to continue duty in attendance upon officers and enlisted men of the Navy and Marine Corps in New York, N. Y., not otherwise provided with medicl attendance.

Births, Marriages, and Deaths.

Born.

FREUNDLICH.-In New York, on Sunday, November 22d, to Dr. David B. Freundlich, and Mrs. Freundlich, a son. Married

BARNES—TROUP.—In New York, on Wednesday, November 25th, Dr. Thomas P. Barnes and Miss Kate R. Troup.

Cory-Hunterson.-In Philadelphia, on Tuesday, November 17th, Dr. Edwin Francis Cory, of New Haven, and Miss Anna Salter Hunterson

Davidson—Hudson.—In Dallas, Texas, on Monday, November 23d, Dr. Wilson T. Davidson, Medical Department

vember 23d, Dr. Wilson I. Davidson, Medical Department of the United States Army, and Miss Mary Hudson. Greenberg—Cohen.—In New York, on Sunday, November 29th, Dr. Geza Greenberg and Miss Lena Cohen. Gross—Davenporte.—In Denver, Colorado, on Thursday, November 19th, Dr. J. W. S. Gross and Miss Ethelwyn A. Davenporte.

OLPP—SEIPLE.—In Philadelphia, on Wednesday, November 25th, Dr. Archibold E. Olpp and Miss Beatrice Seiple.

PECK—DUNCAN.—In New York, on Saturday, November 28th, Dr. Edward Everett Peck and Mrs. Elizabeth Anderson Duncan.

PEAHLER-SIMPSON.-In Philadelphia, on Saturday, November 21st, Dr. George E. Pfahler and Miss Frances Simpson.

Angle.—In Brockton, Massachusetts, on Friday, November 20th, Dr. Henry Frederick Angle, aged sixty-eight

BABBITT.—In East Orange New Jersey, on Monday, November 23d, Dr. George E. Babbitt, aged forty-nine years. KILLOUGH.—In Hummelstown, Pennsylvania, on Tuesday, Novembor 17th, Dr. Samuel M. Killough, aged sixty-seven

Norris.—In Baltimore, on Friday, November 20th, Dr. George W. Norris, aged sixty-three years. Reeves.—In Yonkers, New York, on Wednesday, November 25th, Dr. Gabriel Pellet Reeves, aged eighty-eight

SHREVE.—In Burlington, New Jersey, on Thursday, November 19th, Dr. Joseph Shreve, aged eighty-six years. Warner.—In Oshkosh, Wisconsin, on Wednesday, November 11th, Dr. Lucy H. Warner, aged twenty-seven years. Wilson.—In Chicago, on Thursday, November 19th, Dr. Thomas H. Wilson, aged thirty circli years.

THE APPLICATION OF REST AND EXERCISE IN THE TREATMENT OF TUBERCULOSIS.*

By F. M. Pottenger, A. M., M. D., Monrovia, Cal.,

Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat.

The construction of the human organism is such that its most important functions are carried on best when the body is subjected to an evenly balanced application of rest and exercise. This fact should be borne in mind in all discussions relative to the application of these principles to pathological conditions. While it might be advisable at times to enforce greater exercise than that generally employed, and while at times it might seem best to enforce almost complete rest, yet we must not lose sight of the fact that a combination of the two is always desirable, if it can be had without jeopardizing the best interests of the patient.

In applying rest and exercise to those who come under our care for the treatment of tuberculosis, we must first suit these to them as individuals, remembering that one can stand a great deal more than another. Then we must suit them to the disease and the stage of the disease in which the patient presents himself.

As a basis for determining the amount of rest and exercise to be prescribed in the treatment of tuberculous patients I would call attention to the following effects which tuberculosis produces upon the organism. Early in the disease the toxines which are elaborated by the tubercle bacilli are poured out into the blood stream and find their way throughout the body, especially affecting the nervous system and through it every important function of the body. The respiratory, circulatory, and digestive systems are all disturbed; the muscular system is deprived of its tone, and the heat regulating mechanism is rendered unstable. In advanced tuberculosis not only do we have to contend with these effects produced by the toxines, but also the effects produced upon one organ by the disturbances of function and the pathological changes wrought in

The conditions which must especially be taken into consideration in prescribing rest and exercise for a patient are, aside from the natural strength or powers of endurance of the individual, the condition of the heart and the ability of the patient to

exercise without causing fatigue, increase of cough, shortness of breath, or a rise of temperature. Of course, this does not take into consideration any of the usual complications, such as hæmorrhage, which always call for rest.

Thus, it will be seen, the problem of treating early and advanced tuberculosis is very different, likewise the treating of febrile and nonfebrile cases. In early tuberculosis the problem is comparatively simple. Most nonfebrile patients in the early stage are able to take that amount of exercise which is necessary to keep their musculature and general boddily functions in tone without doing themselves harm, while in the later stages this is not true.

The heat centre seems to be especially unstable in tuberculosis. This manifests itself very early in the disease and continues to its end. It shows itself by a rise in temperature following upon an exertion that would not affect a well person at all. In the early stage a short walk will often cause a rise of a fraction of a degree (which can be utilized in making a diagnosis), and in the later stages it will cause much more; while a severe exertion may cause a rise of several degrees. Such rises should be avoided unless the temperature is found to decline soon after the cessation of the exercise. While in early tuberculosis the harm produced by such a rise is not apparent, in late tuberculosis it is very evident.

Sometimes exercise causes such an increased amount of toxines to be thrown out into the blood stream as to produce a reaction such as that which follows the administration of vaccines made from the tubercle bacillus. A temperature due to this cause would probably not show itself at once, if we may judge from the experience gained by the therapeutic use of vaccines, for such a reaction usually comes on from four to twenty-four hours after they have been administered. On the other hand, it would not subside as quickly as many of the transient temperatures which follow immediately on exertion and disappear in an hour or two. When exertion is followed by a rise in temperature, as a rule, it is a sign that the exercise has been too severe, and the next time exercise is taken it should be reduced in amount below the point causing such

The production of fatigue should also be avoided. When a patient can take exercise without fatigue, other contraindications being climinated, such exercise is beneficial, for it strengthens the muscles, quickens the flow of blood and lymph, and indirectly influences in a favorable manner the various important functions of the body; but if carried to the point of fatigue, instead of strengthening and build-

Read before to International Congress on Tuberculosis, Washington D. C., Scheeler, et October 12, 1968.

ing up the body, the vital forces are depressed, and the patient's resisting power is, for the time, lowered. Energy that should be utilized in combating the infection is required to restore the overworked

body cells.

It has been suggested that, if exertion causes the bacillary toxines to be thrown out into the blood stream, producing an autoinoculation with bacillary vaccines, this procedure should be utilized in the treatment of tuberculosis. To this the well founded objection has been offered that such a procedure is unscientific and irrational because there is no way of controlling the dosage. I would offer as another objection that, when an autoinoculation is produced by exertion, in all except the early nonfebrile cases, it is produced at a most inopportune time, for, as a result of sufficient exercise to cause an appreciable autoinoculation, there is produced more or less fatigue. Thus the inoculation is given to the patient at a time when the body cells which must react and produce antibodies in order to bring about the establishment of immunity are in a state of depressed activity, owing to the fatigue which has been caused, consequently they cannot respond to their full capacity in the elaboration of protective substances. This theory finds support in the experiments which have been made, which show that the agglutinating power of the blood is lowered by fatigue.

Exercise may cause dyspnœa either of pulmonary or cardiac origin. If the dyspnœa is of cardiac origin and the patient's heart is not seriously diseased, providing other contraindications are not present, graduated exercise, adapted carefully to the powers of the heart, may improve its tone and strengthen its force, thus removing the dyspnœa. If, on the other hand, the dyspnœa is of pulmonary origin (due to a diminished amount of lung tissue), exercise must be carefully restricted, for exertion calls for more oxygen, and the only way the lungs can respond is by an increase in the number of respira-

tory efforts.

The heart requires very careful consideration in all discussions relative to the application of rest and exercise in the treatment of tuberculosis. It is the organ which is most affected by exercise, and likewise the one which must bear the brunt of the disease in tuberculosis. It is the most important organ that we have to consider from a prognostic stand-

point.

One of the early signs of tuberculosis is an instability on the part of the heart. While at rest the pulse may not be any quicker than normal; upon exertion it is markedly accelerated; and this condition holds throughout the disease. In health the pulmonary and systemic circulation balance each other, and the heart works without strain. In pulmonary tuberculosis, on the other hand, an inflammatory process is present, and, according to the extent and the nature of the pathological condition present, the pulmonary circulation is impeded or cut off, and to this extent the right heart is subjected to a greater or lesser strain. At the same time the heart is incapacitated for withstanding this extra strain by the degeneration which occurs in the heart muscle consequent upon the toxamia and general min an the a nell such interiorence in the ing down of the vagus in adhesions and in masses of enlarged glands.

The heart, then, must always be carefully considered in tuberculosis. It must be spared and strengthened for the great strain to which it is subjected. Early in the disease this care should be instituted, so that the patient may recover, if recovery is possible, with a sound heart. Late in the disease such care is imperative, that the patient may recover at all.

The point to this discussion is that rest and exercise must be prescribed for the individual. Neither rest nor exercise should be prescribed to the exclusion of the other. Both must be employed, and with the same care and judgment as the remedies of the pharmacopæia if the best results are to be obtained.

This discussion is pertinent to-day, when the attempt is being made to offer the advantages of scientific treatment to as many sufferers from tuberculosis as possible. If patients could work during the time when they are being treated, the cost of treatment would be reduced. The plan of manning institutions by patients has been tried with some degree of success. There are many institutions where the patients are allowed, and some where they are compelled, to do a certain amount of work. In others, practically all the service of the institution is rendered by patients. Such experiments are at least interesting, and in treating charity cases enough may be saved in maintenance to make such a plan practical; but the work should be carefully prescribed, so that the physical exertion in no wise reduces the patient's chances of recovery and in no wise retards the progress toward that end. It is impractical to make every patient work, or to make any patient work at all times, for there are times when rest is imperative.

In treating the well to do, my experience is that they do the best when they are free from cares and labor, when the exercise is prescribed for them, according to their powers and requirements. Of course, it must be borne in mind that the charity patient has much the advantage of the well to do while being treated in institutions for the cure of tuberculosis. For him, the change from his former surroundings to that of an institution is so great that he might improve even if he continued working; while for the latter the change is not so great for he is accustomed to having good food, comfortable but not always hygienic homes, and a certain

amount of good care.

My experience in treating patients taken from all social conditions impresses me with the fact that they all do best when they are free from any necessary labor, either of a physical or mental nature, but that those for whom institutional life is a great change, as mentioned before, can, if there are no contraindications to exercise, make favorable progress toward recovery and still perform tasks suited to their working capacity. But even in these cases it must be remembered that there are times when the patients should not work.

No tuberculous patient should ever enter into a game that he cannot stop at any time before he gets tired. The same is true of work. No patient should ever have a task assigned him that he cannot leave at any moment, should it begin to task his strength

If charity tuberculous patients are to work while they are being treated, the work should be carefully measured and suited to the patient and his condition. It cannot be done as a routine matter, but only after most careful individualization.

THE DANGER IN USING COW'S MILK CONTAIN-ING TUBERCLE BACILLI.*

By J. T. GORTON, M. D., Yonkers, N. Y.

The question of providing an adequate, permanent, and uncontaminated supply of potable and wholesome water is one which to-day is engrossing the attention of every municipal government in our country. But as yet only sporadically do we see communities taking up the question of pure and safe food for that army of infants on whose healthy brains and bodies will some day depend the future of our country. The rich man may easily provide proper milk for his children, but he should not steel himself against the cry of the laborer's child for milk just as pure and as nourishing; for it is on the working man's children that the work and the burdens of the country must eventually fall.

Our modern mode of living-civilization, if you like-renders more than three quarters of our mothers unfit to feed their babes as nature intended they should be fed during the early months of life. And as cows' milk, properly modified to suit the needs of each individual infant, has been found to be the most satisfactory substitute for human milk, we must look to the cow to provide for our nursling a food which is pure, nourishing, and disease free.

The time is coming when the character of a city's milk supply will be the subject of just as careful investigation by the intelligent prospective home seeker as is the status of that city's water supply to-day. We bathe in the water; use it for cleaning, for power, and for drinking. But we can make it safe by boiling or distillation before we drink it; and proper sand filtration removes most of the bacteria, thus rendering it practically safe for drinking.

We can filter milk also, but in this manner only the gross particles of dirt, which may be innocuous, are removed. After passing through a mechanical separator, which removes gross dirt and mucus (De la Val), the bacterial count of milk and cream after it is remixed is actually higher than it was a few seconds before. This sudden increase in the number of bacteria is more apparent than real, however, as the agglutinins of milk tend to cause bacterial clumping, which is disturbed by the action of the separator. Milk may be rendered germ free by boiling, sterilizing, or pasteurizing, but it is a mooted question whether so treating it does not

I believe that it is the duty of every city, town, and village in the country to constantly insure to its citizens pure, clean, wholesome milk, unaltered by preservatives or heat.

Our commercial milk, from the standpoints of

*Read at the meeting of the Alumni Association of Because Hospital, on October 7, 1908.

the bacteriologist, the pædiatrist, the sanitarian, and the veterinarian, seems to be open to an almost endless amount of study. And working with the scientist, the intelligent farmer and dealer have done much in the last few years to add to our knowledge of milk and to improve our methods of procuring it from the cow in the most desirable condition; and of safeguarding it until it reaches the consumer.

The danger to be feared in the consumption of milk is that it may contain pathogenic bacteria in number sufficient to cause disease, or may be overloaded with other forms of bacteria which tend to alter its character.

It is now widely known and generally conceded that milk is a natural culture medium, and the great milk problem to-day really resolves itself into a worldwide effort to obtain our milk free from bacteria, and to keep it so until it reaches the con-

Milk obtained from carefully groomed, healthy animals under good hygienic conditions, and with the exercising of great care on the part of the milker, always has a low bacterial count just after it is drawn from the udder. This led many investigators to the very natural assumption that the observance of strict asepsis in milking would give a germ free milk. Repeated trials failed to substantiate this belief. By counting the bacteria in the fore milk-that which is first drawn-it was discovered that such specimens gave a much higher count than either the remainder of that milking or than the whole quantity mixed. This led to the discovery that the open teat is a nidus for bacteria, which light on it from the air and multiply inside the canal. Lastly, Boekhart, De Vries, and others have drawn milk from healthy udders with sterile cannulæ, and have always obtained growths from such specimens. And von Freudenreich in 1903 examined the milk in the udders in thirteen cows immediately after slaughtering and always found organisms. These tests prove conclusively that while milking machines undoubtedly prevent air contamination of milk while it is being drawn, it is quite as impossible to procure sterile milk by their use as it is by hand milking.

It is apparent that our milch cows do not give sterile milk. However, all the tests made with the milk of healthy cows showed that with proper care it is possible to limit the bacteria in freshly drawn milk to 500 to 1,000 in 1 c.c., and the organisms in carefully collected milk have been found to be non-

From these facts it is obvious that properly obtained milk is clean, wholesome, and nonpathogenic just after it is drawn. Dr. William H. Park, as early as 1901, showed that if it was rapidly cooled to 50° F. or under, and maintained at this temperature, there was practically no bacterial increase for at least twelve hours, and the multiplication after that time was almost negligible for days. Goler, Law, and others have kept milk sweet and fresh for at least ten days.

The conclusions to be drawn from these studies give us all the knowledge necessary for the delivery to the consumer of pure milk, low in bacterial life, namely, the observance of absolute cleanliness in

render it harmful and even dangerous to the health and life of a young and delicate infant.

milking; the maintenance of the milk at a sufficiently low temperature; reasonably rapid delivery; and the use of only such milch cows as are known to

be in good health.

I have not deemed it necessary to go into the details of a proper water supply for the cattle, proper water for washing utensils, udders, hands, and suits of workers at the farm and in the cooling and bottling room, the health of the workers, the condition of the stables, milking stalls, and milk house, the grooming of the cattle, and the many other matters which must engage the attention of those who are

to produce an ideal market milk.

The market milk of Washington in 1906 showed an average bacterial count of about 22,000,000, and in 1907 of 11,000,000 in 1 c.c. The milk in 1907 was maintained and delivered at a temperature 4° F. lower than in 1906, and to this fact is attributed the lower bacterial count in 1907, a number still high enough to be appalling to those of us who consider any milk containing more than 1,000,000 bacteria absolutely unfit for human consumption. One Washington milk reached the appalling limit of 307,800,000 bacteria in I c.c., a pretty dense population for fifteen small drops of fluid. And when one stops to compare these figures with those showing the number of bacteria in I c.c. in the sewage of Boston, Mass., in which the average count from 1894 to 1901 was 2,800,000, and with the records for London, England, which show from 2,000,000 to 11,000,000 in 1 c.c. for the same period of years, the high bacterial count of the milk of many of our cities raises the question of its desirability for food even for the most hardy.

Milk is the staple article of diet of most human beings under five years of age, of the sick at all ages, and of the aged. It is the mainstay of the nursery and of the sick room; and it seems little short of wicked to feed those who are dependent upon the workers, whether through the incompetence of either extreme of age or through the ravages of disease, a food more heavily laden with bacteria than the sewage of our great cities. In July, 1900, the bacterial content of the average milk of Boston was 2,300,000. In 1900 the London milk contained between 3,000,000 and 4,000,000 bacteria

in I c.c.

Nathan Straus in a recent lecture before a class in political economy at Heidelberg University stated that he believed more attention was bestowed on the care and handling of beer than milk. He declared that as many as 160,600,000 bacteria had been detected in 1 c.c. of milk and pointed out that such figures were never equaled by sewage bacterial counts. But he could not have known about the condition of Washington's milk, for the government report shows four samples taken by inspectors from wagons with counts of over 200,000,000, one reaching the high figures quoted a few months ago. The milk of l'hiladelphia, Chicago, and Baltimore ranges in bacterial count in 1 c.c. from a little over 2,000,000 to 5,000,000. In New York city Dr. Park is quoted as having put the average in 1901 at about 5,000,000.

Rosenau truly points out that it is not the number of bacteria within reasonable limits that is of im-

portance from the standpoint of health, but the kind of bacteria in any milk and the nature of their products. It is generally known that most specific pathogenic bacteria which get into milk grow best at body temperature, and while not killed at a temperature of 50° F., are absolutely prevented from multiplying in milk kept thoroughly chilled. Very few people have any idea of the temperature of the air in the ordinary house icebox. It is a fact that many ice boxes never chill the air below 60° F., and milk and other foods, unless placed in the ice chamber in actual contact with the ice, rarely are chilled below 62° F., and much of the time are kept at a temperature close to 70° F. While this is not an ideal temperature for bacterial growth, there are many forms that increase rapidly under such conditions. It has been pointed out in a recent article that certain forms of bacteria multiply in milk kept at a freezing temperature, but they are not believed to be pathogenic. And right here, in all fairness to those producing and vending our milk, it might be said that much good milk is spoiled daily by being left for one, two, or three hours on the doorstep, sometimes in the sun, before it is taken in by the maid or housewife and deposited in the icebox. Many times more bacteria may develop in milk so ill treated than have been picked up on the rest of the journey from the bovine udder to the human stomach. And a warm icebox does much to carry on the pernicious growth which has received such impetus from its stay in the warm air.

Milk containing excessive numbers of bacteria is not fit for infant feeding. Many attempts have been made to isolate the forms of bacteria that give rise to the summer gastroenteritis of infants which causes such an enormous mortality. Much valuable and interesting work has been done, but the danger from this source has not yet been definitely traced

to any one group of organisms.

Epidemics of diphtheria, scarlet fever, and typhoid have undoubtedly been caused by the sale of milk contaminated by the contagia of these maladies. And many of us believe the presence of the bovine tubercle bacillus in our milk a menace to the health and life of all who ingest the live organism.

We know that the typhoid and Klebs-Loeffler bacilli increase in milk with great rapidity. Whether the contagium of scarlet fever increases in quantity in milk after it is once sown there is still an open guestion. The tubercle bacillus does not seem to grow readily, if at all, in any soil but living animal tissue. But it has wonderful tenacity of life and may remain virulent for weeks and even months in a proper resting place. Tubercle bacilli probably do not multiply in milk, nor do they need to in order to become a menace to the health of every user of this The tender intestinal mucous membrane of infants is very susceptible to bacteria and their actions, and is apparently easily inflamed or penetrated by the tubercle bacilli. The mucous membrane of the alimentary tract of the human being becomes less and less sensitive as maturity approaches, and the digestive juices increase in power. It is not so easy for the tubercle bacilli to penetrate the intestinal mucosa in adults and thus gain entrance to other parts, or cause an inflammatory process within the gut itself. But with the delicate mucous membrane of the infant's alimentary canal it is an en-

tirely different matter.

It must be hard for the average medical mind to reason out the object of one of our great city dailies in taking arms against the freeing of our dairies from tuberculous cattle. This paper, with its wide circulation and its vast influence over its numerous readers, has for months prostituted its power for good by conducting a campaign against the antituberculosis movement, in which it almost daily prints the valueless and biased opinions of the most ignorant and illiterate of our farmers. If a human mother is tuberculous she is not allowed to nurse her offspring. The milk from a diseased and possibly fever racked animal cannot be as wholesome as that from a healthy one. If milk coming from a herd infected with tuberculosis can be procured unquestionably tubercle free, the best that can be said for it is that some of it came from sick animals, and that its food value is therefore lowered.

Brush, on pasteurization, has said that if we lower the nutritive value of an infant's food we lower the babe's resistance and increase its chances of tuberculous invasion; that he considers robust health a sure guard against tuberculous infection by any route; that any illness lowers the nutritive value of a cow's milk; that pasteurization of milk of a lowered nutritive value increases the objections to its use by rendering it more difficult of digestion.

Sterilized milk is almost universally used for infant feeding in Paris, and, while it has resulted in a marked diminution in the death rate from intestinal diseases, yet in young children the tuberculosis mortality has increased.

We have all had the opportunity of observing the effect of a sharp maternal febrile movement on the nursling. It would seem only reasonable to expect, that milk from a cow having a rise of temperature would be likely to upset the digestion of a bottle baby.

There are many diseases from which milch cows suffer that make the milk unsafe for food, but more animals suffer from tuberculosis than from all the other diseases. Then, too, tuberculosis is chronic and progressive in its nature, and some animals have the disease for years before they succumb to it.

It is estimated that the dairies of the United States harbor about 29,000,000 cows, one third of which have tuberculosis; and experimental tests have shown the milk from a majority of our dairies to contain tubercle bacilli. From an economic standpoint it would pay the farmer to rid his dairy of this scourge, and there is now available sufficient knowledge of cattle breeding to accomplish this most desirable result.

The enforcement by the State of the tuberculin test raises a storm of protest. The statement is ignorantly made that the test is very uncertain, because autopsy fails to expose large areas of disease in all reacting animals slaughtered. The best authorities believe it to be exceedingly accurate, and assert that even one broken down gland will cause a reaction. Nontuberculous cows are not injured by a proper dose. Its great value lies in the very fact that this test exposes incipient cases, and thus

permits the dairyman to take the precautions neces-

sary to protect his healthy stock.

Schroeder has ably demonstrated that a cow with no physical signs of disease may have millions of virile tubercle bacilli in every ounce of the thirty pounds of dung that passes her bowels daily. He also discovered that every cow with bovine tubercu-losis expelling bacilli in any way showed them in the fæces. It is easy to see how this material, scattered over almost every part of the average cow barn, is ground into dust and falls into the drawn milk from healthy and diseased animals alike; is licked by the stock from walls and stanchions, and is inhaled by the cows and their attendants. Several investigators have recently proved that the real source of most of the tubercle bacilli in milk is cow dung. It was formerly universally believed that no tubercle bacilli entered milk except from diseased udders or lungs. As there is no way of determining when an animal so slightly infected as to show no physical signs of the disease, but reacting to tuberculin, may begin to pass virulent tubercle bacilli by the rectum, the value of this test, and of special observations of reacting animals, is apparent.

Almost any unfiltered specimen of milk procured under the conditions ordinarily obtaining on the average dairy farm contains visible particles of cow dung which may have dropped off from an unclean belly or udder, or have been switched into the milk by a dirty tail. Microscopic particles of manure may fall into the old fashioned milking pail from the air or be deposited by the feet of flies.

All the sources of manure contamination of milk may be removed except the dust in the air, and in clean milking stalls that can be almost eliminated. But under the most ideal conditions some cow dung may be dried and ground into dust, which may fall into the milk with any tubercle bacilli contained in it. And if this is true airborne bacilli from the dung of a diseased cow may enter the lungs or drop into the drawn milk of a healthy animal in a remote stanchion.

It therefore seems logical to conclude that the greatest danger from the tuberculous cow lies in the infectious character of her manure.

The United States Public Health and Marine Hospital Service showed that seventy per cent, of the milk of Washington contained cow dung; that approximately one fourth of all the cattle supplying their milk were tuberculous; and that between seven and eight per cent. of that city's milk contained virulent tubercle bacilli. That this condition of affairs is not confined to Washington, or even to the United States, is shown by the findings of pathologists at home and abroad. The New York City Board of Health have found tubercle bacilli in ten per cent. of the milk entering the city in cans. The milk of Manchester, England, has been shown by Brittlebank to contain from three per cent. to twelve per cent. of tubercle bacilli at different times. Bröers, of Utrecht, gives tubercle bacillus infection for ten per cent. of the milk of Holland.

The contention is frequently made that if bovine tuberculosis is transmissible to children it must be through the milk, and if all milk containing tubercle bacilli was capable of producing tuberculosis very few of us would escape. Very few of us do escape—entirely. And just how many of those who eventually die from tuberculosis have their first, and perhaps only, invasion of tubercle bacilli from milk during infancy and childhood will probably never be known.

Let us suppose that a few tubercle bacilli enter the stomach at a time of digestive derangement and escape destruction by the digestive juices, penetrate the intestinal mucosa, and are deposited in a mesenteric gland, or may be carried to a bronchial gland, or to any remote part of the body. These few bacilli may not be able to cause enough local disturbance to produce symptoms. They may not even, at the time of deposit in their new resting place, be capable of multiplication. They may be overcome by phagocytes and destroyed, or hold their own and lie dormant, in which case, at some subsequent and possibly remote date, when the invaded individual's bodily resistance has been lowered from any cause, these bacilli may become active, multiply, and cause inflammation with all of the accompanying phenomena. We see a tuberculous gland, a joint, or an abscess as the result. And if the milk used during the few weeks or months just preceding the development of symptoms can be shown to be tubercle free the bovine bacillus is exonerated from blame. Very few men now dispute the existence of two types of tubercle bacillus, but it yet remains to be proved that bovine bacilli that have lived in the human tissues for months or years may not have become changed in type, and have acquired the characteris-

tics of the human type of organism.

There seems to be no question to an open minded student of this problem that infection takes place both through the air breathed and the food ingested. And it is only the question of just how large a percentage is chargeable to the bovine type found in dairy products, that is under discussion. Large numbers of the type of case that seems to me to be chargeable against the account of the milch cow are cases that recover, and in which we have no way of determining the type of bacillus causing the inflammation. I refer to that large group of joint and bone tuberculous lesions that come under the care of the orthopædic surgeon, and that are cured by immobilizing the affected parts and by appropriate constitutional and hygienic treatment. . Almost ninety per cent. of the tuberculous joints manifest themselves before the age of seven, or during the period of life when milk constitutes a substantial part of the diet. More than fifty per cent. of the cases of tuberculous cervical adenitis manifest themselves during the same period of life. About seventy-five per cent. of the cases of Pott's disease are well established before the age of twenty-one. I speak of this particular group of cases because of the age at which they are found—the age of greatest milk consumption-and because it seems much more probable that bacilli deposited in the ends of the long bones and in the vertebræ especially, gained entrance to the blood stream through the intestinal mucosa and the thoracic duct, rather than from an infected pulmonary tract.

There is no doubt that from a primary pulmonary tuberculous focus a general miliary tuberculosis may develop; or in cases with small lung involvement oc-

casional cases of infection of some part of the genitourinary tract may occur. And these cases, together with Hodgkin's disease and tuberculous peritonitis, are found more often in adults than in children. I believe the infection of all remote organs, even with a primary lung involvement clearly established, often takes place through the intestinal route and by means of the thoracic duct, and comes from the swallowing of bacilli laden sputum. I believe tuberculous meningitis is acquired through the same route.

It has always been exceedingly difficult to discover the source of infection in a majority of cases of tuberculosis. It seems to be exceptionally so in proving the bovine origin of any given case.

Before the British Congress for Tuberculosis Koch, in 1901, stated authoritatively that tuberculous cattle were not a source of infection to human beings. He also stated that the human type of tubercle bacillus would not infect cattle. Both of these statements have been absolutely disproved many times and by many observers since Koch made his assertions.

Shaw has stated that in the American literature for the past seventeen years he could find records of only twenty-nine positive cases of bovine tuberculosis in human beings transmitted through the

milk of diseased cows.

Since Koch started the controversy the bovine type of bacillus has been demonstrated at autopsy and postoperative in the laboratory by various competent observers as the cause of disease and death in a certain percentage of the cases studied. Notably the British Royal Commission in a study of sixty cases found the bovine type in fourteen, or almost twenty-five per cent. of the cases. It is interesting to note in this connection that in Great Britain primary intestinal tuberculosis is much more common than in other countries. The records show from eighteen per cent. to thirty per cent. at autopsy. Taking this fact and these figures into consideration, together with the percentage of cases with the bovine type of bacillus reported by the Royal Commission, milk containing tubercle bacilli looks to be a likely source of the infection in a large percentage of the cases in children. Tuberculous infection of the milk of the British isles is about as great as in any other country.

I quote the following two sentences from a recent paper on this subject with a view of refuting the argument. "Statistics from all sources show that tuberculosis is relatively rare in the first six months of life, and that the greatest number of cases occur between the second and sixth year. tuberculosis milk was such a great source of danger, the greater number of cases would appear before the second year." I have already attempted to show that it seems probable that many cases do not develop any symptoms until months or years after they become infected. I have also pointed out the high percentage of the cases that are primary in other parts than the lungs that develop before the age of seven, most of them never having any recognizable pulmonary signs. The intestinal route seems the more likely one followed by the invading bacil-

lus in these cases.

As great an authority as von Behring, who as-

serts that all tuberculosis is of bovine origin, believes that in all cases the bacilli enter the system during childhood, and in most cases remain latent for years. Calmette concurs with him in these beliefs. There are so many cases of pulmonary tuberculosis in which the source of infection seems unquestionable, that it is not easy to understand how any one can insist that the healthy husband, who apparently contracts the disease from an infected wife, really owes his illness to old latent foci of the disease which gained entrance to his tissue from the milk he drank as a child. On the other hand, we do not know that such foci may not have existed in many cases of pulmonary infection traceable to direct contact, and we cannot be sure that such an early insidious infection may not have rendered the whole organism less resistant to a frank pulmonary invasion.

Most men are agreed that there are two types of tubercle bacilli, bovine and human, that differ in virulence, cultural characteristics, and morphology. And no fair minded observer now contends that bacilli of the human type may not cause disease action of the conversely. Koch's assertions of 1901 were based on his failure to transmit human tuberculosis into cattle. Since that date it has been ac-

complished experimentally many times.

There is no doubt that adult cattle are much more easily infected with the bovine type of bacillus than with the human. But we have not yet proved that, under similar conditions, the bovine type of bacillus is less infective to human beings than is the human type. I believe the young animal, whether baby or calf, is much more susceptible to either type than the adult of either species. It is an accepted fact that certain germs lose their virulence for some species of animals after passing through certain others, but yet prove still more virulent to a third species. It is not true that the tubercle bacillus loses its virulence for cattle by passing through man, although its virulence is much lessened.

Experiments showing the comparative susceptibility of animals to the human and bovine types of bacilli have been conducted by de Schweinitz, Dorset, and Schroeder, on calves, pigs, monkeys, guinea pigs, and kittens, in which every animal used was tuberculin tested and found tubercle free. All animals were kept under the conditions necessary to make such work scientifically reliable, and the infection was introduced through the alimentary canal in

milk.

Tubercle bacilli of human and bovine origin possess equal pathogenic power for hogs. The human type of bacillus causes tuberculosis in thirty-three per cent. of calves; the bovine type in one hundred per cent., showing that the human type is only one third as infective to the young of cattle as is the bovine type.

Both types of cultures are highly infective to monkeys. Young cats are susceptible to either type of organism. Guinea pigs are susceptible to both

types of bacilli.

Debroklonski says tuberculosis may certainly infect animals through the digestive tract. He found that the tubercle bacillus will pass through the nor-

mal intestinal mucosa, and may do so without leaving any trace of its passage.

Another observer fed sixteen young pigs on milk from tuberculous cows. In all the disease developed, and autopsy showed only one primary intestinal lesion, but diseased mesenteric and cervical glands in all. Tjaden believes the majority of our cases of tuberculous cervical adenitis in children may be caused by infected milk, and that infection through the intestines is not often accompanied by intestinal lesions.

These observations make it clear that the tubercle bacillus finds easy access to the animal economy through the intestinal mucosa; that the bovine and human type of bacilli are equally infective to most animals, cattle, however, being three times as susceptible to the bovine type as to the human, and that young animals are readily susceptible to food infection.

There is no longer any doubt that the bovine type of tubercle bacillus can and does infect man. The only point at issue is the percentage of cases infected that can be laid at the door of the cow. I believe that few, if any, adults acquire tuberculosis by the ingestion of infected milk, butter, or cheese. Is teems reasonably clear that the great danger in the use of contaminated dairy products is for children, especially young children, and that the special source of danger lies in infected milk. Butter and cheese form a negligible part of the diet of children under six years, and, while they have recently been found to be infected with tübercle bacilli to an alarming degree, I believe they do not constitute a very grave danger for children.

If we are agreed that infected milk is undoubtedly capable of causing human tuberculosis, the question of just what percentage of human disease is due to this source is second in importance to the problem of ridding our milk of this menace to our

childrens' health and lives.

There are two possible methods of accomplishing this result—to free our dairies of tuberculosis, or to so treat all infected milk that the contained tubercle bacilli are destroyed. Obviously the proper procedure for many reasons is to clean up the dairies. It would be the ideal thing to do. But between the accomplishment of this tremendous task and the present status of dairy conditions, we have an economic problem so vast that it has a marked deterring influence over every move in the right direction. The expense entailed by the destruction of dangerously tuberculous milch cows; by the sequestration of those reacting to the tuberculin test; by the special examinations necessary to determine when an animal with latent disease becomes a menace to the consumers of her products; by the improving of the animals' quarters, the milk house, and the apparatus for cooling and handling the milk. cannot be borne by the individual farmer or by the dealer. At the present market price safe milk would have to be produced and sold at a loss in most instances.

And yet the State would hardly be permitted at this time to shoulder the burden of the expense of destroying all dangerous cattle and of making the changes necessary at most of our thousands of farms. An adequate inspection alone, together with the maintenance of a proper laboratory staff and equipment, would cost the State a tremendous sum annually. In the long run I believe it would pay; and I am optimistic enough to believe that within the next decade a movement to have the State shoulder the responsibility of vouching for our milk will be well under way. It will mean an appreciable advance in the price of milk. Nearly all other necessities have advanced steadily in the past twenty years, and we ought to be willing to pay a fair price for milk. It may be necessary for philanthropy to come to the assistance of some part of the masses in providing a higher priced milk for their children, but that would be a far pleasanter charity to assist than the building and maintaining of sanatoria, hospitals, orphan homes, departments of charity, and the potter's field. Society as a whole is the loser through the loss of the work, the health, and the lives of its workers. And society is benefited by every movement which helps to improve the conditions and health of the poor and the working class. Good, pure, clean milk for the whole country, for rich and poor alike, would be a benefit to society at large, and society, the State, must pay the price.

The advantages of so treating contaminated milk that the tubercle bacillus is surely destroyed are more than counterbalanced by objections to this method of insuring its safety. Heat seems to be the only agent that we are at present free to use to destroy bacteria in milk. Boiling, sterilizing, and pasteurizing at 167° F. for twenty minutes will render milk sterile. The greater the degree of heat used theoretically the more difficult infant digestion of the milk becomes. And, while the bacteria themselves are destroyed by a sufficient degree of temperature, their products are still in the milk and may

Pasteurization seems to be a lax term indicating the heating of milk at some temperature below 180 F. for varying lengths of time. In the work of the St. John's Milk Dispensary we have found that a temperature of 167° F. maintained for twenty min-utes renders most of the milk we receive sterile. The bacterial content of the milk delivered to us in cans varies from 50,000 to 280,000 in 1 c.c. work of Freeman and others, who have found that a temperature of 140° F. maintained for forty minutes kills the tubercle bacillus and all other pathogenic bacteria, induced us to try the effect of this technique in our dispensary. The results were determined by bacterial counts, in which we found from 1,000 to 6,000 bacteria in 1 c.c. As we are nearly always able to get a sterile product at 167° F. for twenty minutes, and as bacterial growth is very rapid in milk that has been heated, we decided to stick to our old method. It has been proved that a temperature of 140° F. will not destroy the enzymes of milk and will kill all pathogenic bacteria contained. But, considering the fact that heat destroys the bactericidal action of milk, and the fact that the testimony is conflicting as to its comparative digestibility raw, pasteurized, sterilized, and boiled, the value of the enzymes in aiding its digestion is really not satsfactorily proved.

There is some evidence pointing to pasteurization as the cause of rickets and scurvy, but except in the

case of very young and feeble infants this danger seems to be negligible. In France, where sterilized milk is widely used, infantile scurvy is unknown.

Advocates of pasteurization assert that this process renders milk more digestible than the raw fluid, and point out that most other foods are cooked. The scope of this paper will not permit of a careful consideration of all the many mooted points relative to pasteurization.

To state the matter briefly, infants naturally depend on raw human milk for sustenance. Where this is not available, or proves unsuitable in a given case, cow's milk is the best substitute, and raw cow's milk, properly modified, is certainly a more natural food for a nursling than milk which has been heated.

For older children and adults heated milk may have no serious objections to its use. For infants in hot weather pasteurized milk is a safer food than questionable milk of uncertain bacterial content.

And this brings us back to the main point at issue, namely, the prevention of the presence of live tubercle bacilli in market milk. And general pasteurization of milk is certainly the easiest way of accomplishing this end. It is also the most slovenly and unbusinesslike method of accomplishing a desired purpose. It is curative when our efforts should be preventive.

The knowledge that all milk is to be rendered sterile by heat leaves no inducement for the enterprising, clean, and up to date farmer to produce a high grade of milk for which he could obtain a fair price. It puts no ban on dirty utensils, diseased cattle, filthy methods, and improper transportation facilities. Old, dirty, germ laden milk may command just as good a price as the best product of the most modern dairies if it bears the stamp "pasteurized." General pasteurization of milk, whether performed by dealers or municipal bureaus, robs the producer of all incentive to produce clean milk low in bacteria, and puts a premium on filth and disease in our milk.

In conclusion, I may say that the presence of living tubercle bacilli in milk constitutes a grave menace to the public health. The danger is greatest for bottle fed infants, next in gravity for children under five years, and least of all for older children and adults. The only sure and satisfactory method of removing this menace to health is to free our dairies of tuberculosis, and that once accomplished, to keep them tubercle free.

Pasteurization of milk used for infant feeding during hot weather is often desirable, but the greatest purpose served by so treating it is the prevention of gastrointestinal disorders, not tuberculosis. Summer pasteurization of milk alone should be countenanced, and this does not protect the infant from the tubercle bacillus except for a small part of the year. General and constant pasteurization of market milk should not be permitted to displace strenuous and proper efforts to rid our dairies of tuberculosis, as such a course under the best management will merely give us a product free from living organisms, but possibly rich in dead bacteria and their products; and will leave no incentive for the production of clean, wholesome milk.

IST PARIS ALSET.

TUBERCULOSIS.

A Clinical Problem in the Tenements.*

By R. A. Taylor, M D., New York.

The subject of tuberculosis is just now engaging the medical mind of the whole world, and laymen are so well acquainted with its various phases that I must apologize for intruding on your time on this occasion. But I am compelled to help lay the matter bare before you, because it seems hard to remember that tuberculosis retards our progress, that tuberculosis kills.

In this necessarily brief paper, I shall assume that this well informed audience is sufficiently acquainted with the subject to help me to discuss it as a prob-

lem of the tenements.

As you well remember, tuberculosis is an infectious disease caused by the *Bacillus tuberculosis*, whose invasion of any part may be followed by local or by general pathological changes. Since it is more or less manifest in certain anatomical structures, it is found convenient to designate it after these parts; but the process is not in consequence localized; for a general tuberculosis may result from very slight local manifestations. We find it as an acute infection or as a chronic process. We find it invading bone tissue, lymphatic glands, internal organs, and even the brain; but the form in which it appears most frequently is the pulmonary; and with chronic pulmonary tuberculosis we have mainly to deal.

We may realize, perhaps, the enormity of the subject when we consider that in this State alone 95,000 persons are constantly sick and 14,000 die annually of pulmonary tuberculosis. Coming still closer home, we can say that, although the death rate in New York city is reduced by one half in five years, yet statistics show that not less than 30,000 persons are constantly crippled, impoverished, and menaced by death through pulmonary tuberculosis alone.

That I may the better enlist your sympathy and cooperation for measures likely to be proposed, I must tell you, though only briefly, that a vast amount of work has already been done to aid suffering humanity against this scourge; and that there has fallen in this battle such an army of physicians that it would appal you if I but mention the number; for consumption has been investigated and combated since the dawn of medicine. But when the nineteenth century brought advanced ideas and finer instruments of precision, medical investigation received a remarkable impetus; and foremost of the achievements of this age of experimentation was the immortalizing discovery that tuberculosis, or consumption, was caused by the bacillus of Koch.

Around this discovery have been heaped the findings of workers in every nation; and upon this have been built many systems for the elimination of the plague. Most of these are only too well known to need rehearsing; and every one present has much knowledge of the efforts made to keep milk and meat free from tuberculosis taint. Still, tuberculosis makes headway; until now, almost in desperation, medicine has come to claim the sun, air, and fields. that, through skill acquired, it might press them into

the service of healing.

For it must truthfully be said that the sanatorium, wherever properly conducted, has proved an unqualified success. Yet, on this very account, since it has taught us the value of sanitation and hygienic living, it has also defined the limitations of the results of treatment, and marked them as consequent upon the stages of the disease, and upon the extent of tissue involvement. The sanatorium has opened our eyes to the difficulties of early diagnosis; to the unsuspected extent of the disease itself; and, therefore, more than ever, we see the subject as a problem of the home.

We may almost, without concern, pass by the higher types of homes; for, unfortunately, tuberculosis is a disease mainly of the poor, and the tenements typify it. After much deliberation and expensive experimentation, leaders of medical thought seem at last to conclude that, if great gain must be made in this combat with the disease, we of the tene-

ments must do the bulk of the work.

But, to successfully combat the disease in its stronghold, we need to mark the conditions which aid the specific germ. Indeed, some workers believe that, except for the aid of outside influences, the *Bacillus tuberculosis* is not actively harmful. We need, however, not challenge this statement, because these aids are ever present among the poor. For the tenements are close, dark, damp, and almost always overcrowded. The average dweller lacks food, heat, and clothing in winter; he lacks fresh air and sound food in summer, and through all the seasons he lacks the knowledge necessary for self preservation.

The average tenement in this city, until lately, lacked facilities for cleanliness; and the foul influence it generated and disseminated did not conduce to the promotion of diligence in matters of health; so that the average dweller became as one with his quarters. And here, also, one finds the extreme of sociability; you can share with the average poor man his bowl and pipe, his meals and bed; he asks no

questions, but welcomes you as you are.

It would be superfluous to go into details as to how these matters aid the development and spread of the disease. I had better quote from a recent writer. He says: "At 18 Clinton street, back in the rear tenement, a young Bohemian Jew lay dying of consumption. I had come in with a Jewish doctor. With every breath I felt the heavy, foul odor from poverty, ignorance, filth, disease. In this room, ten feet square, six people lay on the floor, packed close, rubbing the heavy sleep from tired eyes, and staring at us dumbly. Two small windows gave them air from a noisome court-a pit twenty feet across and five floors deep. The other room was only a closet six feet by seven, with a grated window high up opening on an air shaft, eighteen inches wide. And in that closet four more were sleeping, three in a bed, one in a cradle. The man's disease was infectious, and yet for two long weeks he had lain there dying. From his soiled bed he could touch the one table where the two families ate; the cooking stove was but six feet from him; the cupboard over his pillow." After more details of description, he adds: "There are 361,000 such closets in the city.

Since we now possess larger light on the subject, we can the better face the great question, "How shall we handle tuberculosis in the tenements?" And

^{&#}x27;Read before a meeting of the National Medical Association, held at St. Mark's Church, New York, August 25, 1908.

here let me impress upon you the idea that this question deeply concerns high and low alike; for there is none but must come in contact with these tenements. We must help the Chinaman, for he tends our laundry; the Jew, since he makes our clothing; the Italian, for he provides our fruit; and so on through all the ramifications of our complex social life.

And we must, also at the outset, put aside any preconceived notions concerning heredity, and think of tuberculosis as an infectious disease. For until we get this idea deeply rooted into our minds, we cannot comprehend the measures looking towards the eradication of the disease. We must repeat it again and again in church and lodge room, at home and abroad, that consumption, which carries off our most promising and our best loved ones, is an infectious disease communicated by the ordinary means of social intercourse; and is not the sin of the fathers visited upon the third and fourth generations. cannot imagine it necessary to adduce proof before this convention: for even if the time permitted, the balance is so largely in my favor it would embarrass me to lay argument before you. I therefore cite you one instance only in support of my contention: In a small town in North Carolina, a consumptive white man died in his house. The rest of the family, for one reason or another, left for distant parts. house was closed for ten years until a colored family rented it. They used the rooms except the one in which the man had died. For some reason they kept this one closed most of the time. But they began to sicken, and in a very short while consumption had wiped out the entire family. So well known and so robust had they been that the board of health took pains to investigate the matter, and they obtained pure cultures of virulent bacilli from the bed posts and from the walls of the room which the colored people had not occupied. I may mention that the then president of the board of health, who gave me the facts, had been for almost two generations the physician of that colored family; and he asserted that no case of consumption had ever before been known in that family

By what channels the infection enters the system, whether by the alimentary or by the respiratory, admits of too much controversy; for competent authorities assert the one, and equally able men swear by the other; but suffice it to say, that all possible channels of infection should be guarded. For what does it matter that tuberculous cows be destroyed while we preserve the consumptive chickens and pigs? What does it matter that you avoid direct contact with the consumptive man when you both fondle the same domestic cat?

But since we must come in contact with this disease, we ought, therefore, to take sane measures to insure our safety. Of those means now at our command, sanitary instruction to the afflicted and similar instruction followed by the healthy, show the best results. Suitable occupation, rest, diet, fresh air, sunlight, and cleanliness are powerful factors in establishing protection, though they may not insure manually. And we ought, also to think about vital capacity in our children, beginning with the prospective parents; and in infancy and childhood develop them by careful diet, physical culture, and

other hygienic measures, so that we may promote in them a blood of high bactericidal power.

Upon measures to cause recuperative blood reactions, the medicine of the future is now based. A vast amount is being done to obtain a serum or some other material whose introduction into the body will cause blood changes sufficient to arrest or to cure tuberculosis in any stage. We are almost on the eve of the developments that will insure immunity to tuberculosis, whether or not these discoveries bring to light a cure. It is yet too early, however, to speak of the opsonins or to lay too much stress upon any laboratory product; but we are approaching relative immunity, and attention to hygienic measures will shorten the distance.

Now, the effective carrying out of the ordinary hygiene of the tenements depends, in great measure, upon the simplicity of the procedures. But to get even simple matters attended to, however, the people must be taught to regard them as necessary.

Physicians and organizations such as this must find ways and means to convince them that tuber-culosis is infectious and communicable. We must disseminate the knowledge that it can be prevented if the living conditions are suitable; that sunlight, fresh air, rest, food, and cleanliness strengthen the individual and weaken the germ; and that it is possible to secure these valuable aids.

For instance, should the layman ask, "How can these things be done in tenements as they are to-day?" we make answer that the penetration of sunlight can the better be accomplished by having as little drapery as possible; and that the light will be augmented and diffused if the walls be white and the furniture not too abundant. Ventilation can be secured without draught by the many simple window devices happily found everywhere; and the skillful physician may, in winter, press the lace curtains into his service, though fashion meant to rule against him. House cleaning becomes easier when the rooms are not so crowded with furniture, bric-à-brac, rugs, easels, and stands, which at times make walking perilous.

But if they become victims of the disease, what then? In the light of present knowledge one is never too early to seek skilled medical service if benefit or cure is to be obtained, for the cure of consumption is almost limited to early cases.

Before such a gathering it would be unnecessary to define an early case; but it might not be out of place to remind you, since most of us are limited to the practice of the tenements and their like, that the diagnosis of tuberculosis in its incipiency is, for the most part, very difficult. And yet it is here that all our energies must be concentrated if the spread of consumption is to be arrested; for to the large army of tenement physicians will fall the burden of the necessary painstaking investigations. Here the busy man must accustom himself to the evidences of the disease in dim light and cramped quarters, where answers are evasive because of peculiar insurance clauses, fear of isolation, and other social reasons.

And here must eye, ear, and touch acquire especial acuteness; for, although in this and other cities the public service provides everything for expert diagnosis, the people do not avail themselves of

these privileges until cough or hæmoptysis develops. The very necessities of the case, then, compel us to rely for the diagnosis of early tuberculosis on the older methods of inspection, and so forth. And I would impress upon those of my fellow workers situated far away from laboratory facilities that they need be not one whit backward if they train the special senses.

These family physicians can and must watch for the family; and should see that they do not expose themselves to infection; or when exposed must search diligently for evidences of the disease. For rarely does it happen that an experienced practitioner accustomed to life among the lowly need be so perplexed that laboratory diagnosis becomes a

necessity.

December .c. o S.

When such is the case, however, one can turn for more light to several laboratory methods more or less helpful. Without special skill, for instance, a modified Calmette's solution of tuberculin may bring about the so called ophthalmoreaction. I should mention the x ray, because it has become a familiar office appliance; but, to say nothing of the difficulties of technique in skiagraphy, I fear few of us would be satisfied with our findings. The microscope is too common to need mention, especially as its findings are relatively late.

The opsonic index, which just now is on every lip, has not been sufficiently tried to warrant sound conclusions; but I would recommend it to this body as worthy its serious attention. There are modifications in the technique which may enable even the less skilled worker to investigate on his own be-

half.

Still, these finer methods are only secondary and are resorted to only if we have been alert enough to suspect tuberculosis. The tenement physician will, therefore, watch his family and will consult his laboratory upon occasion. And the tenement worker will need to watch also that unknown quantity represented by boarders and other migratory persons. Here the chances for continued observations are not so good; and yet, in a general way, considering the peculiarities of the case, much can be done if organizations such as this hold meetings and distribute literature to popularize the subject, so that the physician may find people more anxious to inquire of him.

In this way we may see many an early case, sent by neighbors and friends of these itinerants, cases which ordinarily would have consulted the patent medicine vendors until too late for skilled treatment. Here, then, is one way of caring for a patient, and so protecting many unsuspecting intimates and asso-

ciates.

But to approach the matter more squarely, what are we going to do when these people come to us? The State and the private sanatoria prove to us the great benefits of rest and abundance of light in the open air; but it is plain that for these people, whom we represent, there will be no rest in the open air except we could follow the example of the charities organization of this city in making up for loss of wages, paying rent, and so forth. This is an exceedingly large project, and the money necessary to carry it out puts it beyond the range of effectiveness at

Neither does the question of change of occupation apply to them, and moving to more suitable quarters is little more than a popular saying; so that, if we tend these people with hope of cure, we must treat them where we find them.

Foremost, then, among all measures to be taken will be the lessons in sanitation, which we, as physicians, must find ways and means to instill into them. It is surprising how much can be done in this way, even in the most squalid quarters. Under one pretext or another one can, in twenty-four hours, transform many a dingy corner into a habitat of cheer. For instance, it is well known that workers in

lime arrest and even escape consumption. Taking advantage of this knowledge, one may have the family whitewash the walls, ceilings, and cellars. the family may get a breath of outside air, while a sulphur candle "kills the germs." The baby, even in an improvised carriage in the back yard or on the sidewalk, will cause the mother to frequently open the window and breathe fresh air. The scrub brush may be made a toy; a new style of bed making will cause many a hidden thing to disappear: and many ways will suggest themselves to a tactful physician for beneficial yet inoffensive changes. But I would caution you that this is a physician's privilege, not to be shared by any other person; and I can assure you that if you properly approach these people you can turn most of these tenements into miniature sanatoria.

To build up resistance by other than hygienic means we may have to resort to drugs; and, if so, the selection and direction must be left to the physician. We cannot go far astray with drugs, if, first of all, we know their value and their limitations. The blood must be built up by measures directly applied, if such there be, or by measures to prevent hæmolysis. The therapeutist will know what is best for his patient.

Surely, there can be no one in this association who has not seen great good from arsenic, nux vomica, opium, bone marrow, codliver oil, diet, alcohol; and the use of these must now, when subjected to the skilled therapeutist, prove as potent as in the past.

Nor can any one doubt the value of attending to pressing or to annoying symptoms. The intelligent physician will use drugs whose value he has tested, and will employ the route of administration most effective in each given case. But I venture, because of the inconveniences of tenement practice, to suggest hypodermic medication as presenting special

advantages.

As yet there is no reliable specific, nor any routine treatment, that has proven effective or convenient for tenement work; but remarkable results can be had if we utilize all the knowledge we now possess of hygiene and blood building. And I am impressed with the belief that, given intelligent cooperation by the laity, we can, with these means now at our disposal, cure most incipient cases, and raise the blood index so high in the tenements as practically to exterminate tuberculosis.

But the problem assumes its greatest gravity when the consumptive finally takes to bed; for anxious visitors who bend over him to sing and to pravinhale particles of sputum. The ordinary individual. even when advised, will not try to protect others; and when the days of fast failing strength overtake him, those around will find it well nigh impossible

to escape droplet infection.

And when we remember the large number of beneficial orders, the solicitous neighbors, the friends and relatives, who, through humane feelings, are ever exposed to such a dread possibility, one cannot wonder at the spread of tuberculosis. So long as it must be done, these hopeless cases also must be treated in the tenements; but the hardships of incompetent nursing, the difficulty attending the handling of the sputum, the wear and tear on the overworked bread winner, all call loudly on this convention for help.

I would, therefore, recommend that this National Medical Association take steps in all congested communities to provide suitable places for such persons, as must through necessity need them, to pass their remaining days; near enough that they seem not neglected by relatives and friends, yet sufficiently distant and isolated to avoid wholesale infection.

And the layman will do his duty and render his share of service by creating in his community such a feeling of common brotherhood that would cause it to spare no pains in making this place at once attractive in appearance, inviting and comfortable within.

267 West Fortieth Street.

CONTRIBUTION TO OUR KNOWLEDGE OF THE .ETIOLOGY OF DEMENTIA $PR\Breve{\mathcal{R}}$ COX.*

(Preliminary communication.)

By Morris J. Karpas, M. D., New York. Physician, Manhattan State Hospital: D

Assistant Physician, Manhattan State Hospital; Deputy Assistant Neurologist, New York Hospital for Nervous Diseases.

(Concluded from page 1068.)

Sociological Conditions and Occupations .-"Other causes, such as the herding together of the proletariat in great cities, in bad rooms or tenements with insufficient food and unhealthy employment undoubtedly weaken the nervous system, etc.' (Forel). Most, if not all, of my patients came from the congested districts of greater New York; they lived in tenement houses; they were deprived of light, proper sanitation, fresh air, and good food; they worked in sweatshops for means of getting their livelihood; they were in constant struggle and strife for the maintenance of their existence. Some of the married women were compelled to work in shops, in addition to their housework, in order to support the family. Seventy-two patients did housework; thirty-three were employed in shops; three had positions in stores; eight were dressmakers; two were bookkeepers; three stenographers; one a governess; one an attendant in a hospital for the insane; two clerks; one a student; four had no occupation.

Sex.—Dementia præcox affects both sexes. Deny and Roy believe that this disease is equally distributed in both sexes. According to Kraepelin sixty four per cent. of hebephrenics were men, fifty-eight to fifty-nine per cent. of the catatonic and paranoid forms occurred in women. Women were the majority of Croq's cases. All my patients were females.

Previous Diseases.—Some authors state that meningitis and trauma in childhood or early adolescence should be considered as predisposing factors in the ætiology of dementia præcox. However, Kraepelin gives no recognition to such views.

In my patients a history of the following affections, in addition to the usual diseases of childhood, was obtained:

| Name of the disease | Number of ca |
|----------------------------------|--------------|
| Head injuries | 7 |
| Convulsions during childhood | 3 |
| Tardy coordination and dentition | |
| Meningitis | 2 |
| Deafness | |
| Indigestion | I |
| Constipation | 2 |
| Psoriasis | |
| Dy-menorrhœa | 10 |
| Headache at the menstrual epochs | |
| Excessive flow | |
| Interrupted menstruation | 9 |
| Irregular menstruation | 2 |
| Eczema | I |
| Urticaria | |
| Neuralgia | I |

Masturbation.—The question whether or not masturbation is an important cause of insanity is still sub judice. "Venturi, a well known Italian alienist, regards masturbation as strictly physiological in youth; it is a normal and natural passage toward the generous and healthy passion of early manhood; it only becomes abnormal and vicious, he holds, when continued into adult life." (Havelock Ellis).

Stanley Hall asserts: "In discussing the results of onanism, we must first of all recognize that the immediate and sensational effects often seriously believed in, and often purposely exaggerated for pedagogic effects, are not so immediate or disastrous as represented in both the popular and the earlier literature. The brain is not literally drained away, dementia, idiocy, palsy, and sudden death are not imminent, nor is there any peculiar infallible expression, attitude, or any other manifestation instantly recognizable by experts. Current impression to this effect has much to do in causing terror, shamefacedness, and some of the bashfulness, and solitude seen."

According to Freud the erotegenic zone in men is extensive and its reactions are manifold. For instance, he asserts, that the suckling of a baby, apprehensive states, unnatural love of a child for parent, constipation, etc., are types of morbid sexual gratifications. If such a conception of masturbation is accepted, then a skeleton could be found in the closet of every individual, irrespective of nervous or mental affection.

Aschaffenberg thinks that neither onanism nor abstinence causes a mental disease, but the imaginations which are associated with this abnormal act. Masturbation can only then exert a pernicious influence when it is carried on in a senseless manner, or the patient shows a marked predisposition to neuroses or psychoses. Denv and Roy believe that exaggerated masturbation may act as a debilitating Ziehen states that onanism is given as a cause by patients for their mental disturbance on account of their self reproach and hypochondriacal ideas. "It is possible," continues the author, "that its ætiological significance is only slight, yet it cannot be excluded; in a few cases excessive onanism through its exhaustive influence associating with abnormal psychical irritability may aid the development of a psychosis. In many instances excess of early developing onanism is a symptom of an underlying psychic disease." Kraepelin alleges that the persistence of masturbation should be considered not a cause, but a symptom of the malady. "On many grounds," says Kraepelin, "we speak in favor of sexual life, which undoubtedly plays an important rôle in this disease (dementia præcox), but not under any circumstances can onanism be

ascribed as the cause for it.'

In my patients to obtain a reliable history of masturbation was by no means possible. The laymen regard onanism as a vice which they do not wish to readily admit, in a female especially. Whenever a mother or a sister is questioned about patient's sexual life, the usual reply is "Oh, my Minnie is not such a kind of a girl," or "she is too proud to do such a thing," etc. Again, one cannot rely on the patient's information, because it is either exaggerated, minimized, or denied. Thus in my cases the evidences of onanism were adduced from gynæcological examination. A reddened vulva was considered a positive sign; a lacerated hymen in absence of gynæcological affections was regarded as suspicious; married women were not accused of being addicted to this habit. Twelve and thirty hundredths per cent. were positive; nineteen and twenty hundredths per cent. were suspicious; sixty-four and forty-eight hundredths per cent. were negative. To be sure, these data cannot be considered scientifically accurate. It must also be emphasized that in those patients, who presented positive somatic stigmata of onanism, there were other ætiological factors which were responsible for the mental maladv. It must be remembered that these signs were detected only when the psychosis was fully in progress. It is questionable whether masturbation in these patients was an effect rather than causative. Better methods of psychopathological analysis, and careful anamneses, will, in the future, solve this important and difficult problem.

Civil Conditions.—From the statistical data so far adduced it appears that the majority of cases of dementia præcox occurs in the unmarried. Tschisch believes that sexual abstemiousness in a strong constitution is an important ætiological factor in the production of catatonia. This author draws his conclusions from a limited number of cases, and, moreover, his patients came from a low strata of

civilization.

In the chapter on age it was shown that a great number of cases occurred at such period when matrimony would at the present time be considered impossible on account of economic difficulties, and in some instances consummation of marriage would be regarded as illegal. It must not be forgotten that married life in itself offers a favorable soil for the development of this disease. For instance, conjugal discord, abortion, childbirths, puerperal affection, etc.

Last year one hundred and seventy-two cases of dementia præcox were admitted to the west division of Manhattan State Hospital; one hundred and fif-teen of them were single; forty-six married, and eight widowed, and three were separated from their husbands. In my series of cases the civil conditions were as follows: Eighty-three single; forty-six married; one widow. In nine, married life was decidedly gloomy. In four, husbands contracted syphilis before marriage. Out of these forty-six women, six had no children, and in the others the number of children varied from one to six, as will he seen in the following table:

| Number of women | Number of children cach woman had |
|--------------------|-----------------------------------|
| 10 | 1 child |
| | |
| | |
| | |
| | |
| I | 6 children |

Pregnancy, Childbirth, Puerperium, and Lactation.—In twenty-four per cent. of Kraepelin's cases of dementia præcox, pregnancy, and childbirth were considered as causes. Of Aschaffenburg's 132 puerperal cases, forty-six were dementia præcox. He classified them according to their respective periods.

| Period. | | of cases. |
|-----------|----------------|-----------|
| | toward the end | |
| | | |
| Lactation | | II |

In Munzer's 101 puerperal cases, fifty-three belonged to dementia præcox group; eleven of them occurred during pregnancy, twenty-eight in puerperium, and fourteen in the lactation period.

Of my 130 patients, only twenty-one developed dementia præcox during pregnancy, puerperium, and lactation. They may be tabulated under the following headings:

| Period. | | | | | | | | | | | | | | | | | | | | | | | | | | | lumber cases. |
|------------------------|---|---|---|---|---|---|---|---|---|---|---|---|--|---|---|---|---|---|---|---|---|---|---|---|---|---|------------------|
| Childbirth | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Pregnancy Lactation | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Lactation | ۰ | ٠ | ۰ | * | ۰ | ۰ | ۰ | ٠ | ۰ | * | ٠ | ٠ | | - | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | ۰ | U |

The relation of these patients to psychotic traits and heredity may be shown by this table:

| Period, | chotic traits and | Psy- chotic traits only. | Heredity | No hered- ity or psychotic traits. | |
|------------|----------------------|-----------------------------------|----------|---|---|
| Pregnancy | . 2 | 2 | I | I | 6 |
| Childbirth | . 2 | 2 | 3 | 2 | 9 |
| Lactation | . 0 | 0 | 4 | 2 | 6 |

Trauma.-It is generally conceded by such careful observers as Kraepelin, E. Meyer, Deny and Roy, Croq, Muralt, and others that trauma is an exciting ætiological factor in dementia præcox, especially of the catatonic form. However, it is by no means of frequent occurrence. Croq, in his 300 cases, found only four in which trauma was ascribed as a cause. Muralt recorded seven cases of catatonia of a traumatic genesis.

Only in two of my cases injury to the head was held responsible for the mental malady. Both of

them showed catatonic features.

The following are complete records of these pa-

Case VI.—Kate M. Admitted November 29, 1905. Æt. twenty-five; single; Ireland.
Family history: Negative. except that paternal second cousin was somewhat eccentric, occasionally laughed and smiled to herself, fond of solitude, easily frightened, was never committed to a hospital for the insane; she lived and held a position as school teacher in Ireland. Father suffered with rheumatism.

Personal history: Patient's early childhood was, as far as is known, uneventful. She entered school at the age of three and a half, and graduated at the age of fourteen. She was always quiet, somewhat deaf, but fairly cheerful and bright. At ten she sustained an injury to her head.

but no serious consequences resulted. Catamenia appeared at fourteen, complained of pain during the flow. At seventeen menses ceased for six months. In Ireland she worked for her mother and in a dressmaker's establishment.

She immigrated to the United States in 1898, and here she was employed as domestic. In this capacity she was efficient. In January, 1902, she fell off from a trolley car, sustained indefinite injury for which no medical aid was

necessary.

In the early part of February, 1902, patient began to suffer with insomnia, and frequently mouned and groaned in her sleep. In the latter part of the same month she became suddenly apprehensive; commenced to talk to herself; came suddenly apprehensive; commenced to talk to herself; refused food because it contained poison; imagined the conductors on the cars were going to kill her; thought her sister would send her away. She became very religious and prayed all day long. She heard voices on the street and still maintained the idea that the conductors would kill her. She was very depressed, was frequently subject to crying spells which she was not able to explain. She was then cert to Rellegue. then sent to Bellevue.

In the psychopathic ward patient was depressed, consumed most of her time in crying; however, at times she smiled. On admission here, March 7, 1902, physical examination showed nothing abnormal. Mentally she was depressed, had no adequate appreciation of her condition, and was somewhat confused. On the next day patient was dull, perplexed, obstinate, took no interest in her sur-roundings, and was mentally inaccessible. In April, 1902,

patient was restless, excited, quarrelsome, and was noted as simple and childish in her manner. She frequently talked to herself, and was extremely untidy about her personal appearance. At times she was destructive, noisy, ex-citable, yet at other times she was dull, indifferent, and would manifest no interest in her surroundings.

On October 30, 1905, patient was allowed to go home on parole, contrary to the advice of the superintendent. Her condition on December 28, 1904, was described as follows: Patient is dull, simple, laughs in a foolish manaer, answers no questions, and assumes a sitting posture all

During her two months' residence with her sister patient was at first able to do some housework, as, for instance, dry dishes, do a little dusting, etc., provided she was urged to do so. She would answer questions relevantly. As a rule she would assume a sitting posture and look out of the window, apparently taking no interest in her surroundings. She attended to the calls of nature promptly. At times she was talking to herself; this was usually observed in the morning. About two weeks before admission to Bellevue Hospital patient refused to do housework, would not answer questions, paced the floor to and fro, and would continually ask for more food. She was then taken to Bellevue

On admission here physical examination showed fair nutrition, deep reflexes increased, organic reflexes impaired, dullness over upper and lower lobes left side, pleural friction rubs on right side, râles over apices and lower left lobe, bronchial breathing, crepitant and dry râles on lower right side, and cardiovascular apparatus apparently normal.

Mentally, patient was markedly indifferent, smiled in a childish fashion, held her left hand firmly over the mouth, and refused to answer questions. She did not comply with and retused to answer questions. The did not compy any requests, indulged in many mannerisms, and was markedly resistive. The following is a sample of her spontaneous production: "Go home-don't you dare take no plank to home and mind your business."

hit me with the poker—get up and mind your business." On the next day she talked constantly to herself, showed a tendency to maintain fixed attitudes, no delusions or haltendency to maintain fixed attitudes, no delusions or nat-lucinations were established, although it was observed that she frequently repeated the following phrase: "Don't you hit me with the poker! Don't you hit me with a broom!" Her condition remained without important change till the the resident, which control on Max 11, 1007 from pul

monary tuberculosis.

CASE VII.-Ida C. Admitted to this hospital, August 1, 1 119 Russia (Hebrew); single.

Family history: Maternal aunt tuberculous

Personal history: Patient was born in Russia in 1882. During gestation mother suffered from uterine hæmor-

menstruation was late, irregular, and accompanied by head-

At twelve she sustained injury to her head. Two weeks later she commenced to talk in a foolish fashion, was depressed, cried without cause, imagined there was a fire, and pressed, cried without cases, magine there are frequently spoke of it. At night she was restless, Her speech was incoherent. She was nervous and excitable. Ouite often she would be angered and resistive. This con-Quite often she would be angered and resistive. This condition lasted one year. When excitement subsided, she was considered mentally deficient. She did not return to school because it was feared she would not be able to get on with her studies. At frequent intervals she was subject to a spell of excitement, during which time she was incoherent in speech, irritable, and showed peculiar behavior.

At the age of eighteen she came to the United States,

and was here employed in a shop.

About one year before her removal to Bellevue Hospital she became depressed, could not work, would remain in the house, could not sleep at night, said people wanted to injure her, and was afraid that she might do some harm to others. She became forgetful, would lose her way, and at times was much excited.

When admitted here on August I, 1903, she was quiet; smiled in a childish fashion; answered in monosyllables; turned her head away from the examiner in an indifferent manner; offered nothing spontaneously; was not accessible mentally. A few days later she became extremely restless. whined, jumped up from bed and yelled at the top of her voice, and manifested assaultive acts. She was not able to

explain her peculiar behavior.

During her residence in this hospital patient's condition remained without important changes. At times she was quiet, somewhat irritable, industrious, manifested but little interest in affairs of life, and appeared simple and childish. When questioned she laughed and did not seem to view her situation seriously. Quite often she became disturbed, much excited, made grimaces and gestures, gave forth incoherent productions, laughed and giggled in a puerile fashion, and showed general hyperactivity. These periods only lasted from several days to a few weeks

Alcohol.-Kraepelin maintains that alcoholic intoxication is of no practical significance in the ætiology of dementia præcox. Serieux shares the same opinion. Of Croq's 300 cases, in two alcohol was supposed to have caused the disease.

Excessive alcoholic indulgence in two of my patients determinated the psychoses. In other cases alcohol acted as a subsidiary cause. The records of

one case will serve as an illustration.

CASE VIII.-Margaret O. Admitted May 24, 1906. Æt. twenty-five; Ireland; married.

Family history: As far as known family history was negative for psychopathic and neurotic taint.

Personal history: Little was known of her infancy and

She was always cranky, fond of quarreling. She suffered from asthma, and used alcoholic beverages as a therapeutic measure. For at least four years she took one half pint of

whiskey and two glasses of beer daily.

In 1892 she married (her husband had syphilis); gave birth to two stillborn children; one premature child (seven

months old).

For about four or five months before her commitment she became forgetful and absent minded.

On March 26, 1906, she gave birth to a child (stillborn); labor was difficult, instrumental, and under narcosis

Three months later she commenced to show bizarre actions, and would carry on foolish conversations with her neighbors. Soon she began to hear voices; men were coming through the window to kill her, heard shooting, and thought she was going to be murdered. On one occasion she wanted to jump out of the window because men with guns, revolvers, and daggers were going to take her life. She accused the neighbors of talking about her, and calling her bad names. She also saw various objects on the wall, and otten addressed imaginary personages. She became uncontrollable in her behavior, and on April 26, 1906, she was sent to the alcoholic pavilion of Bellevue Hospital, and later transferred to the psychopathic ward.

showed accelerated cardiac action, fine tremor of tongue and hands, sordes on lips and teeth, and no pupillary anomalies. Mentally patient was depressed, anxious and apprehensive. She talked in a disconnected manner and her answers were irrelevant. She spontaneously remarked:
"Oh, now they are going to kill me and poor Martin—now "On, now they are going to kill me and poor Martin—now I would not go home with Jimmie—(looked behind her as if listening to voices)—I see my brother and uncle coming—I said in Corona, L. I., my uncle lives—I am not going if you are not going to take me—I did not think I was coming here—you will get nothing to kill my head—(looks coming here—you will get nothing to kill my head—(looks around)—I suppose it was under my pillow in sleeping—no you will not cut off my head—I would like to see you do it—it was Jim and Frank that brought me here—I thought I was coming to Bellevue Hospital—oh, no, not downstairs I will go," etc. She did not admit feeling sad or apprehensive. She said that people spoke ill about her and that the neighbors called her vile names. She was asked whether she heard her undels young and the said. asked whether she heard her uncle's voice, and she said, "No, it must be a terrible voice to talk over the ocean, he was thrown out of Bellevue and nearly drowned, Uncle Morris got his head cut when he was drunk. Uncle Tom was at the window. I said Uncle Tom, get away from the water because he would get killed." She knew the day and year; gave the month August for May. She did not know the nature of the place, and when informed of the character of the hospital, she said: "Well, I guess Martin O'Brien is more insane than his wife." On account of her irrelevant answers, it was impossible to test her memor

For several months she continued to react to hallucinations, was usually urged with questions, and in general her

behavior was odd and peculiar.

For past eighteen months her condition underwent no important changes. She was inaccessible; often muttered to herself in a low tone of voice; laughed in a puerile manner; maintained a seclusive attitude; at times became impulsive and assaultive; inclined to be resistive, obstinate and negativistic; did not take care of her person, and it was necessary to dress and undress her; wetted and soiled herself. Her speech was incoherent, obscene, and profane. Frequently she made irrelevant remarks and her replies were not to the point. When questioned she turned her head away and expressed a volley of abusive language. At times she answered questions by saying "Aha!" or "I don't know." Mood was that of irritability and indifference. Orientation was doubtful. On account of her inaccessibility it was impossible to establish hallucinations, delusions, or the integrity of her memory.

Physical condition fair. Pupils were equal and reacted to light and accommodation. Knee jerks were exaggerated.

No tremors. Speech was good.

Case IX.—Ellen M. Admitted to the hospital on June
4. 1904. Æt thirty-four; Ireland; married.
Family history: Father at the age of fifty suffered from

a traumatic psychosis, from which he recovered. Paternal aunt was temporarily insane.

Present history: Patient's infancy, childhood, and adolescence accompanied by no abnormal phenomena.

She was always quiet, seclusive and reticent.

At the age of twenty she married a man of alcoholic habits. Matrimonial life was gloomy. She had four children and one miscarriage

She took alcoholic beverages moderately, but for about three years prior to her admission to the hospital her in-

dulgence in alcohol was excessive.

In March of 1904 she became depressed, imagined some-thing terrible would befall her, feared that she might kill

her people, and thought that she was a devil.

In April her son ran away, and she did not seem to worry over this episode. She was not able to sleep well because she thought her husband would do her harm. Shortly before her commitment she made several attempts at sui-Upon admission to this hospital physical examination revealed good nourishment, papular eruption, slight tenderness over the nerves in the left arm, exaggerated knee jerks, and gastrointestinal disturbances.

Mentally patient was at first quiet and compliant, but later appeared suspicious, uneasy, and her attention was difficult to control. Spontaneously she said: "I have drank a lot of whiskey lately-I am nervous-and I hear Jesus calling me—you are not going to do anything with me, are you? I meditated killing my children. I am going to Jesus—He is calling me—they say, come down to Jesus—will you let me come down?" She stated that she committed sins and that she contaminated everyone who came in contact with her. "I have no complaints," patient said, "of no one but myself—I have done lots of wrongs, and God Almighty knows everything I have done."

The peculiar trend of thought could be illustrated by the

The peculiar trend of mought count be intestacted by following answers to questions:

Do people watch you? "They did, I guess—the police watched me because I must have been crazy and meditated killing my children." Why did you plan to kill your chil dren? "I because I thought I was enough." Do you hear any other. aren: "I because I thought I was enough." Do you hear voices? "Yes, I hear God's voice." Do you hear any other voices? "I have heard other voices—I hear Jesus's voice saying, 'Help, help, help, help, help, Help, and I am so afraid to die myself that I wished I had died long ago." Is this a loud voice? "No, it is a weak voice." Where does it come from? "It comes from the floor and either comes from hell or heaven—I think lesus is in hell suffering for me." Do or heaven—I think Jesus is in hell suffering for me." Do you see visions? "I don't know, I imagine I see the Blessed Virgin and other things—I don't know whether I see them or this is a dream." Are you afraid? "I afraid to die—I am afraid of the devil—I wanted to die—I cut my wrist-I must have been crazy.

Her orientation was defective. Memory for recent and remote events was not affected. Retention was poor. In June she became quieter, oriented, but at times was

uneasy and restless, reacted to auditory hallucinations, and expressed ideas of self reproach.

During the year of 1905 she seemed to show some improvement mentally. However, she appeared indifferent, active, reticent, and at times gave expression to bizarre For instance, she asserted that she got the doctor's

soul from purgatory, etc.

During the year of 1906 she was often excited, disturbed, destructive, and manifested assaultive acts. In speech she was voluble and incoherent, and mood was that of irrita-At times she expressed grandiose ideas. Once she said that she was in possession of everything, and that she was Mrs. Roosevelt. She admitted hallucinations, but

showed no effect. For the past year patient's condition remained without important changes. She was calmer, appeared always happy, and spoke in an incoherent and reminiscent strain. She made many irrelevant remarks, and her answers were rambling and at times not to the point: Do you hear voices? "I hear my own child and husband—perhaps he voices? "I hear my own child and husband—pernaps he is dead and in heaven. They know all about me." Who? "I suppose anybody." Her statements were inconsistent, as for instance, one of her children came to the kitchen, but would not talk to her. A few minutes later she remarked: "I don't believe that my children are living—I don't see why I was put here." Thought Jesus and her child are in her body and that "they say we were buried together and the mother killed her son." She often spoke of heing poisoned by her mother. Her orientation was of being poisoned by her mother. Her orientation was good. Mood was that of indifference; had recently expressed the wish of returning home, but had no plans for the future. As a rule the visits of her relatives exerted no influence upon her.

She took care of her person, employed herself fairly efficiently, and at times became assaultive.

There were no neurological symptoms

In other patients alcohol was only an accessory factor, and this case will serve as an illustration:

Case X.—Catherine N. Admitted January 7, 1907. Æt. forty-one; Ireland; white; married; housewife. Family history: Brother insane. Patient's son is a

psychopath

Personal history: Patient received a common school edu-cation. At twenty-five married; had had one child. No history of serious illnesses. She did not indulge in alcoholic excesses before the appearance of the psychosis. was always considered irritable, had a bad temper, and

About fifteen years ago she imagined that people persecuted her, and expressed delusions against her neighbors. She asked her husband to change their residence. In the new be fairly well, but was rested by doctor who considered her to be mentally deranged. Ever since then she imagined that some misfortune would befall her husband and child. She would frequently become excited, irritated, and even assaultive. These periods of excitement grew more in frequency for the last three years.

About seven years ago she commenced to take alcoholic beverages in excess, and would become intoxicated periodically. She thought whiskey was a great medicine for her. About the same time she refused to have marital relations with her husband. In 1900 she conceived the idea that theatrical announcements were means of advertising her. She misinterpreted objects, occurrences, and persons

Since 1903 her condition gradually grew worse. She was not able to carry on any intelligent conversation, and her answers were irrelevant. She thought dead bodies were excavated and brought to life again. She imagined that her husband and the janitor of the house would kill her child. She had also an idea that the priest wanted to kidnap her son. She hated her husband, was not able to tolerate him, and had numerous delusions about him. On January 7, 1907, she was admitted to this hospital.

Upon admission here physical examination showed irregular and unequal pupils which did not react to light; deep reflexes active; knee jerks absent; heart and lungs without grave pathological lesions; no lymphocytosis of cerebro-

spinal fluid.

Mentally patient was quiet, complied with requests, made many remarks at random, used odd expressions, and gave expression to many obscene and meaningless statements. Her peculiar ideas and stream of thought may be illustrated

by the following answers to questions:

Is the janitress a murderess? "Yes, by all means; she was bringing girls in and colored men to do bad things, and they were all foreigners, and their old clothes and shoes were thrown out the back door." Did your husband try to poison you? "No, he never did—I had to receive him poisoned—he did not make any attempt to poison me —but I received him—he had been poisoned outside." How do you know? "I know it because of lack of eating, he was dragged in half drunk." What did they do? "You could hear them on the bed—those poor broken springs and you could hear them from one building to another—Mr. Van Start, 316 Sixth Avenue, sent his servant girl to take my child and I never would see it for a whole day, and he had no affection for me, but seeing that I was insane always had it on his mind, and sent me to the hospital. Two men came in to sit down in the evening with my husband, to sit down, to take me to Bellevue for nothing at all; it was a made up thing to take me away from my child."

Orientation: She gave the day as Friday (Wednesday), he month February, and the year 1907. The place she the month February, and the year 1907. The place she called "Parochial." Memory, retention, and general school

knowledge were much defective.

There were no important variations in her condition. She was quiet, inclined to be seclusive, never associated with her fellow patients, ofttimes resisted attention bestowed upon her, and upon several occasions manifested assaultive acts. Her speech showed affectation, frequently paused, and showed incoherence of thought. She expressed few ideas, which were dissociated and odd. For example: "The Pope educated her son to be a weaver-he got to new "The Pope educated her son to be a weaver—he got to new building on Thirty-seventh street, between Seventh and Eighth avenues, as sick as a weaver." "An Italian boy kicked up a weary glue." "You must transfer me to Thirty-seventh street, where I was married by Father Keane at the compulsion of the Pope." She stated that the Pope ordered her child a college education; he (her son) had two golden medals, and therefore the Christian brothers had become jealous of him. Since her child left school he had a touch of insanity; he took medicine which contained poison—morphine. The baker's girls took her husband away. The Pope sanctioned this marriage in spite of the fact that it was very well known to him that her husband away. The Pope sanctioned this marriage in spite of the fact that it was very well known to him that her husband had a wife. There are girls, in a ward, who belong to the baker's family; one of them screams out, walks to and fro and "demands evolution or support." Her son lost all his affection for her because he went among strangers. When she came here she was sane, but in this place she was driven to insanity. She suffered from a slight attack of despondency. She told the doctor: "I want you to take the same place from where me to my husband and son to the same place from where you took me out; if they are not there you must take me to St Francis's house, East Seventeenth street, and I will remain there till I find my husband and child. If they are dead then you have nothing to do." Mood is that of irrita-

Prove It is asserted by various authors that

prison confinement is a paramount cause for dementia præcox. Kraeplin offers this explanation: "The striking activity of prison confinement, which belongs to this group (dementia præcox), is difficut to explain. It is possible that the absence of light, fresh air, and activity, the uniform diet, and emotional influences may come in question." Three per cent. of his cases, or six per cent. of the men. developed this disease in prisons.

In Manhattan State Hospital, patients are not received from penitentiaries save from the Work House. The latter supplies most of our alcoholic cases. Only in two of my patients (one is not included in this series) dementia præcox developed during their imprisonment. Both of them were committed for vagrancy and alcoholic indulgence was out of the question. Paranoiac trend was marked in both cases, and deterioration in one especially was rapid.

Infectious Diseases and Operation.—In four patients dementia præcox followed infectious diseases —pneumonia in one; grippe in the second; measles and pneumonia in the third; typhoid fever in the

In two cases minor operations (such as operations for adenoids and hæmorrhoids) were supposed to be determinants. From ten to eleven per cent. of Kraepelin's cases resulted from infectious diseases.

Emotional Influences.—Emotions occupy a lofty position in the life of an individual. Ribot says: All forms of the creative imagination imply elements of feeling." "All emotional dispositions whatever may influence the creative imagination." He further adds: "I challenge any one to produce a solitary example of invention wrought out in abstracto, and free from any factors of feeling. Human nature does not allow such a miracle. also emphasized that "the essential foundation of our personality is affectivity. Thoughts and actions are expressions of our emotions. The component elements of psychical life are sensations, concepts, and feelings, which form certain units in our consciousness. These units may be compared to the molecules in chemistry. The ego complex is a psychological expression of the firmly associated paths of all the bodily subjective sensations. Each individual molecule of the complex takes an active part in our emotions; it can awaken our emotions and its complexes. The trend of our imagination can be interrupted by an affective idea."8

From this it will be readily seen how a marked emotional upset is liable to cause a mental alienation. In Kraeplin's eloquent phraseology: "Fear before an approaching misfortune, fright over an unexpected occurrence, anger over injustice, despair over sustained loss-these are powerful sudden concussions which displace our mental equilibrium, and these relatively frequent causative factors act as agencies in the profound, long, and continuous disturbances.

It is well known that in dementia præcox emotional upsets are considered important determinants. Thus in forty-nine of my cases (about thirty-eight per cent.) various affective conditions influenced the development of the psychosis. For instance: Worry over death of a parent, sister, or

brother; worry over mother's sickness; love affair; betrothal; marriage; attempted rape; fright; the disappearance of a son; financial loss; domestic infelicity; unhappy matrimonial life; lowering of social position; nostalgia, etc., etc.

Of these forty-nine patients, twenty-six showed both psychotic traits and heredity; in nine only psychotic traits; and in ten only heredity were demonstrated; in four no heredity or psychotic

traits were ascertained.

No Exciting Determinants.—In forty-two patients no definite exciting causes could be elicited. must be borne in mind that in these patients twenty showed both psychotic traits and heredity, eight gave a history of heredity, and twelve of psychotic traits, while in two no heredity or psychotic traits were determined.

We assume too much liberty in affirming that the mental disorder was produced without exciting causes. These patients' environment was bad, economic condition poor, and in general they were deprived of the sunny side of life. Also the psychogenic factors must not be forgotten. There are numerous incidents in one's life which may be potent stimuli in bringing about mental unbalance.

Abrahams in a recent paper discusses sexual trauma in adolescence and its relative significance in dementia præcox. Although he does not think that such conditions may cause the disease, yet he holds that the clinical phenomena are greatly modi-In one of my patients a psychosis suddenly developed without any premonitions. No particular cause could be satisfactorily established. Yet a thorough psychopathological analysis revealed a submerged complex which was the source of irritation. Long before marriage she gave birth to an illegitimate child, and this painful incident continuously and continually preyed on her mind.

Another extremely interesting case came recently under my observation (this is not included in my

series):

CASE XI.—The patient is an American woman, thirtyseven years of age, springs from an alcoholic parent, and her paternal third cousin suffers from insanity; she was always of a retiring disposition, unnaturally modest and bashful, uneven tempered, over religious, and not permitted to go out in the dark in fear of being assailed by men. She had no love affairs, was never married, and led an up-right life. For the past five years a characteristic change in her disposition was observed. She commenced to show incapacity for employment and delusions and hallucination of an erotic content developed. Upon her admission to the hospital she revealed a considerable degree of deterioration, peculiar to a dementia præcox reaction. From her mother we could learn nothing regarding the exciting cause of her mental malady, but from the patient, through the aid of psychopathological analysis, it was possible to establish a definite actiological factor for her psychosis. When interviewed patient spoke coherently, appeared pleasant, at times screwed the left side of her face, and

She declared that she had thoughts of an obscene character. She imagined that she perceived male organs, at times the act of sexual intercourse and libidinous attitudes. times the act of sexual intercourse and libidinous attitudes. While looking at any object, an obscene representation came before her mind. Even in church she associated holy pictures with erotic symbols.

She was pressed for information as to the mode of development of these peculiar ideas and after considerable questioning and cross examination, the following account

was obtained:

About fifteen years ago, while on her way to work, a man

exposed his genitalia to her and she was then very much rightened. As she put it: "I was as white as a paper; was much upset, could not speak from fright; when I came to my place of business, I told the girls about this shameful occurrence, and then I related it to my mother." Every time she passed that place she would think about the man's indecent act.

Ever since then lustful concepts would force themselves upon her mind. For the first five years they were not so intense, but for the last ten years they were extremely annoying to her. Ten years ago, on account of these evil imaginations, she became very nervous, cried frequently, at times, staggered, and finally decided to go to a doctor and later to the confessor. However, neither of them did

her any good.

For the past ten years she conceived the idea that people applied to her derogatory epithets. (This symptom she explains by saying that people were able to read her mind; hence, they found out her obscene imaginations). They would say: "She is a bad woman—a whore—a bum—a fast woman—a merry widow, etc." Not infrequently she would respond to them. These uncomplimentary comments became more aggravated for the last five years

For the past seven years she had often dreams of a sexual nature—that she was pregnant, or gave birth to a

child, etc.

Such hidden complexes are many, but not in every instance can they be divulged. Our present psychopathological investigations are far from being perfect enough to enable one to invade the mysterious realms of the human mind. "The general principle is that many individuals," says Adolf Meyer, "cannot afford to count on unlimited elasticity in the habitual use of certain habits of adjustment; that instincts will be undermined by persistent misapplication, and the delicate balance of mental adjustment and of the mental substratum must largely depend on a maintenance of sound instinct and reaction type." "Mind, like every other function, can demoralize and undermine itself and its organ, and the entire biological economy, and to study the laws of the miscarriage of its function and life is one of the conditions for any true advancement in psychopathology."

CONCLUDING REMARKS.

The limited material at hand does not permit one to offer conclusive deductions. However, it must be accentuated that heredity and constitutional make up enter as important ætiological factors in the evolution of dementia præcox. In sixty-four per cent. of my cases the former predominated, and in sixty-eight per cent, the latter was present. In addition to these there were determinants which materially aided the precipitation of the mental breakdown. In only thirty per cent. of my patients definite exciting causes were not satisfactorily Yet there were other conditions which undoubtedly had a significant bearing upon the cases. For instance, poverty, deficient sanitation, domestic infelicity, and environmental influences.

Although these facts demand our careful attention, yet it must not be forgotten that after all constitutional predisposition underlies dementia præcox, and its active symptoms can be precipitated by such exciting causes which react on the individual according to his peculiar temperament and idiosyncrasy. In speaking of dementia præcox, Bleuler says: "Perhaps here comes in consideration not

[&]quot;It should be somewhere I that Freud's essemble includes or Jung's association test is not available in every case of dementia

only the disease process, but also the morbid predisposition upon which no special disease process or novum was necessary to bring forth the symp-. . . The complex has no peculiar ætiological significance for the disease or disease process. Its effect consists in determining the symptoms. . . . So through the approach of an affect can a latent dementia præcox become manifest." And Jung formulates the following hypothesis: "Like any psychical cause, so can also an influence of an affect loosen the organic process of dementia præcox (through toxines) and indeed analogous to the manifestation of tuberculosis in a contused The disease develops in a locus minoris resistentiæ, that is, in dementia præcox the entire physical like the psychic disease process can develop from an affective complex, exactly like under any other conditions from a psychical trauma, infection, etc. If the complex was not in such a case, then the peculiar disease would not develop under these circumstances. Therefore for such cases the complex had not only the usual determinant, as far as its content is concerned, but also a significance for the origin of the organic process."

In this connection, perhaps, a question may be asked, How should the alienist view this enormous, continuous, and continual increase of insanity, and especially the deteriorating forms of mental diseases to which the great group of dementia præcox belongs? It should be borne in mind that out of three hundred inhabitants one is either insane or feeble Is it Nature's method to get rid of the undesirable product? "Do not let us say," tells us Adolf Meyer, "that this is merely one of Nature's methods of weeding out the unfit. Among the 25,-000 persons who are to-day in the public and private institutions of New York State alone, there are many brilliant hopes buried, largely owing to a lack of knowledge of what some people need in the way of social and personal hygiene. Remember that some of the most illustrious members of the race have been dangerously near the borderland of insanity and seem to have been great, although they showed obvious traces of the same misled instincts that have completely wrecked others. Are such people not worth our help? Should not the home, the press, and school mind some of the dangers and shape their ethics and methods accordingly

"This is the practical lesson to be drawn from the theory of degeneracy which is spread into the imature minds as a doctrine of fatalism, so that even high school pupils excuse themselves in some such a way as: 'I can't help this. It is hereditary in my family.' Part of this may be sadly true, but this is the duty of pædagogy and psychiatry to distinguish what is to be accepted with fatalism from what is open to correction. We have faith in gymnastics for the correction of physical defect. Let us devise more efficient gymnastics which lead us to heartily enjoy actuality, to instinctively shrink from antisocial ideas and abnormal friction, and to get time for an unsophisticated growth."

The rationale of modern therepeutics is the creation of prophylaxis. And in mental diseases preventive medicine is far more important than the actual treatment of psychical infirmity. Unfortu-

nately the establishment of prophylactic measures in insanity is outside of the régime of the alienist. We can warn the patient's relatives what steps to take in order to avoid an attack of mental alienation, but the state of affairs of our present society is opposed to the execution of the physician's orders.

Nowadays the struggle for economic independence, social distinction, and intellectual attainments tends to cripple the mental health of mankind. Professor Giddings emphasizes that "mutual aid is the foundation of economic organization and political alliance." Alas, this splendid theory, outside of its theoretical interpretation and endorsement of the Utopian philosopher, has no relative significance in our industrial society.

Pædagogy has made wonderful progress. Our teachers, in addition to a liberal education, must be thoroughly versed in the philosophy of Pestalozzi, Fröbel, Rousseau, Mann, etc.; they must possess a profound knowledge of psychology, and be carefully trained in the science and art of teaching. Yet despite all that the educational systems are defective. Child's turn of mind is misdirected. Goethe exclaims: "If children grew up according to early indications, we should have nothing but geniuses. This is somewhat too farfetched. One may say: Recognize and individualize child's propensities, exclude morbid and unnecessary stimuli; then abnormal psychic tension will be reduced to a minimum, and environmental psychoses and neuroses could be obviated to a great extent. The curricula of studies should be adopted according to the individual needs of our pupils and not vice versa. Each school should have a competent psychiatrist. The stubborn, cranky, nervous, malicious, backward, etc., should be brought to the physician's attention, and such unfortunate pieces of humanity should be subjected to early medical correction.

Again to quote Dr. Adolf Meyer:

I should urge that we spread among teachers and pupils a realization of the fact that knowledge must be a knowledge of doing things, and next a knowledge ready for doing things. Even in cultivating the instincts of play and pleasure we must aim to make as attractive as possible those games and diversions which require decision and action and carry with them a prompt demand for correcwith others and for others, and not the play of mere rumination. We further must aim to find levels of activity with moderate demands and well within the limitations of even the less brilliant or less vigorous children and yet giving full enough satisfaction to remain attractive and truly stimulating. . . . It is evidently the plain duty of those who have to map out curricula and those who have to advise as to the life of children who are in danger, to see that the doing of things is made infinitely more attractive than is usually the case. I do not see why the success of efforts directed toward this object should not appear more glorious than, or at least as glorious as, the devising of some new plan of cramming the pupil with the subjects of a conventional curriculum. Thus it is that through training in wholesome action as well as in physical culture a real hygiene is making its way into the schools. At the same time, a more careful study of levels of capacity and of ways of making the easier levels sufficiently attractive and full of meaning, may well become a matter of serious cooperation between the pedagogue and the psychopatholgist.

Unless the social reformer, sociologist, educator, and physician will cooperate and work together to-

ward the readjustment of the dissociated strata of our community, insanity will remain on the increase, and prophylaxis in mental diseases will be the theoretical speculation for the dreamer!

SARCOMA OF THE SMALL INTESTINES, WITH THE REPORT OF A CASE.*

By John A. McGlinn, A. B., M. D., Philadelphia,

Assistant Professor of Gynacology in the Medicochirurgical College; Gynacologist to St. Agnes's Hospital.

Sarcoma of the intestines is a rare condition. A study of the textbooks on pathology and surgery shows that, except for the mere statement of its rarity, they give scant space to the discussion of the disease.

Movnihan in Abdominal Operations, published in 1905, gives a résumé of all the cases of sarcoma of the small intestines, treated by operation, recorded up until that time. In all forty cases are recorded. L. G. Anderson in the British Medical Journal, October, 1907, reports an additional case, to which I

Read before the Frankford Branch of the Philadel his County Medical Society, October, 1908.

wish to add one, making a total of forty-two recorded cases.

The history of the case is as follows:

B. H., age eighteen; male; Italian; admitted to St. Agnes's Hospital, January 10, 1908. He has been in this country two months. Previous to his present illness he always enjoyed good health and was able to perform laborious work. Family history negative. One month ago he began having gastrointestinal symptoms; diffuse abdominal pain, nausea, vomiting, eructations of gas and constipation followed later by diarrhœa. Three weeks ago he noticed that his abdomen was enlarging. The enlargement developed very rapidly, and one week ago he consulted a physioped very raphily, and one week ago he consulted a physi-cian, who diagnosticated the case as one of ascites, due to tuberculous peritonitis. He performed paracentesis abdo-minis and withdrew about one quart of yellowish white, turbid fluid which he considered pus. The abdomen again refilled with the fluid one week later, when he was sent to the hospital.

On admission to the hospital the patient complained of diffuse pain over the abdomen. There was no spot of localized pain or tenderness. The stomach was unretentive, and he had frequent diarrhecic stools. The abdomen was greatly distended and contained free fluid. The temperature was septic in type, ranging as high as 104° F. He was emaciated and anæmic, though the cheeks were flushed. Profuse cold sweats were present at night. I concurred in the diagnosis of tuberculous peritonitis, and as the heart and lungs were negative advised abdominal section under a general anæsthetic

The patient was operated upon three days after his admission to the hospital. On opening the abdomen a large quantity of milky white fluid escaped. A specimen of the fluid was sent to the laboratory for examination, but owing to the absence of the regular pathologist an incomplete and unsatisfactory report was returned. All the definite information gained was that the fluid was not pus. I have no doubt from the character of the fluid that the case was one of chylous ascites. After the fluid was evacuated and the abdominal contents came into view a most unusual picture presented itself. The great omentum hung down over the intestines like a bright red curtain. At the bottom of the incision, showed a tumor mass which closely resembled a uterus, gravid at seven months. This mass subsequently was found to be the bladder. The omentum had entirely changed in appearance. There was no fat to be found and no vessels were visible. It was bright glistening red in color, smooth and about three-quarters of an inch in thick-

Pushing the omentum up toward the diaphragm the intestines were brought into view. All the intestines, both large and small, had the same general appearance as the omentum. On endeavoring to bring the intestines into the wound they were found to be firmly fixed in the abdominal wound they were found to be firmly fixed in the abdominal cavity. The mesentery was then examined and found to be also involved in the process. The mesentery was of the same general appearance as the omentum, and was about one-half inch in thickness. There was no evidence of involvement of the glands. The intestinal walls felt to be about one quarter inch in thickness and were uniformly thickened throughout their entire length. The bladder was pear shaped, the walls were about one-half inch in thickness and the owner half the owner had the appearance and feel of a present ness, and the organ had the appearance and feel of a pregnant uterus. The liver, spleen, and stomach were appar-ently not involved in the process. There was not a sem-blance of a tumor mass, nodule, or even an adhesion any-where in the abdominal cavity. All the organs involved seemed to be symetrically thickened. The abdomen was closed in layers.

The postoperative history was without any complications, due to the procedure. The abdomen rapidly refilled with fluid, the patient gradually became weaker, and died on the tenth day. A post mortem examination could not be secured. A small piece of tissue was removed at the time of cured. A small piece of tissue was removed at the time of the operation, and I am indebted to Dr. A. O. J. Kelly, who studied the specimen and submitted the following patho-logic report: "Microscopically the tissue consisted of rather large round cells that were fairly uniform in size and had large well staining nuclei and a moderate amount of protoplasm. The intercellular substance was scanty. The bloodvessels were moderate in number; some of them were dilated, and their wall for the most part consisted only of endothelium. The appearances conformed, therefore, to those of a large, round cell sarcoma."

While waiting for the pathological report the case was submitted in detail to a number of well known pathologists, who were unable from the description given to recognize the condition. From a study of all the cases of sarcoma of the small intestines treated by operation which have been roorded, and the subject of sarcoma in general, I have been unable to find a counterpart of this case.

A study of this rare condition in the forty-two recorded cases is of interest. It may occur at any age. The earliest case reported was that in a boy, fourteen years old, and the latest in a man of sixty-two years of age; five cases occurred between the ages of ten and twenty; eight cases between twenty and thirty; ten cases between thirty and forty; thireteen between forty and fifty; five cases between fifty and sixty; and one case occurred after sixty.

Twenty-three cases, or fifty-six per cent, occurred between the ages of thirty and fifty. This might be supposed to be the age of greatest frequency of the disease, but inasmuch as the total number of cases recorded is so small I hardly think this inference would be of much value.

Sex apparently has no influence on the disease. It occurred in twenty-two males and twenty females. This is in contradistinction to carcinoma of the intestines, to which disease the male sex seems

to be particularly susceptible.

From the incompleteness of many of the reports it is impossible to draw any conclusions as to the relative frequency of involvement of the different parts of the intestines. In the forty-two cases recorded sixteen are reported as involving the small bowel. No information being given as to the particular portion involved. Of those cases where definite information is given we find the duodenum the seat of the disease in one case; the jejunum in eleven cases; the ileum in thirteen cases; the ileum and cæcum in one case; and general involvement in one case. From these figures it would seem that all parts of the bowel except the duodenum are equally susceptible.

In thirty-nine cases a distinct tumor mass was found varying in size from an egg to an adult head. In two cases small nodules of lymphosarcoma were present, and in one case uniform thickening of the

walls of the gut.

Practically every variety of sarcoma has been recorded as being found. In four cases the pathological diagnosis is given simply as sarcoma. These cases were probably of the round cell variety, as it is likely, had they been of the more infrequent forms of the growth, they would have been so specifically stated. The following varieties are recorded: Lymphosarcoma, five cases; spindle cell sarcoma, seven cases; sarcoma (variety not specified), four cases; round cell sarcoma, nineteen cases; myxosarcoma, one case; myxosarcoma, three cases; alveolar sarcoma, two cases; and fibrosarcoma, one case.

The round cell variety is the most frequent, occurring in forty-five per cent. of all the cases, and if we include the four cases where the variety was not specified it occurred in fifty-five per cent.

Sarcoma of the intestines has no pathognomonic group of symptoms. Abdominal pain may be present, in some cases dull, in others sharp or colicky, in some diffuse, in others localized, in some con-

stant, in other paroxysmal, in some coming on acutely, lasting but a short time, in others lasting for months or even years. Nausea and vomiting are frequent, though they may be entirely absent during the whole course of the disease. Constipation is the usual rule, though in some cases diarrhœa may be present from the beginning. In many cases there are symptoms of chronic obstruction, while in others acute obstruction is the first condition noted. In some cases there was an entire absence of symptoms except the presence of a tumor. A distinct abdominal tumor was noted before operation in thirty-nine of the forty-two cases. two cases, one reported by Lecene in Thèse de Paris, 106, in 1904, and in my own case ascites was noted. Fever may be present, particularly in the disseminated lymphosarcomas. Emaciation and anæmia are usually present late in the disease.

It is impossible to make an exact diagnosis until the growth has been studied at operation or microscopically. The presence of a tumor with wasting and anaemia will of course indicate malignancy, but a benign growth causing chronic obstruction will present practically the same symptomatology. In the differential diagnosis it is well to remember that carcinoma of the intestines occurs usually after fifty years of age, and is much more frequent in

males than in females.

The prognosis without operation is of course practically always fatal. No definite time can be fixed for the limit of the disease. Most cases die within one or two years, though one case is recorded as having presented symptoms for nine years previous to operation. Many accidents may intervene to shorten life. Thus in one case reported by Libman death occurred in twenty-four hours after the onset of acute symptoms as the result of perforation and general peritonitis. In two cases intussusception was found, in three cases absolute obstruction, and in one case metastasis to the liver and spleen.

Treatment.—The presence of a tumor in the abdomen calls for surgical intervention and an exploratory section should be made and the patient treated according to the operative findings. In the present series nine of the cases were judged to be inoperable and the abdomen closed without any attempt being made to cure the condition. In one case of obstruction enterostomy was performed, followed later by a resection of the bowel with the cure of the patient. In thirty-three cases resection of the affected portion of the gut was practised. In thirty-two end to end anastomosis was performed, and in one lateral anastomosis.

The operative death rate from all causes excluding recurrence was nineteen. Five patients had recurrence, a total death rate of twenty-four, or fifty-seven per cent. Eighteen cases, or forty-three per cent., are reported cured. When we consider the death rate of resection for obstruction, varying from thirty-five per cent. to ninety per cent., depending on the length of time the obstruction has existed, the mortality in this condition cannot be held abnormally high.

The variety of tumor apparently has no effect on the rate of death, recurrence, or cure.

Death occurred with lymphosarcoma in three cases; spindle cell sarcoma in two cases; round cell

sarcoma in eight cases; sarcoma (unspecific) in two cases; myosarcoma in one case; and alveolar sarcoma in one case.

Recurrence occurred with round cell sarcoma in three cases; myosarcoma in one case; and alveolar

sarcoma in one case.

Cure resulted with round cell sarcoma in seven cases; spindle cell sarcoma in four cases; lymphosarcoma in two cases; myxosarcoma in one case; sarcoma not specified in two cases; myosarcoma in one case; and fibrosarcoma in one case.

113 SOUTH TWENTIETH STREET.

MALARIAL FEVER.

With Report of Three Cases, Comatose Form. Statistics Showing Relative Blood Findings in Malarial Infection in the States and in the Tropical Zone. Also Some Statistics Collected from Charity Hospital.*

> By J. Fred Dunn, M. D., New Orleans.

Malarial fever is an infection characterized by:
(a) Paroxysm of intermittent fever of quotidian, tertian, or quartan type; (b) a continued fever marked with remissions; (c) certain pernicious, rapidly fatal forms; or (d) a chronic malarial cachexia with anæmia and enlarged spleen. (Osler's

Practice of Medicine.)

We know that this infection is caused by a microorganism, or parasite, the *Plasmodium malaria* which is transmitted from an infected person to a healthy individual by the anopheles mosquito. Histologically we go back as far as the nineteenth century when Peruvian bark was discovered, and we find that, therapeutically, malarial was distinguished from other forms of fevers by Morton and Torti. Before then, malarial and other fevers were all massed together. If we go back still further, however, we find, in the writings of Hippocrates, fevers described which resemble malarial fever.

A. Meckel, in 1847, found pigmented corpuscles from the spleen of a patient dying with malarial infection, and also in the blood. Virchow afterwards confirmed this observation. Planer discovered the presence of these pigmented corpuscles in fresh blood, and his theory was later confirmed by the writings of Frericks and Kelsch. Laveran, in 1877, began a series of experimental research works and, in 1880, he described the various aspects assumed by these pigmented corpuscles, or malarial organisms, and, in 1885, Golgi observed that with the sporulation of these organisms, the paroxysm of fever took place. Among others who have contributed to the study of malarial fevers are: Thayer, Heweston, Osler, and James.

The mosquito theory was advanced by Ross, and also Grassi and Bignami. Regarding this mosquito, we are told that it is the anopheles family that transmits the disease, by carrying the infection from an infected person to a healthy individual. They are recognized by their position, when in a sitting posture, either perpendicularly or at an angle, and by the aid of the microscope we find spotted wings; well marked spots on their piniris, or claviger, four

spots in all; their proboscis and palpi are of the same length; there are three varieties of the anopheles.

In man, the cycle of the plasmodium begins with a spot seen in the red blood cell, toward one side and showing a ribbon like appearance and amœboid. As development goes on granular matter begins to show, having at first a peripheral arrangement, and increasing as the hæmoglobin is destroyed. As development goes on, this granular matter goes towards the centre, and is found there when segmentation sets in. The spot first seen increases in size and becomes less motile, almost filling up the corpuscle. Signs of life are now visible, and thin lines are seen between these segments, or points of life, on the plasmodium. When the corpuscle bursts its covering, these spores attack other red cells and begin a new cycle. The coloring matter, or pigment, is thrown into the blood, and sometimes attacks the leucocytes.

From the histological readings, we learn that the paroxysm of fever is coincident with the sporulation, which throws out toxines causing a depression of the vasomotor centre, which causes the chill seen

in malarial fever.

The microscope shows the different forms of the malarial plasmodia, and we find that some do not segment, and these are known as extracellular; while some throw off a flagellum from the granular process, and these flagella are supposed to be the

male elements.

When the mosquito sticks his proboscis into an infected person, he sucks up these different forms of plasmodia, and the flagellum, or male element, impregnates the extracellular bodies, and fecundation takes place inside the stomach of the mosquito. Spores are thrown off which pass into the walls of the stomach, and in the muscular coat begins a development somewhat similar to that in man. When the development is complete, these bodies burst their coverings and these sporozooids are thrown into the cavity and escape, through the salivary glands of the mosquito, into the ducts which are inoculated, and are carried into the human blood by the bite of the mosquito.

Having seen that the anopheles transmit these parasites, we should look toward the destruction of this species of mosquito, and with proper measures try and kill them, thereby preventing the transmission of this widely distributed infection.

To begin a crusade against this mosquito, what

s needed

Educate the public; have honest legislation; and then we can easily do the work; drainage to clear up the swamps, and prevent the breeding of this mosquito; teach the public the laws and rules of hygiene and sanitation; have the legislature pass these laws and appoint officials, who are honest, to see that these laws are carried out.

As to the distribution of malarial infection, a point of interest may be mentioned, in stating that as far North as 64° (in Finland), cases have been reported. In the United States, the disease is more prevalent in the southern States, while the northern States show a scarcity of infection; the central States seem free from it, and in the northwestern States it is not known.

^{*}Graduation thesis, Class 1908, medical department, Tulane University of Louisiana

The Central American countries are filled with malaria, and of a marked type, as I have noticed in my observations of the blood, and especially the anæmia and debilitating effects produced on the

system.

· The infection is at its maximum in the spring and autumn months. While we do not find a very high mortality, or death rate, perhaps if we would only follow the patients, whose systems have been ravaged by the infection, we would find that there was such a marked lowering of vitality, or resisting power, left, that the system was an easy prey for tuberculosis, pneumonia, rheumatism, etc., and we could then understand that over thirty per cent. of all deaths caused by, or attributed to, these diseases, could be primarily placed at the door of malarial infection. With this in mind, we should easily see that, even though we know that quinine destroys the parasite in the blood, and change in climate, etc., helps the individual, our real great effort should be toward the prevention of the transmission, by killing the anopheles.

I will now report a few cases that came under my observation and treatment in the wards of the Charity Hospital, during the months of October and November; also a case that was treated in the country during the vellow fever epidemic in 1905. In my personal experiences, I have had over forty cases of fever in these two months, and will give a short outline of the prevailing symptoms and blood findings, with some few statistics that I collected when I first began my work on the blood.

CASE I .- A case of malarial fever, from Colon; the patient was treated in the country, during the yellow fever epidemic, for yellow fever and later for appendicitis, but was finally given quinine and cured, thus illustrating some errors in diagnosis and showing the precaution taken in treating yellow fever in epidemics.

treating yellow fever in epidemics. Patient, white, male, had been in Colon during the month of August, and upon reaching New Orleans went out to the country. There was a yellow fever epidemic in the city and surrounding towns. Patient was taken ill suddenly, upon arriving in the country, and at 6 p. m. had 102° F. temperature, severe frontal headache, backache, constipation, and distended abdomen. He was at once put to bed, his case diagnosticated as yellow fever, on account of the epidemic; and he was screened and isolated, and given purgation and hydrotherapy.

Second day of illness showed temperature ranging be-tween 104° and 105° F., finally reaching 106° F. toward evening. There was no albumin in urine; patient appeared to be jaundiced, bleeding from the nose, and became de-lirious during the night. Ice pack for reducing the tem-

perature and no medication.

Third day. Temperature fell to 100° F.; patient was put in charge of trained nurses; the diagnosis of yellow fever being confirmed at a consultation, without having made a blood examination under the microscope. (See Temperature Chart 1 for course of fever.) Patient was nauseated, retched, abdomen distended, urine scanty and highly colored, no albumin; at 9 p. m. temperature 103° F.; pulse, 116. Ducro's clixir was given, one half ounce every three hours; vichy water p. r. n.; caffeine citrate, I drachm, every two hours; hydrotherapy; saline enema at night.

Fourth day showed a gradual rise in temperature. Pa-

Fourth day showed a gradual rise in temperature. Patient was restless, nauseated, and voided forty-five ounces of urine in twenty-four hours. No albumin. Hydrotherapy; acetphenetidin, five grains, when ice pack failed to reduce temperature. Other treatment continued.

Fifth day. Temperature had gone down during the night and began rising during the day, reaching 103° F. at 10 p. m. Urine showed no albumin; voided fifty-four ounces of urine; was constipated, stools were small and hard. Saline enema, hydrotherapy, stimulation, and liquid nourishment.

Sixth day. Temperature ranging around 103° and 104° F. Retention of urine; had to be catheterized and thirty ounces of urine withdrawn in twenty-four hours. Treat ment continued, and added mustard jacket to back over kidneys; hot application to bladder.

Seventh day. Change in temperature (see chart). Pulse began to grow weaker and irregular. Headache. Nauseated. Slight jaundice. Bleeding from the nose. Constipation. Catheterized every six hours. High saline enema. Bladder irrigated with boracic solution. Hydrotherest. therapy. Acetphenetidin, ture. Liquid nourishment. Acetphenetidin, 21/2 grains, to control tempera-

Eighth day. Still restless; nauseated; pains in abdomen, and abdomen distended; tympanitis marked, and expelling gas freely. Pulse rapid and weak. Trional, 10 grains, for restlessness; cocaine, ½ grain, to allay nausea; digitalis, m. v., and strychnine, 1/30 grain every four hours. Saline

and soap enema.

Ninth day. Vomiting; pain localized in right iliac fossæ; distended abdomen; constipation; weak and irregular pulse. Appendicitis was suspected, and a surgeon was called in, who pronounced the case malarial infection and sent the patient to New Orleans for treatment. Patient had hæmaturia, incontinence of urine, and fæces; adrenalin chloride was given coming down on train. Upon reaching New Orleans, patient was sent to a hospital and started quinine hydrochloride, 10 grains every two hours by injection, until three doses were taken, and then every four hours, regardless of hæmaturia. Liquid nourishment; hydro-

regardless of hæmaturia. Liquid nourishment; hydro-therapy, and catheterized every six hours. Blood examina-tion: Plasmodia malariæ (crescents). Urine: Specific gravity, 1.022; acid reaction; blood and albumin. Tenth day. Chilly sensations, coughing, retching, irrita-tion of throat, pulse very weak and irregular, ranging be-tween 102° and 104° F. Blood examination: 3,000 leuco-cytes, still contained crescents. Quinine continued by injection every three hours. Stimulation, and treated

symptomatically.

symptomaticany. Eleventh day. Profuse perspiration, resting quietly. Leucocytes, 4,200. Hæmoglobin estimate, 105 per cent. (?). Urine, acid, specific gravity 1.028; bile pigment and pus. Calomel, I grain, each hour, until five doses; folowed by Apenta, 3 ounces; enema at 12,30. Stimulation; quinine hydrochloride, grains 10, by injection, every four hours. Nourished as usual.

Twelfth day. Nauseated, retching, unable to take anything by mouth. Slight catarrhal condition developed; perspiring freely. Same treatment.

Thirteenth day. Discontinued quinine, and from them on patient began to improve. Abscess from hypodermic injection of quinine developed. Treated symptomatically. During convalescence patient was given tincture of iron

chloride, m x.; tincture of digitalis, m v.; and Fowler's solution, m v.; t. i. d., also nitrohydrochloric acid, m xv., t. i. d., after meals.

This case shows the great use of a microscope, and the results of quinine in malarial fever, as the patient was thoroughly saturated with malaria before injection of quinine was commenced.

The question might arise as to whether the attending physician was right in diagnosticating this case vellow fever, but when we stop and consider the symptoms and also that there was an epidemic of vellow fever at the time. I think we may state that the physician was justified in diagnosticating the case as vellow fever, and showed good judgment in taking all precaution; but he should have acknowledged his error after five days of fever, as the chart alone would tell him his diagnosis, and even though he had no microscope he should have given quinine.

Case II.—Illustrates a case of æstivoautumnal fever with coma, and is a case developed in the swamps of Louisiania. Treated personally in my ward at Charity Hospital.

White, male, aged thirty-nine, carpenter by occupation. Family history: Father had died with carcinoma, and

mother with phthisis.

Personal instory: Drinks, smokes, and chews. Had

measles and bronchitis when a youth. Gonorrhea fifteen

years ago, and chancroid at same time.

Present illness: It began with a chill, followed by high fresent liness: It began with a clini, tollowed by high fever, while working on Atchafalaya River near Lafayette, La, about ten days before admission. Pains in back and in chest. Constipation, presumably from drinking, because he stated that he drank "whisky and quinine" while in Lafayette.

This obtained from patient when he was convalescent. When seen by me patient was in a semicomatose state; temperature, 88° F.; pulse, 92; respiration, 24; delirious; unable to give any history, except that he was hungry and had nothing to eat. Could not tell where he resided; condition suggestive of many things; in fact, acting upon a suggestion that he was a "dope" fiend, attempted to find traces of same. From clinical aspects, case looked like malarial infection with coma, but the examination of the blood being negative, and having patient in a hospital, simply de-layed quinine and treated symptomatically, as will be seen

Physical examination on admission: White, male, emaciated, very anæmic, jaundiced, dazed, and stupid (semi-comatose), and delirious at times. Skin had a yellowish tinge, was dry and hot. Eyes were dull, listless, and had a stupid expression. Pupils were evenly contracted and reflexes present. Mucous membranes were pale and anæmic. reflexes present. Mucous membranes were pale and anæmic. Lips were dry and cracked. Teeth covered with tobacco stains and tartar. Tongue was dry, pointed, edges red, surface covered with thick brown fur. Foul odor to breath. Lungs showed slight bronchitis. Heart was apparently normal. Pulse of good volume, slightly rapid. Spleen was enlarged and palpable, very tender. Abdomen was not distended, but tenderness noted. Urine had a preside gravity of Vaz was evid showed trace of ellumin. specific gravity of 1.023, was acid, showed trace of albumin, but nothing else noted. Blood examination was negative. Marked leucocytosis. Neutrophiles, seventy-nine per cent.; small lymphocytes, ten per cent.; large lymphocytes, eight per cent.; transitional, three per cent.

On third day patient had a sudden rise of temperature from 99° to 103° F. at 8 p. m., following a severe chill; urine scanty, highly colored, no albumin; blood examination negative; patient comatose and delirious. Tempera-

ton negative; patient comatose and delirious. Temperature declined by crisis, reaching 98° at 6 a. m. Fourth day without any noticeable signs of chill; had a rise of temperature from 99° to 104° F, at 4 p. m. Again comatose, irregular and rapid pulse; irregular respiration; cyanotic; incontinence of fæces, loose and offensive stools; retention of urine. Blood, malarial plasmodia found (crescents in abundance). Began treating as comatose form of malarial fever, and patient passed out of coma on sixth day, about forty-eight hours after instituting quinine treatment, and from then on patient was convalenced. treatment, and from then on patient was convalescing. Hypodermic abscess developed later; patient was treated symptomatically

Treatment of case. Upon admission was put to bed after cleansing bath, and was given hot saline enema and diuretics, treating symptomatically and watching patient closely. Hydrotherapy for temperature. Began quinine when the bacillus was found, and gave quinine hydrochloride, 15 grains, by injection, every two hours until three doses were given. Diuretics, stimulating nourishment (liquids). Catheterized, etc. This was on fourth day

of admission.

Fifth day. Quinine hydrochloride, 10 grains, at 10 a. m., 12 12 m., and 2 p. m., by injection, repeating at 10 p. m., 12

m., and 2 a. m. Other treatment symptomatic.

Sixth day. Patient passed out of comatose state; given quinine, 10 grains, every four hours, and Fowler's solution, m. v., t. i. d. Discontinued quinine the next day, and began tonic treatment, iron, arsenic, and strychnine.

This case shows again the use of a microscope and the results of quinine. With a case of this kind, in private practice, I would not have hesitated,

but would have given quinine on the clinical aspect

CASE III.—This case illustrates another comatose condition, and, comparing the three cases, we can obtain a good deal of information, showing the severity with which malaria attacks the system and how saturated one can get when not treated properly. With a picture of these cases, clearly defined, one should never make an error in comatose malaria, and I would like to plead for a trial at quinine, when we find a patient presenting these symptoms, and having no definite diagnosis, even though the blood examination is negative.

Patient admitted from clinic to ward in a delirious condition. No history obtainable, except that he had been drinking heavily. Urine showed specific gravity 1.013, acid, and 2.5 per cent. albumin, with firely granular and hyaline casts. Blood examination was negative.

Physical examination. White male, emaciated, jaundice marked, very anæmic, strong odor of alcohol to breath. Face flushed. Delirious, very nervous, and in semicoma-Face flushed. Delirious, very nervous, and in semicomatos state. Eyes, the pupils were dilated equally, but reflexes present. Vessels mjccted. Sclera, yellow. Mucous membrane was pale and very anæmic. Lips were dry and cracked. Tongue, heavily coated with thick brown mass, and broad, dry, and swollen. Pulse was weak and irregular. Skin dry and hot. Nausea; yomiting; bowels loose and profuse and voiding involuntarily. In heart and lungs nothing, was noted. Supern was enlarged and nalpals. nothing was noted. Spleen was enlarged and palpable.

nothing was noted. Spleen was enlarged and palpable. On admission patient was put to bed, after cleansing bath, and given alkaline diuretic, hot saline enema, and stimulation, treating symptomatically. On second day of admission hyalin and segmenting forms of malarial plasmodia were found, and at once began quinine, starting with fifteen grains or thirty minims of quinine hydrochloride, by injection, every two hours until four doses were given, and injection, every two hours until four doses were given, and then ten grains every four hours, hypodermically, until patient became conscious, fifty-two hours after first dose of quinine. Also gave stimulation, hydrotherapy for temperature, alkaline diuretics, and feeding by rectum. When patient became conscious, and during rational periods, he stated that during the past five weeks he had been working in swamps and had contracted malarial fever, taking quine at different times, but would continue to have irreducing the state of the contraction of the contrac in swamps and not contracted mataria fever, taking qui-nine at different times, but would continue to have irregu-lar chills and fever, and, reaching New Orleans about three days before admission. began drinking heavily. Fifth day. Patient was completely rational, showing improvement; from then on he continued to improve, until

discharged.

Blood showed forty per cent. hæmoglobin and distinctive leucocytic counts; neutrophiles, sixty-two; small lymphocytes, eighteen; large lymphocytes, sixteen; and transi-

(Charts for each of these cases will be found at-

tached to this paper.)

These three cases were all reported as comatose form, and two were from the swamps surrounding Louisiana, and one from Central America. In the examination of malarial blood, I was surprised at finding a difference in the lymphocytosis, and began a series of blood examinations. I would like to report said findings in the distinctive leucocytic counts, as made by me from these cases.

Malarial fever contracted in Louisiana, patients never having been in any Central American port,

blood findings as follows:

Tertian form of plasmodia found in the following twelve cases, with distinctive leucocytic counts in percentage as follows:

| | | . 2 | 3 | 4 | 5 | 6 | 7 | 8 | 2 | 10 | 1.1 | 1.2 | Average. |
|-------------------------|-------|-----|-----|-----|-----|-----|-------|-----|-----|-----|--------|------|----------|
| Neutral tiles | 5.4 | 6.5 | 6.8 | 63 | , | 60 | 68 | 5.5 | 7.1 | 65 | 50 | -: | 0,3 |
| Large lymphocytes | | 1 5 | | 1.0 | | 14 | 10 | 1.4 | 8 | 1.0 | 1.4 | 0 | TT |
| Small lymphocytes | | 16 | t a | 1.4 | . 5 | 26 | 18 | 20 | 23 | 2.2 | - 5 | :8 | 21 |
| Transforal | | 1 | | = | | | 3 | 3 | 2 | 2 | 1 | 2 | 2 |

| | _ | | | | - | _ | - | | | _ | - | www. | _ |
| | 7 344 | 100 | 100 | 100 | 100 | 100 | 2 3/1 | 100 | 100 | 100 | 2 + 17 | 2000 | 99 |
| Hæm el hin estem te, ir | | | | | | | | | | | | | |
| per cent | | , 9 | 15 | 0.0 | 58 | 70 | 65 | 58 | | | | 24 | |

In Case III, where we found twelve per cent. eosinophiles, the fæces were examined and no ova uncinaria found.

The following eight cases were æstivoautumnal variety from the swamps surrounding Louisiana, showing percentage in distinctive leucocyte count as follows:

| | | | | | | | | | Aver |
|-------------------|-----|-----|-----|-----|---------|-----|-----|-----|------|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | age. |
| Neutrophiles | 50 | 62 | 5.5 | 49 | 79 | 65 | 58 | 52 | 58 |
| Large lymphocytes | 18 | 16 | 18 | 13 | 10 | 16 | 15 | 18 | 15 |
| Small lymphocytes | 24 | 18 | 27 | 28 | 8 | 18 | 20 | 25 | 21 |
| Transitional | 4 | 4 | | | 3 | 1 | 5 | 3 | 2 |
| Eosinophiles | 4 | | | | | | 2 | 2 | 1 |
| | _ | _ | | _ | 49-11-2 | _ | | | - |
| | 100 | 001 | 001 | 100 | 100 | 100 | 100 | 100 | 97 |
| Hæmoglobin esti- | | | | | | | | | |
| mate in percent. | | 40 | | | 30 | | | | |

Cases II and V are the two comatose cases reported before.

The following six cases all came from some tropical port, either Panama, Colon, Central America, or Spanish Honduras. The first six showed the tertian form of plasmodia, and counts reported as follows in per cent.:

| | 1 | 2 | 3 | 4 | 5 | 6 | age. |
|----------------------|-----|-----|--------|-----|-----|-----|------|
| Neutrophiles | 63 | 62 | 59 | 40 | 55 | 48 | 5.4 |
| Large lymphocytes | 13 | 16 | 8 | 4 | 10 | 9 | 10 |
| Small lymphocytes | 18 | 20 | 33 | 47 | 3.2 | 39 | 3 1 |
| Transitional | 1 | | | | 1 | 2 | I |
| Ensinophiles | 4 | 2 | | 7 | 2 | 2 | 2 |
| | _ | - | Allena | - | - | _ | _ |
| | 100 | 100 | 100 | 100 | 100 | 100 | 98 |
| Hæm-globin, per cent | 48 | 45 | 40 | 30 | 40 | 45 | |

Case IV, having an eosinophilia, fæces were examined, but no ova uncinariæ found. In these reports, we see for the first time, an increase in the small lymphocytes.

The following nine cases were all from some tropical port, and blood showed æstivoautumnal parasite:

| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | age. |
|--------------------|-----|-----|-----|-----|-----|------|-----|-----|-----|------|
| Neutrophiles | 29 | 45 | 4.7 | 37 | 5.2 | fs i | 4.5 | 38 | 35 | 4.3 |
| Large lymphocytes. | 27 | 6 | 2 | 8 | - 8 | 7 | 8 | 8 | 0.1 | 9 |
| Small lymphocytes. | 43 | 44 | 49 | 5.5 | 38 | 3.1 | 35 | 52 | 50 | 4.3 |
| Tran-itional | - 1 | 1 | | | | | 2 | 2 | 3 | 1 |
| Eosmophiles | | 4 | 2 | | | 1 | 10 | | 2 | 2 |
| | | | _ | _ | - | - | | - | - | _ |
| | 001 | 100 | 100 | 100 | 100 | | 100 | 100 | 100 | 0.8 |

Case VIII was from Puerto Rico, and ova uncinaria were found in the fæces. In this last report we find a marked increase of the small lymphocytes, and in comparing the two classes, those from the tropical ports and those from the States, the lymphocytosis is marked in one with a small lymphocytosis and a slight increase of the large lymphocytes in the other, as the report shows.

In regard to symptomatology, I noted the following: Out of forty cases treated in my service. thirty-six patients had chill followed by fever, and four did not have any chill; thirty-two had severe headache, and eight no history of any pain at all; twenty complained of pains in back and other parts of body. Onset was sudden in thirty-four cases. Tongue was coated, swollen, moist, and foul odor to breath in twenty-eight patients. Nothing noted in ten patients, and two cases reported as dry, pointed, and thick, whitish fur on tongue. Eyes: Sclera yellowish, and jaundice noted in twenty cases; twelve having nothing noted, and eight with watery and injected eyes. Mucous membrane pale and very anæmic in nineteen cases; pinkinsh and healthy in twelve cases, and nothing noted in nine cases. Skin had a yellowish tinge in twenty cases; dry and hot in twenty-five cases. Urine showed febrile reaction in thirty-four cases; nothing noted in six cases. Bowels were constipated in thirty-one cases; diarrhœa in seven cases, and nothing noted in three cases. Pulse was full, bounding, and rapid in 25 cases, but pulse was generally in ratio to fever. Fever in twenty-five cases was above 104° F. on admission; in twelve cases was between 99° and 100° F. Fall of temperature in all cases was followed by profuse perspiration. Spleen was enlarged and palpable in thirty-one cases, and also tenderness noted in twenty-eight cases out of these thirty-one. In nine cases spleen was not palpable.

The following diseases were associated with malarial infection, out of forty cases treated:

Acute bronchitis in four cases; chronic bronchitis in two cases; pulmonary tuberculosis in five cases; pneumonia in one case; alcoholism in six cases; delirium tremens in one case; acute gastritis in one case; dysentery in one case; conjunctivitis in two cases; pharyngitis in one case; orchitis in one case; gonorrhoa in five cases; uncinariasis in one case; acute fibrinous pleurisy in one case; chronic cardiac valvular disease in four cases; chronic interstitial nephritis in twelve cases, and typhoid fever associated with one case.

In conclusion, I wish to state that, during the year 1907, there were treated in the wards of the Charity Hospital 325 cases of malarial fever, out of which 267 were white and 58 colored, with only two deaths resulting from malarial fever, and those patients were moribund on admission.

125 whites and 26 colored discharged as cured.
134 whites and 28 colored discharged as improved.
7 whites and 3 colored discharged as stationary.
1 white and 1 colored died.

Classified as follows:

| | Colored | . Total. | White, C | olored. | Total. | White. | Improve Colored. | | White. | Stationa Colored. | | White. | Died. Colored. | Total. |
|----------------------|---------|----------|----------|---------|--------|--------|---------------------|-----|--------|----------------------|----|--------|-------------------|--------|
| Malarial cachexia 20 | 8 | 28 | 1 | | 1 | 18 | 7 | 25 | 1 | 1 | 2 | | | |

| Quartan | | 1 | I | | 1 | | | | | | | | | |
| Estivoautumnal 79 | 1.1 | 9 | 39 | 6 | 4.5 | | | | | 1 | 1 | | | |
| Perturbations 2 | 1 | 1 | I | | 1 | 40 | 4 | 4.1 | | | | 1 | | 2 |
| _ | _ | _ | - | | _ | | | | - | _ | - | | | |
| 267 | 58 | 32" | 1-15 | 26 | 1.11 | 134 | 28 | 162 | 7 | 3 | 10 | 1 | 1 | |
| | | | | | | | | | | | | | | |

The two cases reported in this paper were classified as æstivoautumnal, and in my service I had one

case of double tertian, or quotidian, but it was classed as tertian.

THE CORRECT TREATMENT OF FRACTURE OF THE CLAVICLE.

By Rocco Bellantoni, M. D., New York.

Directions for the treatment of fracture of the collar bone are as follows: a, Force the exterior part upward, outward, and backward. b, Push down the interior part. c, Secure the two parts in their correct position until complete union has taken place.

All the efforts of the surgeons are directed toward the avoidance of any deformity of the injured part. The great variety of apparatus and the many methods in use for its treatment demonstrate the practical difficulties in such cases.

The greatest difficulties are not found in the adjustment of the broken ends, but in keeping the parts in good position. I will not mention here the different methods for doing this, because they are too well known, and none of them is perfect.

My method, I assert, is superior to others, for the reason that it is more simple, and yet meets all the requirements of treatment. It is absolutely convenient for the patient, permitting him to walk, to eat, and to sleep without discommoding him to any extent.

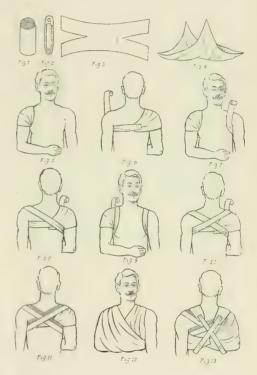

The figures illustrate my method very clearly, and only a few words are necessary to make it entirely comprehensible.

The materials necessary for the operation are: 1, Gauze bandage, three or three and one half inches wide (Fig. 1); 2, about twenty safety pins (Fig. 2); 3, a piece of white linen or cotton fabric, about eight inches wide and one foot and a half long, this fabric must be cut in the middle of each end, as shown in Figure 3; 4, a handkerchief (Fig. 4). large enough for a sling to hold the arm firmly and with safety pins to secure it at the back; 5, a package of absorbent cotton. The dimensions of bandage and cloth that I have here recommended are for an adult of normal dimensions, but it must vary according to the stature of the patient.

The operation begins with fitting well the linen or cotton fabric to the shoulder of the fractured side; the Figures 5 and 6 show clearly the manner how the fabric must be fitted and the ends of it The edge of the bandage must be firmly attached with four pins to the four gathered ends of the cotton fabric (Fig. 6). After this we must exactly bring together the osseous parts. The first turn of bandage is under the armpit of the opposite side (Fig. 6), and then up the same shoulder (Fig. 7); it turns then across the back and under the armpit of the injured side (Fig. 8); then with the remainder of the bandage we repeat the same turns until all is used, making the passes in the form of a figure 8 (Figs. 9, 10, and 11). The binding must be very tight, especially in the first turn, as it must hold the shoulder in the right position and be a firm support for the broken part. These turns made in the form of a figure 8 enable us to secure the two parts in their proper position and the necessary

compression, particularly on the interior side. Finally we fix the unfolded handkerchief (Fig. 4) in the manner indicated in Figs. 12 and 13, viz.: place the elbow bent so that the forearm of the injured side lies across the body in the folded hand-kerchief (Fig. 12), two ends of which are firmly attached to the back, while the other two are brought up to the shoulders and fastened with two strips of bandage crossed on the back (Fig. 13). In the armpits and upon the broken collar bone there must be placed little cushions of absorbent cotton to prevent friction.

The apparatus must be taken off fifteen or twenty days after the operation; and, if the physician thinks it necessary, the dressing may be renewed complete-

ly or reduced to the simple application of the hand-kerchief.

The apparatus is of extreme simplicity: Theoretically it answers to all needs of the case, while practically, if it does not answer well in all cases, it certainly will have advantage over all methods in that it is effective in the complete union of the greatest number of cases. And this without great annoyance to the patient, or great sacrifice of his habits, because the apparatus permits him to sit down, to walk, or to use the other hand for all the ordinary needs of daily life.

371 BROOME STREET.

A NEW OPERATION FOR HÆMORRHOIDS.*

By Charles William Heitzman, M. D., Kansas City, Mo.

All operations for hæmorrhoids may be conveniently classed under three heads: The ligature methods, the Whitehead operation with its modifications, and the clamp and cautery operation. These methods are too well known to require description. The dangers attending these methods, prominently con-

sidered, are:

The ligature method.—The puncture of a needle or a snip of the scissors can readily carry the Bacillus coli communis (whose function as an infective agent in all parts of the body is being recognized more and more) or other pathogenic bacteria into a vein and produce an infective thrombophlebitis with subsequent embolism and death. Given a clean field the same process may be set up, for the thrombi in the hæmorrhoidal veins are frequently already infected presumably with the Bacillus coli communis, and, granted that the thrombi are simply noninfective clots, such an embolus may result seriously.

The Whitehead operation and its modifications .-The common objection to this operation is based on the severity of the hæmorrhage, especially in those more or less debilitated by the loss of blood. The ultimate results of this operation are not always what are to be desired. In a certain number of patients stricture of the anus of greater or less severity develops a most distressing condition. Complete primary union practically never occurs. On the other hand, some of the patients have incontinence of fæces from interference with the nerve supply of the sphincter. In either case the patient has made a poor exchange for his hæmorrhoids. Summed up the objections to this operation are: The danger of simple or infective embolism, the risk of stricture, and the risk of incontinence, which far outweigh its operative nicety.

The clamp and cautery method.—This is the least attractive from a strictly operative standpoint; however, if properly performed, the arguments advanced in its favor greatly outnumber those of the other methods. The danger of infection is reduced to a minimum since there is no wound of the mucous membrane except that produced by the cautery which destroys bacteria and at the same time seals

It will be noticed that the operation which I shall describe bears a similarity to the Mayo procedure for the eradication of varicose veins of the leg.

Description of operation.—After the usual preparation of the patient, the tumors are exposed successively and held between the thumb and the finger or with forceps. An incision is then carried in the long axis of the bowel through the mucous membrane, care being taken so as not to wound the bloodvessels. The bloodvessels being now exposed, they are grasped with forceps and traction applied. This, as a rule, will liberate the vessels, if not, the use of a small, blunt spoon or currette will materially assist in breaking up inflammatory adhesions of the connective tissue. When by this method the hæmorrhoidal vessels are thoroughly exposed through the

cut in the mucous membrane, a ligature of small sized catgut is applied above and below. Now the vessels are extirpated with scissors or knife. incision in the mucous membrane is closed with like suture material. I have found, however, that unless the incision is large it heals just as readily without suturing, being hermetically sealed with blood clot. Should too much redundant tissue remain, it may be removed, carrying the incision in the form of an ellipse and closed as before. It is surprising, however, how much the mucous membrane will shrink after removal of the vessels. The only dressing used is a sterile pad over the anal region. The operation is best performed without the use of sponging, a drip of boric acid solution being employed to keep the

Limitations.—The operation is not applicable to the friable or capillary form, nor to the so called connective tissue or cutaneous hæmorrhoids.

Superiority of the operation.-It is at once thoroughly surgical as well as simple. Little hæmorrhage during the operation and the danger of secondary hæmorrhage are reduced to a minimum. It is a comfortable operation for the patient; there is practically no pain. The edges of the wound are thoroughly coaptated, causing prompt healing and the absence of a cicatrix. The cause is removed, not merely a bunch of mucous membrane, as is often the case with other operations; therefore the probabilities of recurrence are limited, more so than with other operations, to say nothing of unfortunate sequelæ such as I have mentioned.

Treatment of Rocky Mountain Spotted Fever. -According to A. A. Robinson, who publishes an interesting, historical, and clinical study of the disease (Medical Record, November 28, 1908), the treatment of Rocky Mountain spotted fever is principally expectant and symptomatic, no specific medication being available. He notes that some western physicians advise early removal of the tick by applying a volatile oil, such as kerosene or turpentine, and cauterization of the wound with ninety-five per cent. carbolic acid, though this treatment has generally proved futile. Calcium sulphide is regarded favorably and arsenic is said to have a controlling and curative effect on the disease. Kieffer recommends the hypodermic injection of from fifteen to thirty minims twice daily of the following solution:

So lium arsenate, gr. iss; Cocaine hydrochloride, gr. vi; Distilled water, 3iiss.

M. Ft. solutio.

It is thought that atoxyl might be of service in the treatment of spotted fever in view of the results obtained from this preparation of arsenic in trypanosomiasis and in syphilis.

Read before the Tackson County Medical Society, November 3, 1908.

NEW YORK, SATURDAY, DECEMBER 12, 1908.

A RED LETTER YEAR IN PHILADELPHIA CHARITY.

The Thirteenth Annual Report of the Philadelphia Society for Organizing Charity bears this title. The financial crash of 1907 came in October, but it was not until January, 1908, that the applications to the society for relief were double their number in the same month of 1907. In March, April, and May the number of applications was quadrupled. The writer of the report compares the situation to the cry of "Fire" in a crowded public hall. The exits from the danger are described as the exit of emigration, migration, change of occupation, part time work, savings, credit, the help of neighbors, the help of individuals, the help of churches and other social organizations, and the help of relief agencies. He shows how these various methods were employed in Philadelphia from October, 1907, to September, 1908, during which time applications were received at the central office or its branches from 9,946 families and 930 nonresidents, and at the two wayfarers' lodges conducted by the society from 16,254 individuals. In addition to the work secured for applicants, \$36,667.85 were distributed to 5,284 different families.

Much may be done in a given community to relieve the needs of the poor and the unfortunate by referring individual applications to the local society. whose trained investigators will determine the legitimacy of the appeal and provide relief through one of the agencies enumerated above. Physicians in particular are able to assist in lessening the amount of professional indigence in a community by referring demands upon their charity to such a society for investigation. The dispensaries attached to hospitals would do well either to refer applicants for free treatment to such a society or to employ a worker trained along the lines of economics to investigate the claims of those who apply for free

The individual system of relief adopted by societies for organizing charity "makes a loan to one, sends another to the woodyard to work for all he gets, staves off the landlord's eviction notice for a third, finds a chance to work outside for a fourth, places the fifth in a hospital, sends the sixth and his whole family to the country, provides cash for the exceptionally provident buyer who is the seventh, relieves the improvident eighth sparingly with supplies plus a work test, and, instead of doing work twice over, turns the ninth over to the charity that is already caring for him."

The thing most needed during a financial crisis for the self respecting individual is "real work at real wages." That thing is hardest to get. It is much easier for the person with the full pocket to give a piece of money than to help maintain a poor man's self respect by providing the means for him to support himself and his family. The man who does not wish to provide for his own dependents by his own exertions had much better be allowed to go unassisted. The Society for Organizing Charity will attend to the details of investigation for any one who refers cases to it.

THE NATIONAL HEALTH SERVICE.

We commented recently on the prospects of obtaining a national "department" or an enlarged bureau of public health. The arrangement of some of the details may require considerable time. Reference to some of them was made in our previous article.

The plans of those most active in the movement contemplate the transfer of a number of bureaus whose activities are more or less closely related to public health matters to one department and the removal from the latter of other bureaus which have no special relation to health. Thus, it is proposed to transfer part of the work of the Bureau of Chemistry of the Department of Agriculture to another department. We do not see that very much would be gained by this. All the activities of the Bureau of Chemistry are almost inextricably interwoven with purely economic problems, and that portion of the work relating more directly to public health is satisfactorily performed under the present arrangement. work, so far as it relates to public health, is clearly defined. It is the enforcement of the Pure Food and Drug Law, and in this there must of necessity be considered many questions concerning honest labelling, practical methods for the production and preservation of food products, and other subjects which are far more of commercial than of purely hygienic importance. (Witness, for example, the extensive discussions as to the proper labelling of whiskey-a matter of great commercial, but of little public health interest.) We are inclined to think that this work is best done where it is, viz., in a department which is in touch with actual economic conditions. The economic aspects of food problems are, moreover, so important that the Department of Agriculture certainly could not discontinue all work on this subject. A transfer such as is contemplated would almost necessarily mean the establishment of a new Bureau of Chemistry in the Department of Agriculture, and this would result in the duplication of much work. Similar arguments apply to the work of the Bureau of Animal Industry and to that of the Division of Vital Statistics of the Census Bureau; the transfer of parts of this work would mean a similar duplication of machinery.

And we should not lose sight of the fact that as recently as in 1902 Congress, after careful consideration, organized the Marine Hospital Service into the present Public Health and Marine Hospital Ser-This reorganization was effected on such broad lines that Congress evidently expected that the new bureau could, under proper guidance, meet the growing demands for public health work. It would not be strange if Congress should hesitate to reopen this entire subject so soon, especially at a short session. We are not opposed to the general plan of consolidation; it would certainly add dignity to the work, and those who are giving the matter careful consideration do not seem to think that there will be great difficulty in bringing it about. The point we desire to emphasize, however, is that there may be considerable delay in effecting this union, and we fear that some in their enthusiasm have overlooked certain points of more immediate and practical importance.

Granting that such a rearrangement of public health work is secured and a new department or subdepartment established, the strength of the latter will depend solely upon the strength of the units which go to form it. No one questions that by far the most important bureau dealing with public health matters is the present Public Health and Marine Hospital Service, and the strength of the enlarged bureau would at present be determined chiefly by the strength of this service. If this bureau is

transferred to another department, one of the first things necessary to make the enlarged bureau more efficient would be the strengthening of this unit. Why, then, should not those in favor of a stronger national bureau of health use their influence to strengthen the present one? Then, if the proposed consolidation is delayed, something at least will have been gained.

There are at present two measures before Congress which have for their purpose the strengthening of the Public Health and Marine Hospital Service. One of these, known as the Public Health Bill, authorizes the bureau to investigate any disease of interest to the public health, to cooperate with the State boards of health, and to publish and distribute information of a popular nature concerning sanitary matters. It would enable the Hygienic Laboratory to investigate the interstate relations of typhoid fever and other infectious diseases, and the splendid work of Stiles on the hookworm disease in the South (now being carried on under the auspices of the Department of Commerce and Labor and of the President's Farm Commission) would be done in the name of public health. Authority to do work of this character and the means for doing it must be obtained, whether different bureaus are united or not, and the present Public Health Service is admirably organized to do it. Why should we not try to get this legislation carried through at once?

The passage of the second bill now before Congress-the Personnel Bill-is no less necessary and urgent, for not only the strengthening but for the maintaining of the present efficiency of our most important public health agency. Until recently, the pay and other emoluments of the physicians in the three national services have been approximately equal, and the Public Health Service has been able to secure as efficient men for their warfare with disease as the other services have. Recent legislation, urged by the medical profession and by the President of the United States, has properly increased the attractiveness of the other services greatly, so that now the pay of men of equal ability, age, and experience in the other services is far in excess of that of those in the Public Health Service. Unless this condition is remedied in the very near future, it is self evident that the efficiency of the service will diminish and the efficiency of the proposed new bureau will be correspondingly less. The Personnel Bill (which has passed the Senate and is now before the House) simply provides that the pay and other emoluments of the members of the Public Health and Marine Hospital Service shall be approximately equivalent to those in the other branches. Those who are most enthusiastic over the proposed national health movement seem to us

to be losing a golden opportunity of doing something of immediate and practical usefulness. "Unpreparedness for war" has been a potent argument in the legislation for increasing the efficiency of the medical corps of the army and navy. Have we not reached the stage of civilization where preparation for the incomparably greater warfare against preventable disease should be equally potent? This is a matter of such vital importance that physicians should use all their influence by appealing to their Congressmen and Senators to urge the immediate passage of these two bills. Even if the bureaus are united, this work will have to be done if the larger bureau is to have anything more than a nominal existence. Why not take advantage of what has already been accomplished and turn our hands to what lies nearest to us?

THE SERUM TREATMENT OF HÆMOPHILIA.

Here in New York there has of late been some indication of a tendency to revive transfusion of blood for the purpose of arresting hæmorrhage in hæmophiliacs. It seems, however, that a less formidable procedure is sufficient—that of injecting a small amount of normal serum into a vein or even under the skin. In cases of an accessible wound, too, a simple dressing of serum has been known to prove efficacious. The investigations that have led up to the establishment of the serum treatment have been largely the work of our French brethren, and particularly that of Dr. Emile Weil.

Summarizing the observations of Weil and others, Dr. François Dejardin, of Liège, Belgium, contributes an interesting article to the July number of the Archives provinciales de chirurgie. He outlines the leading points in our knowledge of the nature of hæmophilia, covering both the hereditary and the acquired forms, and of the modes of action and degrees of efficacy of such remedial measures as the administration of calcium chloride, the injection of gelatin, and the topical use of styptics, including that of adrenalin. The use of normal serum is shown to be preferable to that of any other agent, though Dejardin properly advises that the concomitant employment of other measures should not be neglected.

We may use the fresh serum of the rabbit, the horse, or the human subject. If it is employed by intravenous injection, the amount injected daily should be from ten to twenty cubic centimetres (approximately, from two and å half to five fluid drachms); if it is injected subcutaneously, the amount should be from ten to thirty cubic centimetres (from two and a half to seven and a half

fluid drachms). It is sufficient to continue the injections for two or three days, during which time the desired effect will have been secured, whether the checking of an existing hæmorrhage or the prevention of undue bleeding in the course of a contemplated operation; and the benefit may be expected to last for a month or more.

For some unexplained reason, it is dangerous to use the serum of the ox, as has been shown in a number of cases. If an emergency arises under circumstances in which the fresh serum of the rabbit, the horse, or the human subject is unavailable, a perfectly efficient substitute is to be found in the ordinary antidiphtheritic serum. This fact seems to have been announced first by Weil, but in actual practice Dejardin had anticipated Weil's publication of it. The antidiphtheritic serum, of course, is now readily obtainable almost everywhere; consequently the serum treatment of hæmophilia can always be carried out by the general practitioner. There is reason to believe that it will prove of general benefit in this curious disease.

THE DISINGENUOUS ANTI-VIVISECTIONIST.

Dr. Walker B. Cannon, of Boston, the chairman of the American Medical Association's Council on Defense of Medical Research, has issued a circular, dated December 1st and addressed to editors of medical journals, in which he asks for the aid of the journals in "obviating as completely as possible any cause for complaint against animal experimentation." He goes on to remark that much of the "evidence" cited by hostile agitators is taken from articles in medical journals, said agitators seeking to make it appear that the investigations on animals referred to in the articles were conducted without the use of an anæsthetic. Dr. Cannon therefore says: "In every instance in which anæsthesia is a condition of the investigation, will you not point out to authors the importance of making that fact prominent?"

While we do not see the necessity of giving prominence to the statement that anæsthesia was secured in experiments that would have been painful without it, we do appreciate the desirability of noting the fact, and we shall be glad to take the course suggested by Dr. Cannon so far as a plain statement is concerned, and that ought to be sufficient for the purpose. It goes without saying, of course, that an author's omission of such a statement is due to his taking it for granted that the reader of his article does not need to be told in every instance that an experiment was conducted with the animal in a state

of anæsthesia. Medicine is a humane profession, and it is distinctly disingenuous for the opponents of vivisection to convey the impression that anæsthesia was omitted in a given instance simply because the experimenter has not thought it necessary to proclaim the fact that it was employed. But we must head off this disingenuousness, and we therefore request our contributors to accede to Dr. Cannon's suggestion.

THE ARMY TO BE IMMUNIZED AGAINST TYPHOID FEVER.

By the courtesy of Surgeon General O'Reilly, who presided at the sessions of the board of officers of the Medical Reserve Corps, which was convened at the War Department on December 7th, to consider the advisability of immunizing the army against typhoid fever, both in time of peace and during war, we are enabled to present the findings and recommendations of the board, which consisted of the following members: Surgeon General Robert M. O'Reilly and Captain Frederick F. Russell, of the Medical Corps, recorder, and First Lieutenant Victor C. Vaughan, First Lieutenant John H. Musser, First Lieutenant William T. Councilman, First Lieutenant Alexander Lambert, First Lieutenant Simon Flexner, and First Lieutenant William S. Thaver, of the Medical Reserve Corps.

The board found that the practice had been used during the Boer war in South Africa, where about one hundred thousand men were vaccinated, but that no reliable statistics were at hand to show the results since that time. However, about fifteen thousand men in the English and German colonial armies had been vaccinated against typhoid, and complete and carefully compiled statistics had been collected, from a consideration of which the board was convinced that the vaccination was quite harmless and that it would be of great service in diminishing the amount of typhoid fever among troops, especially in time of war. It therefore recommended that the practice of vaccination be introduced into the regular and volunteer armies in time of war.

The board further recommended that in times of peace all the men be given an opportunity to be protected against the disease, and that special efforts be made to vaccinate as many of the Hospital Corps and Nurse Corps and any others especially exposed as possible. It recognized that this disease spread by contact from man to man, and to an even greater extent than in the civil population; that in the Spanish war it produced an enormous amount of sickness and was the cause of eighty-five per cent. of all deaths; and that vaccination was a practicable, harmless, and effective that it is the contract of the camp epi-

demics which we had at that time. The board, therefore, recommended, with admirable foresight, the immediate introduction of the practice into the army so that the disease might be reduced to a minimum, and the necessary machinery for vaccinating large bodies of troops in time of war might be already on hand and available for use, and that the Medical Corps might become familiar with the technique of vaccination.

THE OUTCOME OF A NEWSPAPER SLANDER.

Many of our readers will recall the fact that, more than six months ago, a Philadelphia newspaper grossly misrepresented certain remarks made in a medical meeting by a distinguished physician and philanthropist, Dr. S. Adolphus Knopf. It will be remembered that the newspaper in question represented Dr. Knopf as having spoken in favor of "euthanasia" in the newspaper sense of the term, a sense which, though utterly false, has been hopelessly hammered into the popular mind, a sense which convicts those who approve of true euthanasia—as we all approve of it—of being potential murderers. The Philadelphia paper's slander was copied far and wide, and Dr. Knopf was vilified correspondingly. We protested against the slander at the time (see the New York Medical Journal for May 18th), and we are now glad to be able to record the fact that a suit brought by Dr. Knopf against the paper has been settled out of court, the paper paying Dr. Knopf a handsome sum in damages and publishing a correction of its original libellous statement. The amount of money received by Dr. Knopf from the newspaper has nobly been turned over by him to the funds of the National Association for the Study and Prevention of Tuber-Truly may it be said, therefore, that he has suffered for the cause of enlightenment regarding tuberculous disease, a cause for which he has labored unselfishly and unceasingly for many years.

Rems Atems.

Mrs. Sage's Gift to Nassau Hospital.—Mrs. Russell Sage has given \$5,000 to endow a bed in the hospital in memory of her friend, Miss Kate Riddell.

The Cottage State Hospital at Blossburg, Pa., will obtain the services of Dr. Frederick G. Davis, of Blossburg, as a member of the Board of Trustees, by the appointment by the Governor of Pennsylvania.

The Harvey Lectures.—The sixth lecture in the Harvey Society course will be delivered on Saturday, December 19th, at 8:30 p. m., at the New York Academy of Medicine, by Professor A B. Macallum, of the University of Loronto. The subject will be Osmosis

New Officers of the Philadelphia Society of Physiology. At a recent meeting of the Society of Normal and Pathological Physiology of the University of Pennsylvania, the following officers were elected for the ensuing year: President, Dr. David H. Bergey; vice-president, Dr. J. G. Hickey; secretary and treasurer, Dr. Harold B. Wood.

Changes of Address.—Dr. Flora M. Phelps, from Ocean Grove, N. J., to 224 West Fifty-second Street, New York.

Dr. Lindsley F. Cocheu, to The Colonial Studios, 39
West Sixty-seventh Street, New York.
Dr. Benjamin P. Farrell, to 256 West Fifty-seventh
Street, New York.

The Clinical Society of the Elizabeth, N. J., General Hospital will hold its next meeting on Tuesday, December 15th, at 9 p. m. Dr. E. B. Grier will read the paper of the evening on Some Inflammatory Conditions of the Falloppian Tubes.

The Mütter Lecture.—The annual Mütter lecture of the Philadelphia College of Physicians was delivered on Friday evening, December 11th, by Dr. George W. Crile, professor of clinical surgery at the Western Reserve University, Cleveland, Ohio. The subject was Surgical Anæmia

Resuscitations

The Pathological Society of Philadelphia.—At the regular semimonthly meeting of the Pathological Society of Philadelphia, held on Thursday, December 10th, Dr. F. Creighton Wellman, of Angola, Portuguese West Africa, spoke on the Relation of Insects to the Transmission of Disease

The Syracuse, N. Y., Academy of Medicine. - The regular meeting of this academy was held on Tuesday evening, December 8th. Dr. Nathan Jacobson read a paper on Senile Changes in the Prostate Gland, and Dr. Henry L. Elsner read a paper on Senile Pneumonia. Officers to serve for the year 1909 were nominated.

The West End Medical Society of New York.—The annual meeting of this society will be held on Saturday, December 19th, at the home of Dr. Charles Gilmore Kerley, 732 West Eighty-first Street, New York. Dr. W. Gilman Thompson will read a paper on Hospital Problems of Greater New York, and officers for the ensuing year will be

The Richmond, Va., Academy of Medicine.—The annual meeting of the academy was held on Tuesday, December 8th. Dr. E. Guy Hopkins read a paper entitled Some Internal Diseases due to Animal Parasites. Dr. W. A. Shepherd read a paper on Blood Changes in Leuchæmia and Pernicious Anæmia. Officers for the ensuing year

were elected.

Open Air School for Tuberculous Children .- A school for tuberculous children will be opened next week on the deck of the ferryboat, which is moored in the East River near Bellevue Hospital and is used as a day camp for tuberculosis patients. There will be accommodations for fifty pupils. Mr. Jacob J. Shufro has been appointed teacher by the Board of Education.

Contagious Diseases in Chicago.—During the week

ending November 28, 1908, there were reported to the Department of Health of the City of Chicago 968 cases of contagious diseases, as follows: Diphtheria, 222 cases; scarlet fever, 255 cases; chickenpox, 90 cases; pneumonia, 31 cases; tuberculosis, 189 cases; typhoid fever, 44 cases; whooping cough, 13 cases; diseases of minor importance,

25 cases.
St. Luke's Hospital, New York, to be Enlarged. Plans and specifications are being prepared for a ten story building to be erected in connection with St. Luke's Hospital, Morningside Avenue and One Hundred and Thirteenth Street, New York. The façades will be of marble and granite, light pressed brick and ornamental terra cotta, and the style will be in keeping with the present buildings of the hospital.

The Northwestern Medical Society of Philadelphia

held a stated meeting on Monday evening, December 7th. The programme consisted of a symposium on peritonitis. Papers dealing with the subject from the standpoint of the pædiatrician, from the standpoint of the surgeon, from the medical standpoint, and from the standpoint of the surgeon, from the medical standpoint, and from the standpoint of the gyne-cologist were read by Dr. James H. McKee, Dr. W. Wayne Babcock, Dr. Samuel Wolf, and Dr. Wilmer Krusen.

The Tri-State Medical Association of Arkansas, Mississippi, and Tennessee, held its twenty-fifth annual meeting in Marchia process.

ing in Memphis recently, and elected the following officers to serve for the ensuing year: President, Dr. William H. Deaderick, of Marianna, Ark.; vice-president for Arkansas, Dr. T. S. Hare, of Vincent; vice-president for Mississippi, Dr. S. W. Glass of Dublin; vice-president for Tennessee, Dr. J. A. Porter, of Ripley; secretary, Dr. Eugene Rosamond, of Memphis; treasurer, Dr. J. A. Vaughan, of Memphis.

American Pharmaceutical Association.—The City of Washington Branch of this association will hold a stated

Washington Branch of this association will hold a stated meeting on Monday evening, December 14th, in the National College of Pharmacy. The programme will include the following: Inaugural Address, by Dr. Harvey W. Wiley; The Analysis of Headache Mixtures, by Dr. W. O. Emery; The Assaying of Drugs, by Dr. C. E. Parker; Adulterated Drugs, by Dr. Lyman F. Kebler.

The Buffalo Academy of Medicine—The regular meeting of the Section in Medicine was held on Tuesday evening, December 8th. Dr. James W. Putnam read a paper entitled A Study of the Effects of Tedious Labors and Forceps Deliveries in the Production of Epilepsy Spasmic Paralysis, and Idiocy. Dr. P. W. Van Peyma discussed the subject from the obstetrical standpoint, and Dr. Irving M. Snow from the standpoint of pædiatrics. Charitable Bequests.—By the will of Peretz Rabino-

Charitable Bequests.—By the will of Peretz Rabinowitz the Hebrew Orphans' Home, Philadelphia, receives

By the will of Samuel Wakeling, the Home for Incurables, Philadelphia, and the Children's Hospital, Philadelphia, become contingent legatees.

At the third quarterly meeting of the Federation of Jewish Charities, Philadelphia, \$344,075 were distributed among the various Jewish charitable and beneficiary societies in

Philadelphia.

The Rochester, N. Y., Academy of Medicine.—The regular monthly meeting of the Section in Surgery, which includes anatomy, orthopædic surgery, ophthalmology, otology, laryngology, dermatology, and genitourinary surgery, was held on Wednesday evening, December oth. The programme included two papers, one entitled Deviations and Spurs of the Nasal Sæptum and their Removal by Submucous Resection, by Dr. Nathan D. MacDowell, and the other on Operative Lateral Sinus Thrombosis, by Dr. Bradford A. Richards.

The Philadelphia County Medical Society.—The Central Branch of this society held a meeting on Wednesday evening, December 9th. The programme included the folevening, December 9th. The programme included the following papers: Dysmenorrhæa and Allied Manifestations, by Dr. Ella B. Everitt; A Short Account of the International Congress on Rhinology and Laryngology, held in Vienna in 1908, by Dr. Margaret F. Butler; Suggestions Concerning the Treatment of Fractures, by Dr. Harriet L. Hartley; A Brief Statement of Our Knowledge of Cancer, by Dr. Martha Tracy.

The Health of Pittsburgh .- During the week ending November 28, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 13 cases, 0 deaths; typhoid fever, 17 cases, 3 deaths; scarlet fever, 39 cases, 4 deaths; diphtheria, 28 cases, 5 deaths; measles, 16 cases, 1 death; whooping cough, 5 cases, I death; pulmonary tuberculosis, 36 cases, 9 deaths. The total deaths for the week numbered 166 in an estimated population of 565,000, corresponding to an annual death rate of 15.27 in 1,000 population.

A Dinner to Dr. F. Creighton Wellman .- Dr. Thomas A Dinner to Dr. F. Creighton Wellman.—Dr. Thomas H. Fenton, ex-president of the American Society of Tropical Medicine, gave a dinner on Thursday evening. December 3d, at the Art Club, in honor of Dr. F. Creighton Wellman, who has been in Angola, West Africa, for the past eight years, in the employ of the Portuguese Government Among the guests were Dr. James M. Anders, Dr. Edward J. Nolan, Dr. Joseph McFarland, Dr. John M. Swan, Dr. Henry Skinner, Dr. Roland G. Curtin, Dr. Alfred C. Lambdin, and Dr. James C. Wilson.

Personal Dr. Wilfred T. Granfall the English spec

Personal.-Dr. Wilfred T. Grenfell, the English speresonal.—Dr. Wilfred I. Grenfell, the English spe-cialist and philanthropist, will visit Baltimore on December 15th and 16th. While he will be the general guest of the Grenfell Society of Baltimore, he will be the special guest of Dr. Henry M. Hurd, of the Johns Hopkins Hospital. Dr. Carlos Finley has been appointed honorary chief of the National Department of Sanitation of Cuba, in recog-pition of his discovery of the posquity theory of vallow

nition of his discovery of the mosquito theory of yellow

Dr. F. D. Andrew, of Rochester, N. Y., has had his left hand amputated, as a result of disease caused by exposure

Miss Ida Uraka, who graduated with honors from the University of Berlin, was recently appointed a professor in the medical college of Tokio, Japan. Miss Uraka is the first woman to hold such a position in Japan, and she is meeting with much opposition from the conservative ele-

The New Maternity Hospital at Springfield, Mass .--The Wesson Materinty Hospital, a beautifully equipped, modern institution, was dedicated with proper exercises on November 20th. Mr. William W. McClench, president of November 20th. Mr. William W. McClench, president of the board of trustees, presided, and the building was formally turned over to the trustees by Dr. P. W. Roberts, who made the principal address. The funds for the building of this institution were given by the late Mr. Daniel B. Wesson, who also provided for its maintenance by an endowment fund of \$25,000.

Popular Science Lectures in Philadelphia.—Announcement has been received of the Ludwick Institute Courses of Free Lectures on the Natural Sciences and their Application, which gas held under the assigner of the Acade-

Application, which are held under the auspices of the Acad-Approximation, which are need under the auspices of the Academy of Natural Sciences of Philadelphia. There are eight courses in the series, with five lectures in each course. These lectures are free to the public, and complete programmes of the courses may be obtained from the chairman of the Ludwick Institute Committee on Instruction.

Dr. Samuel G. Dixon, or from the academy.

A Tuberculosis Exhibition at Tuskegee.—A negro

congress on tuberculosis will be held at Tuskegee, Ala, during the week of December 14th. The National Association for the Study and Prevention of Tuberculosis will send its traveling exhibit, where it will be displayed on the grounds of the institute. An extensive programme of illusgrounds of the institute. An extensive programme of instructed addresses, platform meetings, and conferences has been arranged, along the lines of the recent International Tuberculosis Congress at Washington. This is the first congress ever devoted wholly to the welfare of the negro

Dr. Edward N. Brush Honored.—A public dinner was tendered Dr. Edward N. Brush, of the Sheppard and Enoch Pratt Hospital, Baltimore, on Friday evening, December 11th, by his many friends, who wished to express their per-Itth, by his many friends, who wished to express their personal regard for him and their appreciation of the great service he has rendered in the public and private care of the insane. Dr. Brush has completed thirty years of service in the institutions of New York, Pennsylvania, and Maryland; was at one time editor of the American Journal of Insanity; and has contributed largely to the literature

of psychiatry. Deutscher medizinische Gesellschaft der Stadt New Monday evening, December 7th, in the New York Academy of Medicine, Dr. S. Adolphus Knopi delivered an address on the Modern Fight against Tuberculosis Considered from the Social Medical Point of View. Among those who took part in the general discussion which followed were Mrs. Fiedler, a delegate of the French Government to the Tuber-culosis Congress; Dr. H. M. Biggs, Dr. J. Winters Bran-nan, Professor Livingston Farrand, Dr. A. Caillé, Dr. A. Jacobi, Dr. A. Meyer and Dr. Franz Torek.

Medical School Inspection in Chicago.—During the week ending November 28, 1908, the school medical inspectors examined 4,475 pupils, and excluded 271 on account of contagious diseases. Physical examinations were made of 434 pupils, of which 193 were advised to seek medical attention. The school nurses made 5,227 calls during the week, seeing 2,782 pupils. Of these 405 were referred to the school medical inspectors, 203 were sent to dispensaries, 18 were sent to hospitals, 249 to family physicians, 30 to the Visiting Nurses' Association, 3 to the Bureau of Charities, 5 to the Relief and Aid Society, and 10 to the County Agent.

The Colorado Souvenir Book for the International Congress on Tuberculosis, issued by the Colorado State Organization of the International Congress on Tuberculosis organization of the international Congress on Functionals contains much interesting information. It consists of 192 pages, is well printed, and beautifully illustrated. The first twenty-seven pages are devoted to articles by prominent Colorado physicians on the influence of the climate of Colorado on pulmonary tuberculosis, asthma, hay fever, nontuberculous pulmonary disorders, cardiac affections, and nervous diseases. A valuable feature of the book is a chapter on the Climates of the United States, by Dr. Charles charts of the United States, with a statement by General W. B. Hazen, chief signal officer at the time the statistics were compiled, to the effect that the seasonal averages do not vary five per cent, at the most in any instance from the general averages obtained for like periods since observations were commenced by the Signal Service. The book contains much general information regarding the State of

industries, resources, railways, mines, and forests. The beauties of Colorado's natural scenery are fully described and illustrated, as are also the principal towns and cities of the State. A list of the sanatoria in the State completes the volume. The book is distributed free to members of the International Congress and of the Colorado State Organization. Others who are interested may obtain copies by applying to the Exhibition Committee of the Colorado State Organization, 823 Fourteenth Street, Denver. price is 25 cents a copy.

Infectious Disease in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statistics of new cases and deaths reported for the two weeks ending De-

| | Nov. 28 | |

Wills Hospital, Philadelphia, Ophthalmic Society. This society held a clinical conference on Monday after-noon, December 7th. Dr. Samuel D. Risley presented clin-ical memoranda showing a cause for some cases of persist-ent asthenopia. He also presented interesting data relating to intraocular harmorrhage. Dr. Charles A. Öliver reported a case of hypertrophy of the bulbar conjunctiva in an adult, a case of hyperrophy of the bilina confidence in an additional and presented a patient showing extensive blepharoplasty for restoration of the left upper lid. Dr. William Campbell Posey demonstrated Meller's operation for removal of the Poscy demonstrated Mener's operation for removal of the lachrymal sac. Dr. William Zentmayer made some remarks on retinochoroiditis juxta papille, and exhibited a patient. Dr. Harold Goldberg read a paper entitled The Report of

the Pathologist.

Vital Statistics of New York -During the week ending November 28, 1908, there were reported to the Department of Health of the City of New York 1,290 deaths from ment of Health of the City of New York 1.200 deaths from all causes, as compared with 1.346 for the corresponding period in 1007. The annual death rate in 1,000 population was 15.22 m the whole city, and in each of the boroughs it was as follows: Manhattan, 13.09; the Bronx, 20.39; Brooklyn, 15.62; Queens, 15.25; Richmond, 21.77. Of the total number of deaths 3,46 were of children under its years of age, and of these 222 were of children under one year of age. There were 82 violent deaths, 5 of which were due to homicide, 16 to suicide, and 61 to accidents. There were 140 stillbirths. Nine hundred and ten marriages and 2,357 births were reported during the week.

The Mortality of Chicago.—There were reported to the Department of Health of the City of Chicago 520 deaths from all causes during the week ending November 28, 1908. The annual death rate in 1,000 population was 12.52. Of the total number of deaths 161 were of children under five years of age, of which 112 were under one year of age. The principal causes of death were: Apoplexy, 12 deaths; Bright's disease, 20 deaths; bronchitis, 11 deaths; consumption, 62 deaths; cancer, 25 deaths; diphtheria, 9 deaths; heart diseases, 49 deaths; intestinal diseases, acute, deaths; meart unseases, 49 deaths; mestmar unseases, acute, 42 deaths; measles, 4 deaths; nervous diseases. 18 deaths; pneumonia, 61 deaths; scorlet fever, 13 deaths; suicide, 3 deaths; typhoid fever, 8 deaths; violence, other than suicide, 31 deaths; whooping cough, 1 death; all other causes, 142 deaths.

Scientific Society Meetings in Philadelphia for the Week Ending December 19, 1908:

MONDAY, December 14th.—Society of Normal and Patho-

logical Physiology.

Tussday, December 15th.—Dermatological Society; Academy of Natural Sciences; North Branch, Philadelphia County Medical Society.

Wrest toy, December 16th Section in Otology and Laryngology, College of Physicians; Franklin Insti-

tute.

Thursday, December 17th.—Section in Ophthalmology,
College of Physicians; Section Meeting, Franklin Institute; Southwark Medical Society; Northeast Branch,
Philadelphia County Medical Society; Delaware Valley
Ornithologists Club, Academy of Natural Sciences.

France December 18th American Philosophical Society.

The Section in Genitourinary Diseases of the New York Academy of Medicine will hold a stated meeting on Thursday evening, December 17th, at 3.3 clock Dr. B. Merrill Ricketts, of Cincinnati, will be the guest of the evening, and will read a paper on the Surgical Anatomy and Pathology of Ureteral Calculus and Its Operative Indications. It will be illustrated with lantern slide pictures. Other papers on the subject of the surgery of ureteral calculi will be read as follows: The Treatment of Ureteral Calculus, by Dr. A. V. Moschcowitz; The Operative Technique of Calculi Impacted in the Lower End of the Ureter, by Dr. C. L. Gibson; Cystoscopic Aid in the Diagnosis and Treatment of Ureteral Calculus, by Dr. A. T. Osgood; X Ray Aid in Diagnosis of Ureteral Calculus, with lantern slide demonstration, by Dr. L. Taches. The subject will be discussed by Dr. F. Tilden Brown, Dr. Willy Meyer; Dr. John F. Erdmann, Dr. Howard Lilienthal, Dr. Eugene W. Caldwell, and Dr. Lewis Gregory Cole. dications. It will be illustrated with lantern slide pictures

Free Medical Lectures at Harvard.-The faculty of the Harvard Medical School have announced the customary course of popular lectures on medical subjects. There are thirty-two lectures in the course, which will be given on Saturdays at 8 p. m., and Sundays at 4 p. m., dusing the first four months of the new year. The following is a list first four months of the new year. The following is a list of the subjects of the lectures for the month of January January 3d, Fifty Years of Surgery, by Dr. David W. Cheever; January 9th, Some Things Parents Should Know about the Teeth of their Children, by Dr. Charles A. Brackett; January 10th, Anatomical Variations, by Dr. Thomas Dwight; January 10th, Anatomical Variations, by Dr. Thomas Dwight; January 10th, Auditory Vertigo, Deafness due to Ear Diseases, by Dr. Clarence J. Blake; January 17th, Inflammation, by Dr. William T. Councilman; January 23d, Diphtheria and Scarlet Fever, by Dr. John H. McCollom; January 24th, The Circulation of the Blood, by Dr. William T. Perter; January 3oth, On the Work for the Relief of the Sick of Various Agencies other than Medical, by Dr. January 13tk Rabies (illustrated). by Dr. James J. Putnam; January 31st. Rabies (illustrated), by Dr. Langdon Frothingham.

The Health of Philadelphia.- During the week ending November 28, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 22 cases, 6 deaths; scarlet fever, 69 cases, 2 deaths; chickenpox, 91 cases, 0 deaths; diphtheria, 111 cases, 16 deaths; cerebrospinal meningitis, 1 case, I death; measles, 40 cases o deaths; whooping cough, 6 cases, I death; tuberculosis of the lungs, 102 cases, 49 6 cases, 1 death; tuberculosis of the lungs, 102 cases, 49 deaths; pneumonia, 45 cases, 42 deaths; erysipelas, 8 cases, 0 deaths; puerperal fever, 5 cases, 0 deaths; mumps, 9 cases, 0 deaths; cancer, 16 cases, 29 deaths; trachoma, 2 cases, 0 deaths; tetanus, 1 case, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than that of the lungs, 2 deaths; the control of the lungs, 2 deaths; d diarrhœa and enteritis under two years of age, 8 deaths; dysentery, 2 deaths. The total deaths numbered 435 in an estimated population of 1,532,738, corresponding to an annual death rate of 14.71 in 1,000 population. The total infant mortality was 86; under one year of age, 72; between one and two years of age, 14. There were 27 stillbirths; 17 males and 10 females. There was only a trace of pre-

cipitation.

The Medical Society of the County of Ulster, N. Y. The annual meeting of this society, which was established in 1806, was held in Kingston, N. Y., on Tuesday, December 1st. Dr. Aden C. Gates, of Kingston, the retiring president, delivered the annual presidential address. Professor francis Valk, of the New York Postgraduate Medical School and Hospital, read a paper entitled The Eye Yesterday and To-day. Dr. J. J. Thomson, of the Manhattan Eye and Ear Hospital. New York, read a paper on Mastoiditis. Officers for the ensuing year were elected as foliows: Dr. James L. Preston, of Kingston, president; Dr. Thomas Keator, of Accord, reelected vice-president; Dr. Thomas Keator, of Kingston, reelected secretary; Dr. E. E. Norwood, of Kingston, treasurer; censors. Dr. Adelbert Mambert, of Kingston; Dr. Mark O'Meara, of Kingston; Dr. Aden C. Gates, of Kingston; Dr. Daniel Connelly, of Kingston; and Dr. Albert H. Palmer, of Marlborough; delegate to the Medical Society of the State of New York, Dr. Elbert H. Loughran, of Kingston; alternate, Dr. A. A. Stern, of Kingston; delegate to the Third District Branch Medical Society, Dr. Frank Keator, of Kingston; alternate, Dr. Joseph Bongartz. The following physicians were received into membership in the society: Dr. E. Forest Sibley, of Kingston; Dr. John R. Gillett, of Kingston; and Dr. Frederick Snyder, of Rosendale. Francis Valk, of the New York Postgraduate Medical

A Renewed Effort to Prevent Vivisection .- The medical profession of the State of New York has been requested to oppose the passage of a bill which is about to be introduced into the legislature to restrict experiments on living animals. The following circular letter has been sent to the physicians of the State by the Medical Society of the State of New York:

State of New York:

The be Practitioners of Medicine of the State of New York

The Society for the Prevention of Abuse in Animal Experimentation last year caused to be introduced into the Legislature of this State a bill seriously restricting experiments on living animals. The above named society now enters the field again and proposes another bill of the same general character as that of last year. The Medicial Society of the State, through its committees on legislation and experimental medicine, successfully opposed the passage of last year's measure. Acting under the resolution referring to animal experimentation, which was passed at the last animal medicine will oppose the passage of the proposed bill. We therefore urge all members of the medical profession to disapprove the measure and on its introduction into the Legislature, to work in all legitimate ways for its defeat. Specific objections to it will be presented later.

(Signed) Chairman of the Committee on Legislation.

Chairman of the Committee on Legislation.

JOSEPH D. BRYNNI.

Chairman of the Committee on Experimental Medicine. Secretary of the Committee on Experimental Medicine.

The Health of the Canal Zone.-During the month of September, 1908, there were reported 259 deaths in the Canal Zone, in a population of 124,734, corresponding to an annual death rate of 24.91 in a thousand population. Among the employees of the Canal Commission and the Panama Railroad there were 48 deaths, in a total force of 45,058, corresponding to an annual death rate of 12.78 in a thousand. ing to an annual death fate of 12.76 in a thousand. There were 3 deaths from typhoid fever, 32 from malarial fever, 13 from asstivoautumnal fever, 1 from hamoglobinuric fever, 2 from diphtheria, I from amobic dysentery, 10 from clinical dysentery, 2 from beriberi, 1 from purulent infection and septichæmia, I from rabies, 24 from tuberculosis of the lungs, 2 from other forms of tuberculosis, I from of the lungs, 2 from other forms of tuberculosis, 1 from syphilis, 2 from cancer, 1 from acute articular rheumatism, 1 from alcoholism, 3 from tetanus, 6 from bronchopneumonia, 16 from pneumonia, 17 from diarrhea and enteritis, under two years of age, 1 from uncinarisis, 2 from puerperal septichæmia, and 1 from gangrene. The morbidity report shows that there were an average of 600.90 white employees constantly sick in hospitals, sick camps, and in quarters, or a morbidity rate of 48.58 in a thousand; 529.82 colored employees were sick daily, or a morbidity rate of 16.21 in a thousand; and 1,130.81 employees of all colors sick daily, a morbidity rate of 25.00 in a thousand colors sick daily, a morbidity rate of 25.09 in a thousand

Society Meetings for the Coming Week:

Monday, December 14th.—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association

tion; Waterbury, Conn., Medical Association.

TUESDAY, December 15th.—New York Academy of Medicine (Section in Medicine); Buffalo Academy of Medicine (Section in Pathology); Tri-Professional Medical Society of New York; Medical Society of the County of Kings, N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association.

Wednesday, December 16th.—New York Academy of Med-icine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York (annual); New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club; New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

FHURSDAY, December 17th.—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Æsculapian Club of

Buffalo, N.

FRIDAY, December 18th.—New York Academy of Medicine (Section in Orthopædic Surgery); Clinical Society of the New York Postgraduate Medical School, and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

Bursitis Subacromialis, or Periarthritis of the Shoulder
Joint. (Subdeltoid Bursitis), (Concluded),
By Ernest Amory Codman.

The Method of Administering Antimeningitis Serum.-Dunn reports fifty-seven cases of meningitis, in which the patients were treated with antimeningitis serum. He says: Perform lumbar puncture, prepared to give the serum as soon as meningitis is suspected. If the fluid is cloudy, give the first full dose of serum at once, without waiting for the bacterial examination, although further doses are only to be given in case the Diplococcus intracellularis is found in the cerebrospinal fluid. The serum is of no value in other forms of meningitis. At every dose give as much as possible. Always withdraw as much cerebrospinal fluid as possible. Give 30 c.c. in all cases in which the amount of fluid withdrawn is 30 c.c. or less, unless a distinctly abnormal sense of resistance is encountered after as much has been injected as has been withdrawn. In all cases in which the amount of fluid withdrawn is more than 30 c.c., give as much serum as the quantity withdrawn. In very severe or fulminating cases, in which the amount withdrawn is between 30 c.c. and 45 c.c., give 45 c.c. unless abnormal resistance is encountered. In very severe or fulminating cases repeat within twenty-four hours as soon as the patient begins to get worse again, or at twelve hour intervals. In average cases repeat daily, until four full doses have been given in all cases. If diplococci persist after four full doses have been given, continue the injections until they have disappeared. If subjective symptoms, any impairment of the mental condition, or fever persist after diplococci have disappeared, or after four full doses have been given without progressive improvement, wait four days if the condition of the patient is stationary. At the end of four days, or at any time if the patient's condition is getting worse, repeat the treatment with four daily full doses, and continue as if this were the original attack. When a relapse occurs, either by reappearance of diplococci in the cerebrospinal fluid or by a reappearance of symptoms, give four daily full doses and continue treatment as if this were the original attack. Treatment along these lines should be continued until the patient is symptom free, without diplococci in the fluid, or until the chronic stage is established. In the chronic stage, watch for possible reappearance of diplococci by doing occasional lumbar punctures. If diplococci reappear, resume treatment with the serum as outlined above. In chronic cases with excessive cerebrospinal fluid under mari ed pressure, try dail: hunbar puncture without the injection of serum.

3. Hyperpyrexia in Children. - Marvel observes that pyrexia is a complex phenomenon occurring as a result of infection, injury, nervous shock, or disturbance, the causal relations of which are as yet far from being wholly understood. Hyperpyrexia is merely an aggravated pyrexia, and when present in certain diseases, such as bronchopneumonia, meningeal and pulmonary tuberculosis, pneumonitis, or severe injuries to the nervous system is of grave significance. The rational use of cold water, properly sustained by artificial and internally stimulating agents, even in the extremely high temperatures, may, not infrequently, be followed by success. Hyperpyrexia in children, though always signifying grave danger, is not so likely to be accompanied by fatal results, as in

5. Clinical Value of Spirochæta Pallida.-Harris and Corbus say that the following facts represent the principal reasons for considering the Spirochata pallida specific. It has been found innumerable times by observers in all parts of the world, and has only been found in syphilitic, never in nonsyphilitic lesions. It has been found in the lesions of every stage of syphilis, even in the gummatous or so called tertiary stage, and in every type of syphilitic lesion. Syphilitic material containing spirochætæ has been inoculated into monkeys and the spirochætæ demonstrated in the lesions so produced. Material from these lesions produced the disease in a second series of monkeys and so on for forty-two successive inoculations, all the lesions of which showed the spirochætæ. Human material containing the spirochætæ gives the reaction for antigen with the serum of syphilities. But the great difficulty is the staining methods. By the best method the organisms stain so faintly that it usually requires a prolonged search to find them. Again, it is very difficult to distinguish the stained specimen from

other spirochætælike organisms. Hoffmann, Schaudinn's collaborator in the discovery, has emphasized this difficulty, and he says that in a stained specimen the diagnosis should only be made by an expert, one who by close familiarity with the organism has acquired an intuitive knowledge of its morphology. It is a fact that the stained specimen lacks some of the characteristics of the living organism, chief of which are: In the stained specimen the organisms are much less numerous than when the same material is examined fresh. The method of preparing the specimen causes the organisms to lose to a certain extent the acute winding of the spirals, which is so characteristic of the living organisms. Probably one of the greatest disadvantages of the stained specimen is the absence of motility. The motions of the spirochætæ are very characteristic and are of inestimable assistance in distinguishing the pale from other spirochætæ. It is much more convenient and reliable to demonstrate the organism in the living state. And here the so called dark ground illuminator adjusted to the microscope are of great The Reichart instrument is the best, because it can be used on any kind of microscope; by means of the revolving diaphragm the amount of light may be varied at will; it is possible to change from the dark ground method to the ordinary method of transmitted light by merely revolving the diaphragm. The method of using the apparatus is as follows: The Abbé condenser is removed. A strong light is necessary; one may use sun or arc light, a Nernst lamp, or an inverted Welsbach. Except with the sun or arc light, a six inch condenser lens is necessary, or a large glass globe filled with water serves the same purpose. The illuminator is placed on the stage of the microscope, and by means of the low power the circle which is etched on the glass plate is brought into the centre of the field and the apparatus fixed in this position by means of the clips on the microscope. A drop of immersion oil, free from air bubbles, is placed on the centre and the prepared slide put in place, great care being taken to avoid the formation of air bubbles. When the preparation is examined with the low power, if the light is placed right and the apparatus centred, one observes a bright central point. The high power is now turned on and the field is seen to be dark, with luminous points and bodies. The authors conclude that the Spirochæta pallida is the true cause of syphilis and its presence is equivalent to the diagnosis of syphilis. Its absence does not rule out syphilis. The silver spirochætæ are true organisms. By means of this method the spirochæta may be demonstrated in all primary and secondary lesions of syphilis, if the search is persistent. After demonstrating the organism in a primary lesion it is not only unnecessary but harmful to wait for secondary manifestations. The most logical therapy is excision of the chancre when possible, and in all cases the immediate institution of the vigorous antisyphilitic treatment.

Fracture of the Patella.-Batchelor states that bony union rarely takes place before thirty days, and that it is possible where there is, after suture, a separation of the fragments equal to three eighths of an inch. Whenever general anæsthesia is directly contraindicated such patients may

be operated upon under local analgesia and bony union confidently expected. The essential requirements of the operation are, first, preliminary fixation of the joint for from forty-eight to seventy-two hours to allow complete arrest of hæmorrhage; second, suture of the lateral tear of the capsule, thereby restoring the reserve extensors and obviating the danger of atrophy of the quadriceps; third, absolute asepsis and immediate closure of the joint without drainage.

11. Mercurial Treatment for Late Syphilis .-Klotz remarks that tertiary or late manifestations of syphilis can usually be as successfully treated by mercury alone as by iodides alone or in combination with mercury. In many instances they are influenced by strong mercurial methods when iodides and mixed treatment have failed. It is therefore advisable, in clearly syphilitic manifestations, not to cease specific treatment, and in doubtful cases not to dismiss the diagnosis of syphilis until such strong mercurial treatment has been sufficiently applied as offered by the intramuscular injections of insoluble mercurial preparations, of which calomel is the most reliable one.

13. Hæmorrhage of the Adrenals in Infants. -Litzenberg and White observe that hæmorrhage of the suprarenal capsules is more common than hæmorrhage in the other viscera. This is due primarily to the close relation of the adrenals to the vena cava, making congestion easy, and to the peculiar anatomical construction which favors hæmorrhage. A weakness of the vessel walls, either normal delicacy or pathological alteration, favors the rupture. The place of election of the hæmorrhage is usually in the internal cortical zone because of its vascularity and the anastomotic arrangement of the vessel. The bleeding always follows active or passive congestion. Passive congestion may be caused by difficult labors, obstetric operations, thrombosis. or, in short, anything that would favor venous stasis. Active congestion is induced by infection or any toxæmia which incites hyperæmia by a superactivity of the gland. The findings of the pneumobacillus of Friedländer in the author's two cases and other bacteria in five additional cases proves beyond question that infection is a cause of adrenalin hæmorrhage. Death results either from loss of blood or an interference with the physiological function of the gland.

MEDICAL RECORD

Overcoming the Predisposition to Tuberculosis and the Danger from Infection during Childhood By S. Adolphus Knopp. True Neurasthenia—Its Nature and Treatment,

By A. D. ROCKWELL The Ultraviolet Ray and High Frequency Currents in Neurasthenia, By Sinclair Tousey.

The Care of the Mouth during Infancy and Child-lood.

Special Provisions for Management of Certain Forms of Mental Disorder,

By ALFRED GORDON.

1. Overcoming the Predisposition to Tuberculosis and the Danger from Infection during Childhood.—Knopf remarks that when a child. because of its delicate constitution, is susceptible to frequent colds, so that one may hesitate to take it much outdoors, it should be borne in mind that fresh.

pure air really does not give colds, and what are commonly known as colds are often an infectious disease due to a specific microorganism which fastens itself more readily on a delicate system. To overcome such so called susceptibility to colds, one should resort to the judicious use of cold water. From the tenth to the twelfth month one should accustom the child gradually to cold baths. The best time to begin is after its daily warm bath. Rub the child a few times with the hands dipped in cold water and then wipe it rapidly. By and by one may begin with cold sponging, and later with a little douche. In the use of cold water it is absolutely necessary that the reaction should follow rapidly. This reaction, as is well known, is manifested by a pleasant warmth perceived by the child, and is made visible externally by a reddish appearance of the skin. Whenever cold water is applied to the skin one will notice at first a certain whiteness or pallor, which is caused by the contraction of the external bloodvessels. The return of the blood to the external surface causes the reddening of the skin. Whenever reaction is lacking or tardy, the advice of the physician should be sought. It goes without saying that a child should always be properly dressed. In order that its lungs may develop to the fullest extent it must not be hindered by restricting garments, particularly not by tight neckwear (constricting collars and bands). Furthermore, it must be remembered that to dress the neck too warmly lessens the power to resist taking cold when there happens to be a change in the atmosphere. The less one is accustomed to bundle up the neck, the more freely will he breathe and the less will he be likely to take cold. When a girl develops into a young woman, one should bear in mind that the tightly laced corset is one of the most injurious garments which can be worn. Not only is free and natural breathing interfered with by this article of dress, but indigestion and disturbances in the circulation follow excessively tight lacing. Anæmia, or poverty of blood, so often observed in young girls, can very frequently be ascribed to this unnatural mode of dress, which does not permit either a free circulation or sufficient oxygenation of the blood.

2. True Neurasthenia.—Rockwell in speaking of the treatment of neurasthenia says that many a neurasthenic has been made worse by the rest cure, while others have suffered by a continuance of work. In no condition is there more need of an intelligent distinction. If there is cerebral excitement associated with physical exhaustion, rest is imperatively demanded. Rest is also to be recommended in cases of the myelasthenic type. For cases of the lithemic type—hearty eaters, who suffer from autoinfection, and whose frequent irritability and unreasonable outbursts of temper distinguish their case from the mild melancholy of the neurasthenic of an entirely different type, work and activity and plenty of it is oftentimes the saving grace. Success in treatment frequently follows very little active medication, and et at times judicious drugging is distinctly called for. While the patient is undergoing the slower process for encouragement and physical methods of treatment, it is good judgment at times and in certain case to cothe and a tain a weak and erratic nervous a ten la uch drugs as seem best fitted to the case in hand. In these case, where occasional

medication seems to be demanded, some one of the various bromides, including zinc bromide, either alone or in combination with belladonna, cannabis indica, etc., according to individual idiosyncrasies, serve a useful purpose. Of all physical methods of treatment, the electrical should be placed first, as it is of positive value in the treatment of neurasthenia. What is lacking, therefore, most frequently, to make good use of this great agent is the power of intelligent differentiation. An anomaly about a neurasthenic is that generally he appears to be well nourished. His functions are often well performed and his appetite excellent. Yet with all this we find him with a nervous system so erratic and unstable that the slightest influence is sufficient so to disturb the vasomotor equilibrium as to cause general nervous disturbance, as manifested in the quickly flushed face, perspiring hands, dizziness, and perverted vision. As its name implies, neurasthenia is a disease of exhaustion and therefore of impaired nutrition, and electrization, not in one form alone, but in many forms, aids powerfully in the restoration of perverted cellular nutrition. The influence of light and heat will often be found useful in neurasthenic cases. Fundamentally the principles on which are based the therapeutics of light and heat are very much the same as govern the application of other physical methods of treatment, and in the toxæmias and the toxic neuroses the therapeutic value of light energy is beyond question. Both the incandescent and the electric arc light are valuable—the latter perhaps more than the former, since, in addition to its calorific and luminous effects, it imparts chemical activities of a distinctive character. While neurasthenia is no imaginary disease, and no appeal to the imagination alone will overcome the profound loss of nerve tone characteristic of it, or rearrange the delicate fibrillary connection of the neurons that may have been disturbed by the constant impact of physical forces, yet mental therapeutics is without doubt an important factor in many cases.

2, 3, and 4. Heredity in Nervous Diseases, Cancer, and Tuberculosis.—Gowers states that the diseases of the nervous system in which the influence of heredity is marked seem to fall in certain classes. One of these consists of the early abiotrophies or cases in which certain systems of structure in the nervous or muscular system system have an essential defect of vital endurance, in consequence of which their life slowly fails. A marked example is presented by the hair follicles of the scalp, in consequence of which early and extensive baldness occurs in father and son. Examples seen in the nervous system are hereditary optic atrophy,

hereditary ataxy or Friedreich's disease, and the various myopathies. By "early" are meant those abiotrophies which begin before the development which coincides with growth is over, and often not many years after birth. A second class includes the hereditary maladies which begin later in life, after the period of growth is over. They present persistent disturbance of function, and are commonly hereditary, but from either side. In the heredoataxy of Marie the symptoms begin about thirty and are fatal in about twenty years. Huntington's chorea begins usually in the senile period of life, but its heredity is well marked, and so is that of Thomsen's disease (myotonia congenita). A third class consists of the so called functional affections, such as hysteria, neurasthenia, and certain cases of insanity and epilepsy. As regards epilepsy, the writer estimates that at least fifty per cent. of the cases manifest a family tendency.—Bashford, discussing heredity in cancer, states that his observations and experiments on mice fail to give even an indication that cancer is inherited. It appears to be very doubtful whether there is transmitted even the power of acquiring the cancerous modification under excitation; and it is not impossible that cancer may be really a late modification of healthy tissue acquired de novo for each individual and in which inherited predisposition plays no part whatsoever. -Latham shows that our knowledge of heredity in tuberculosis is far from complete. The evidence in favor of an inherited predisposition to the disease is not strong enough to make him advise against marriage in the case of persons who have suffered from pulmonary tuberculosis and who have acquired a partial immunity in the process of the arrest of the disease. His general conclusions are as follows: 1. The hereditary transmission of the tubercle bacillus is so infrequent that it is a negligible factor. 2. The incidence of tuberculosis depends in the main on two factors-(a) exposure to infection, which in turn is governed by the dose received and the virulence of the particular strain of bacillus; and (b) the undermining of the resistance of the individual by insanitary conditions and by disease. 3. The more adequate the preventive measures taken in any community the less are the incidence and mortality of the disease. 4. The more adequate the medical treatment—that is, the greater the proportion of persons in whom the disease has been arrested and who have thereby acquired a partial immunity—the less are the incidence and mortality of the disease. 5. As at death we all, or nearly all, show evidence of having at some time been infected with tuberculosis, and as most of us are able to overcome the infection, it is clear that the diminished opportunity for repeated infection, brought about by preventive measures and better medical treatment in this country, cannot wholly account for the diminishing incidence and mortality of the disease. 6. There is some evidence to suggest that the diminishing incidence and mortality of the disease may be in part due to a partial immunity inherited in the course of generations from tuberculous ancestors in whom the disease has been cured. 7. The theory that there is an inherited predisposition to tuberculosis is based upon insufficient evidence.

7. Pancreatitis.-Watson, in discussing the di-

agnosis and treatment of pancreatitis, excludes from consideration those acute cases which closely simulate acute intestinal obstruction, fulminant appendicitis, and the like, and which tend to a fatal issue in forty-eight hours or so if not relieved by operation. He is concerned only with the mildly acute, the subacute, and the chronic forms of inflammation of the gland. Cases can be conveniently divided into two groups: Those in which jaundice is a prominent symptom; and those in which jaundice is absent. A striking point is the protean character of the disease. An advanced case may closely simulate severe or pernicious anæmia. In the earlier stages the clinical features may be simply those of slight indigestion, sometimes associated with neuriticlike pains in the limbs or trunk. Again the chief symptom may be only physical weakness with little or no obvious morbid signs. Progressive cases tend to a fatal issue; many cases of supposed deep seated malignant disease have been in reality cases of pancreatitis. As regards diagnosis, attention is drawn to the following points: I. In cases of jaundice of doubtful origin assistance in the diagnosis is afforded by urinary analysis. (a) A negative pancreatic reaction points against the existence of pancreatitis. (b) In cases of cholelithiasis a positive reaction indicates pancreatitis and is very strong evidence that the stone is impacted at or near cases where cholelithiasis can be excluded and the clinical features point to the existence of organic disease of the pancreas a negative pancreatic reaction points to malignancy. 2. Glycosuria is of some value in the distinctive diagnosis of pancreatitis from malignant disease, this symptom being more common in inflammatory conditions of the gland. 3. The site and distribution of the pain have diagnostic significance. The pain of pancreatic disease is referred to the epigastrium and radiates to the left side; in disease of the gallbladder and the bile ducts the pain is referred to the right hypochondrium and radiates to the right. 4. An acute onset with pain and pyrexia points strongly to an inflammatory infection. 5. Emaciation, anæmia, and asthenia may be present in pancreatitis to an extent equal to that present in advanced malignant disease. The following points are emphasized in connection with pancreatitis unassociated with jaundice: I. In not a few cases of indigestion associated with flatulence, abdominal discomfort or pain having no distinct relation to food, constipation, and in some cases pale fœtid stools, the primary derangement is to be found in the pancreas. In such cases a prominent clinical feature is the occurrence of pain on deep pressure over the region of the head of the pancreas. 2. In some cases of neurasthenia a marked pancreatic reaction is present in the urine. In the early stages of the disease the inflammation subsides under simple remedial measures. The diet should be light, and a rigid milk diet may be advisable. The excretory functions of the skin should be stimulated by an occasional Turkish bath. In the later stages the meals should not exceed three in number and should be as far apart as possible; protein foods should form the staple of the dietary, sugars and starches being restricted. Intestinal irrigations are often of value. Surgical measures are

called for in cases not responding to medical treatment. The operations recommended are: I. Laparotomy and free manipulation of the gland, for the purpose of loosening and breaking down adhesions and lessening tension. Minute calculi may be thus dislodged. 2. Cholecystotomy, simple drainage of the gallbladder. 3. Cholecystenterostomy, permanent drainage of the gallbladder into the intestines. There should be no delay in operating in cases of chronic jaundice due to the presence of stone in the common bile duct. But great caution is necessary in recommending operative treatment in cases unassociated with jaundice, in which the leading features are gastric symptoms, some general constitutional disturbance, a marked pancreatic reaction in the urine with perhaps occasional glycosuria. Medical measures will in many instances suffice to restore the patients and free them from the subsequent serious risks of diabetes.

By PAUL AUBOURG. Rapid Radiography, By PAUL The Cutireaction and the Nervous Reactions, By R. ROMME.

1. Rapid Radiography. - Aubourg describes the technique of his method of radiography for the purpose of reducing the time of exposure from minutes to seconds, a reduction desirable not only on account of the necessary immobility of the patient, but also because of the smaller dose of the radiations absorbed. His article is illustrated by two plates, one reproduced from a radiograph of a case of scoliosis in which the time of exposure was thirty-five seconds, the other from a radiograph of the upper teeth in which the exposure was four seconds.

 The Treatment of Facial Neuralgia before the Congress of Surgery in 1908,

 By L. Landouzy.

 By J. A. Sicard.
- gress of Surgery in 1908, By J. A. Sicard.
 The Axillary Temperature in the Tuberculous, By R. ROMME.
- 1. Typhobacillosis. Landouzy applies this name to one of the forms of acute tuberculosis. One form of this disease presents the picture of a caseous bronchopneumonia, tuberculosis developing for weeks or months, with the same anatomical lesions of infiltration and softening, ulceration, and breaking down of the caseation met with in late stages of ordinary phthisis. This is galloping phthisis. Sometimes the form is that of a caseous pneumonia that causes death before the appearance of ulcera-

tions and cavities. In the second type the evolu-tion is more rapid. The third type is characterized by the typhoid state with continuous fever and splenomegaly without signs of visceral lesions. This last form is that which he denominates typhobacillosis.

2. Treatment of Facial Neuralgia.-Sicard discusses the paper read by M. Morestin before the Congress of Surgery, which he considers a very re markable one, and finally says that one general therapeutic direction is given, that local alcoholization is the primary treatment to be administered to a true facial neuralgia. In case of failure from the difficulty of guiding the needle with certainty to the round and oval foramina, or in case of very frequent recurrence it is useless to try resection of the peripheral nerves, sympathectomy should be performed, directed to the destruction of the root to the base of the brain, between the bulb and the ganglion. It is evident that this last operation cannot be performed without great risk, especially in people who are old, cachectic, or have little power of resistance.

 Pernicious Anæmia
 By K. Reicher. The Cause of Glaucoma,
 Ætiology and Therapeutics in (Concluded),
- Inflammation of the Lungs Produced by the Inhalation of Ammonia.-Lewin states that the inflammation of the lungs induced by certain irritant gaseous or vapor like poisons has great practical and scientific interest. It can be produced by the most heterogeneous inorganic and organic mate-

rials which are used extensively in industrial life. by acids or bases, by aromatic substances, so long as they are volatile, inhalable, and irritant to the mucous membrane on contact. Hence a specific irritant action is unnecessary in order to induce this disease, although the rapidity and the energy, or the local depth of the action, as well as the finer changes in the affected organs, cause differences to appear, according to the inducing group of poisons. inflammation arises without any bacteriological help, and therefore can be produced experimentally in a very short time. He thinks that to the influences that produce it should be added in many cases the chronic inflammations of the respiratory apparatus, with or without suppuration.

5. Wassermann's Reaction in Scarlet Fever .-Rubens asserts that under certain conditions, whether due to the character of the epidemic or to special peculiarities of the antigen, Wassermann's reaction will take place in scarlet fever the same as in syphilis, while normal serum checks hæmolysis either not

at all or in a small percentage.

6. Complete Lateral Displacement of the Viscera.-Smirnoff describes a case of this nature met with in a man forty years of age.

7. The Cause of Glaucoma.—Levinsohn's explanation of the cause of glaucoma is the one usually accepted, the occlusion of the excretory passages from the anterior chamber.

8. Pernicious Anæmia.—Reicher reports four cases of pernicious anæmia which seem to have been improved by treatment with cholesterin.

 Achelia,
 By Boas,
- 10. Carcinoma Ventriculi ex Achylia, 11. Carcinoma Ventriculi ex Achylia, By EHRLICH. 12. To O. Schmiedebergs on his Seventieth Birthday By MEYER
- Tuberculin Immunity. Hamburger says that in many cases the artificially produced tuberculin immunity depends on a forced inability to react through saturation with antibodies, but it is doubtful whether all cases of such immunity can be explained in this way.
- 3. Marmorek's Serum in the Treatment of Surgical Tuberculosis.-Strauss concludes from his experiences in thirty-seven cases that Marmorek's serum introduced by the rectum is harmless, that in a certain number of cases it seems to exert a beneficial influence which is comparable with the influences of other hygienic and dietetic regulations. Consequently the serum is worth a trial as an additional help in the struggle against surgical tuber-

culosis and should be used in addition to other therapeutic means so far as its price will permit. In cases of extensive infection, tuberculosis of the lungs and other organs, the action of the serum is very uncertain, yet a trial of it seems to be justifiable in these cases also.

6. Casuistics of Tumors of the Skull .-- Klostermann describes an enormous fibrosarcoma removed from the right side of the head and face of

a woman, sixty years of age.

8. Rapid X Ray Exposures.—Gilmer illus trates his article with reproductions of fifteen radiographs taken by exposures varying from one half to five seconds. They are full of detail, in this way far superior to many x ray pictures produced by the usual method of longer exposure. The subjects shown, with the length of exposure, are fracture of the basal phalanx of the great toe, one half second; normal elbow joint, two seconds; fissure of the tibia, two seconds; resected knee after healing, three seconds; tuberculous coxitis, five seconds; tuberculous disease of the second lumbar vertebra, four seconds; impacted fracture of the neck of the femur. five seconds; probe in the sphenoidal sinus, three and one half seconds; normal base of the skull, four seconds; fracture of the radius with breaking off of the styloid process of the ulna, one half second; normal lumbar segment of the spine and promontory, four seconds; normal knee joint, three seconds; empyema of the frontal sinus and ethmoid. five seconds; fissure in the greater tuberosity of the humerus, two seconds.

9. Clinical Casuistics from Practice.-Erb continues his discussion of syringomyelia and dystrophia with the report of three cases, one of dystrophia muscularis progressiva with unusual localization, one of dystrophia muscularis progressiva with unusual localization in the muscles of the neck, and one of dystrophia muscularis progressiva where

the patient recovered.

11. The Ricin Method of Jacoby-Solms for the Quantitative Estimation of Pepsin, Be E. H. Gossman.

1. Gallstone Disease.—Deaver thinks the medical treatment of gallstone disease is most unsatisfactory. Dissolving gallstones or absorbing adhesions by medical means is an almost impossible task. Treatment at Carlsbad hastens convalescence from

gallstone operations, and for those who refuse to be operated upon it will often bring peace of mind. Cases suitable for prophylactic treatment, in the author's experience, are those which have been seen early in the disease. Undeveloped gallstones or other morbid substances, in such cases, can sometimes be drained away. After gallstones have formed, the risk of operation is the risk of delay. The principles which should govern operations on the biliary passages are getting into the abdomen as quickly as possible, remaining there as short a time as possible, getting out as soon as possible, and doing only that which seems necessary to restore the patient to health. The operative field must be carefully walled off by gauze, and adhesions avoided if not interfering with the operation. All stones found in the biliary tract must be removed, drainage usually is efficacious, and postoperative treatment must be watchful and intelligent. Cholecystectomy is avoided when possible.

2. Ascites in Typhoid Fever. - McPhedran thinks that peritoneal effusion in typhoid fever, apart from peritonitis, is of rare occurrence. He has observed six cases in the past three years, in all of which the effusion occurred during the course of the illness, persisted from ten days to two weeks, and disappeared, in all but one of the cases, with convalescence. In only one of the cases was there hæmorrhage or symptoms of peritonitis. of the cases the effusion was due to pathological conditions resulting from typhoid infection, though the immediate cause was uncertain. The relaxed condition of the abdominal walls favored stasis and serous transudation. The enlarged mesenteric glands may also have caused sufficient irritation of the peritonæum to produce effusion. The element of toxemia must also be taken into account, a toxic substance possibly so affecting the hepatic cells as to obstruct the portal circulation, or so changing the peritoneal epithelium as to permit a more rapid escape of serous exudate, causing such obstruction to the peritoneal lymphatic vessels that the exudate may not be readily removed.

4. The Pharmacology of Heart Stimulants.—Wood limits his paper to the digitalis group. He notes three essential factors in the action of these drugs which interest clinicians: (1) The stimulant influence upon the cardioinhibitory mechanism, which prolongs the diastole and slows the pulse; (2) the increased tonicity of the heart muscle leading to more complete systole; (3) the constriction of the bloodvessels. The slowing action of digitalis is more beneficial in heart disease than is generally supposed. Especially in chronic heart disease is the inhibitory stimulation of digitalis beneficial in its effect, and in no portion of the heart is this beneficial action felt to the same degree as in the left ventricle. It has also a valuable vasoconstricting influence which has sometimes been regarded as a harmful by effect. Besides digitalis the author considers the utility of strophanthus, squills, apocynum, and adonidin. Squills and apocynum are seldom used, owing to their irritant action. The action of strophanthus upon the vessels is less powerful than is that of digitalis, but it is less likely to give rise to cumulative toxic symptoms. The effect of adonidin is similar to that of digitalis upon the heart muscle and upon cardiac inhibition, but less powerful. When merely the cardiac action of the digitalis group is desired in chronic heart weakness, none of the members of this group will compare with digitalis itself,

6. The Interpretation of the Venous Pulse .-Bachmann states that the physiological or so called negative systolic venous pulse consists of three positive and three negative waves, bearing a more or less definite relation to the events of the cardiac cycle, and having their origin in the various movements of the chambers and structures of the right heart. The first positive is presystolic, the contraction of the auricle slowing the venous current and producing a centrifugal wave. The second positive is protosystolic and caused by the sudden projection of the tricuspid valve into the cavity of the auricle. The third positive at the end of ventricular systole is due to relaxation of the papillary muscles causing an upward movement of the tricuspid leaflet and the return of the auriculoventricular sæptum to the position of rest. The first negative is due to the relaxing auricle, the second occurs during the diastole of the auricle, and is due to the dilatation of its walls, the displacement of the auriculoventricular sæptum toward the apex and the pull of the papillary muscles on the tricuspid valve leaflets. The third negative appears during ventricular diastole and in the common pause of the heart chambers. It is caused by the passage of the blood from the auricle into the ventricle.

8. The Diagnostic Value of Cutaneous Hyperalgesia in Abdominal Disease. - Elsberg and Neuhof summarize their paper as follows: I. They agree with Head, in general, that there are present in many diseases of the abdominal viscera constant and definite areas or zones of cutaneous hyperalgesia. 2. These zones may vary in extent and outline, but have a characteristic location. 3. The presence of a characteristic zone is an evidence of a disease of the corresponding abdominal viscus, though not necessarily the disease which causes the symptoms. 4. These zones occur in most of the patients with acute affections of the appendix, the gallbladder, the uterine annexa, and are of value in the diagnosis of these acute affections. 5. They are frequently present in acute disease of other abdominal viscera and may aid in making the diagnosis. 6. Cutaneous hyperalgesia may occur early in acute abdominal disease. Its presence does not indicate the gravity of the lesion. Its sudden disappearance may have great significance. 7. In the absence of other localizing signs the zone may indicate the organ that is affected. It is usually to be regarded only as a diagnostic aid.

 14. Surgical Progress. Excerpts from Transactions of

the German Congress of Surgery, 1908, Translated by J. T. Pilcher and W. Joerg.

The Use of Ethyl Chloride as a General Anæsthetic in the Pennsylvania Hospital.-Lee finds records of the use of this substance in the hospital referred to in 5,575 cases from December, 1902, to June, 1908, the duration of anæsthesia varving between a few seconds and fifty-four minutes, and the average dosage for three minutes being ten grains. The administration is usually by the drop method upon a few layers of gauze held as near the face as may be necessary. After the occurrence of deep anæsthesia, should the eyeballs become fixed, the pupil dilated and immobile, the corneal reflex disappear, and the face be flushed and covered with perspiration, the danger line has been reached. Should death result it would be due primarily to respiratory and secondarily to cardiac failure. Should ether be substituted for ethyl chloride, in a given case, the change should be made gradually that the anæsthesia may not be interrupted. Thus far twentyfive fatal cases have been reported from the use of ethyl chloride, its mortality being slightly greater than that of ether. The caution is sounded that a substance which will cause deep anæsthesia in fifteen to twenty seconds, and whose danger signs are so easily passed, cannot be used with impunity. Its many advantages will cause its continued use, though with more and more watchfulness.

3. Tumors of the Breast in Childhood.-Jopson, Speese, and White offer the following conclusions: Tumors of the breast, though rare in childhood, occur in both sexes and at all ages. Benign tumors in the young are more common in the mammary gland than the malignant, the most common varieties being fibroepithelial growths and angiomata. Sarcomata are rare and carcinomata almost unknown before puberty. Girls are less often affected than boys, but the difference is not so great as in adults. Angiomata are usually congenital or appear in infancy, fibroadeomata develop as puberty is approached. The smaller benign tumors may cause no inconvenience, or they may give rise to pain, tenderness, and inconvenience on account of their size. Sarcomata show the symptoms usual with that form of tumor. Operation is usually indicated in the benign and always in the malignant varieties. Conservative plastic operations may be performed for small benign tumors, but in many of the cases the breast must be sacrificed. Enlarged glands in the axilla must be removed. The results of operations

have been good.

9. Some Surgical Conditions in the Knee Joint .- Tenney concludes his paper with the following propositions: 1. Asepsis and drainage are more essential in knee joint work than in abdominal surgery because of the difference of the skin in the operative fields, and in the natural drainage of the two cavities. 2. Sepsis and immobility mean ankylosis. Drainage and mobility may leave some motion. 3. There is increasing tendency to operative repair of patella fractures and increasing use of absorbable material. 4. The most common mechanical cause of trouble with the joint is the tab from the infrapatella pad. This may be an element in a general obesity which may demand appropriate antifat treatment. If it is present in a vigorous person it should be removed. Temporary relief may be obtained from properly applied adhesive straps, but a cure will come only from removal. 5. Prepatella bursitis may be cured by incision and drainage. Other bursæ should be dissected out. 6. Ligamentous injuries must be carefully treated and some must have operative repair to prevent recurring disability. No apparatus is so good as a normal knee.

Proceedings of Societies.

SIXTH INTERNATIONAL CONGRESS ON TUBER-

Held in Washington, D. C., September 28, 29, and 30, and October 1, 2, and 3, 1908. (Continued from page 1104.)

SECTION III.—SURGERY AND ORTHOPÆDICS. (Continued from page 912.)

Tuberculous Arthritis of the Hip Joint .- Dr. STEPHEN H. WEEKS, of Portland, Me., said that the great principle of local treatment in tuberculous arthritis of the hip was to rest the affected joint. This end might be secured by extension, by fixation, or by a combination of both. The constitutional treatment consisted first of all in strengthening the defensive mechanism of the body to combat the infection. The well known methods to increase the resistance of the patient were sunlight, fresh air, and proper nutrition. All that could be said about the treatment by bacterial vaccines was that it might prove a valuable adjunct to other

The Treatment of Tuberculous Hip Disease by Weight Bearing and Fixation by the Lorenz Short Hip Spica .- Dr. H. Augustus Wilson, of Philadelphia, said that weight bearing was conducive to the benefits afforded by outdoor life in the treatment of tuberculous arthritis of the hip, because the activity allowed by the method prevented circulatory stasis. On the other hand, confinement and inactivity favored atrophy from disuse. Weight bearing without fixation, under the most favorable circumstances, might result in recovery, but with ankylosis in deformed postures. Weight bearing with the Lorenz short hip spica facilitated the employment of outdoor life and shortened the time of the treatment. In some cases treatment by this method was followed by the rapid recovery from abscesses, and by slow and permanent recovery in other cases. The most favorable posture was that of 20° of abduction, 20° of flexion, and 5° of external rotation. The method was not applicable to debilitated patients without the temporary assistance of crutches.

Vaccine Therapy in Joint Tuberculosis .- Dr. EDWARD H. OCHSNER, of Chicago, said that the treatment of a tuberculous joint with a bacterial vaccine should never be undertaken without the control of a careful reading of the opsonic index. It should always be associated with other recognized methods of treatment, such as fresh air, immobilization of the joint, and measures to prevent the occurrence of secondary infection. If it was employed in that manner, a considerable percentage of perfect anatomical and functional cures could be obtained, because the vaccine treatment secured healing with a minimum amount of connective tissue formation.

Tuberculosis of the Bladder .- Dr. WILHELM KARO, of Berlin, said that tuberculosis of the bladder was almost always a descending process of hæmatogenous origin, usually dependent upon renal or genital tuberculosis. He found that the mode of infection influenced the position of the tuberculous lesions in the bladder. For instance, if the primary lesion was situated in the left kidney, the bladder lesion would be near the left ureter. chief symptoms of tuberculosis of the bladder were difficult micturition, hæmaturia, and pyuria. diagnosis was made by finding the tubercle bacilli in the urine, directly or by inoculation into ani-It was important to discover the primary seat of the lesion in every case of genital tuberculosis, employing either the cystoscope or catheterism of the ureters. The picture presented on cystoscopic examination was not absolutely characteristic, since nontuberculous disease sometimes preduced nodules. The surest prophylactic measure to prevent tuberculosis of the bladder was early extirpation of the diseased kidney, before involvement of the bladder had taken place; hence the prognosis of bladder disease depended upon the operability of the case. In the great majority of cases spontaneous recovery of the bladder followed the removal of the primarily diseased kidney. case the bladder symptoms failed to clear up, it indicated the involvement of the other kidney. systematic tuberculin cure was the most suitable treatment for such a case, with supplemental local treatment with weak mercuric chloride solution. Direct surgical treatment of a tuberculous bladder was to be deprecated.

The Surgical Bearings of Tuberculin.-Dr. R. W. Phillip, of Edinburgh, said that tuberculin was a valuable agent in conservative surgery. It might replace an operation in an obscure case, when the topical diagnosis was not exact or when the operative procedure was doubtful. Tuberculin was also of value in inoperable cases, such as, for example, cases of extensive genitourinary tuberculosis.

Surgical Tuberculosis.—Dr. E. H. BRADFORD, of Boston, said that the treatment of tuberculosis was dependent for its ultimate results upon the establishment of an immunity which would protect the patient from further tuberculous invasion. This was the desired goal, whether or not the tissues attacked were accessible to surgical interference. When the tissues in which the tubercle bacilli were growing were placed under suitable conditions, healing took place and a cicatrix resulted. The detritus of the diseased tissues either was thrown off or became encapsulated. In tissues in which it was possible to do a radical operation for their removal, the surgeon decided whether the healing process would be hastened by such removal of the infected area or the detritus of the infected area. The decision was made by taking into consideration the tissues affected and the anatomical relations of the affected parts. These considerations were particularly important in tuberculosis of the bones and of the joints, because bone was a tissue that cicatrized slowly, and because the joints were especially exposed to injury, which was unfavorable to the healing of the tissues infected by the Bacillus tuberculosis. The treatment of surgical tuberculosis, then, consisted in protecting joints, operative interference, and the employment of such measures as would be useful in combating tuberculosis in general.

The Surgical Treatment of Tuberculous Sinuses and their Prevention .- Dr. EMIL G. BECK, of Chicago, said that the successful treatment of tuberculous sinuses depended upon a careful anatomical diagnosis. The boundaries and all the ramifications of such a sinus could be shown by radiographs obtained by injecting the fistula with a thirty-three per cent. bismuth-petrolatum paste, which was liquefied by heating and which quickly solidified after the injection. The injection of this paste was of great value in the treatment of these sinuses, and also in the treatment of abscesses and empyema. Cases which had resisted the most skilful treatment for years had ceased suppurating and had healed within a few weeks after the commencement of the injection with the paste. If there was a sequestrum at the bottom of a sinus in a leg or an arm, it would be necessary to remove it before employing the paste. Bismuth subnitrate was an ideal drug for the treatment of such lesions, because it was bactericidal, slowly absorbed, and practically nontoxic. For the prevention of the development of fistulous tracts the speaker advised the opening of cold abscesses as soon as they pointed, evacuating the pus and at once filling the abscess cavity with a ten per cent. bismuth-petrolatum paste, and not sealing the opening. treatment prevented secondary infection, which formerly was given as a reason for not opening tuberculous abscesses.

Fresh Air Combined with Hyperæmic Treatment in the Management of Complicated Surgical Bone Tuberculosis in Adults.-Dr. WILLY MEYER, of New York, said that the beneficial influence of fresh air in surgical bone tuberculosis in children was generally recognized. In adults, on the other hand, the beneficial influence of fresh air was not so thoroughly recognized, although the open air treatment was of nearly as much importance in adults as it was in children. Of course, when the saving of time was a factor, a radical operation was the method of treatment to adopt. The speaker recommended that wards be set aside in sanatoria for the treatment of tuberculosis for the accommodation of adults, suffering from tuberculosis of bones, who for any rea-

son could not be subjected to operation.

The Importance of and the Method Used by the State of Minnesota for its Indigent Children Suffering from Tuberculosis of the Bones and the Joints.—Dr. ARTHUR J. GILLETTE, of St. Paul, said that the legislature of the State of Minnesota appropriated money for the care of indigent and deformed crippled children in 1897. Three quarters of these patients were suffering from bone or joint tuberculosis, and many of them had pulmonary or intestinal tuberculosis. Others had abscesses and running sores which contained the Bacillus tuberculosis and other infecting organisms. Many of the children attended the public schools, and no provision was made to protect the noninfected children. The patients had to be educated as well as treated for their bone and joint tuberculosis. The State of Minnesota undertook to treat these patients and to educate them at the same time, providing the means for the instruction of its wards in a line of work which should be useful to them in later years.

Section IV.—Tuberculosis in Children.

Dr. Abraham Jacobi, of New York, in the chair.

Tuberculosis in Infants: An Analysis of 130 Hospital Cases as Regards Ætiology and Diagnosis, with Remarks upon Prevention and Treatment.—Dr. LINNEUS EDFORD LAFETRA, of New York, reported the results of the study of 130 cases of tuberculosis in children, all under three years of age, the majority of them being less than one vear old. In nearly one half of the cases of pulmonary tuberculosis the mother, the father, or some one else who came in close contact with the patient suffered from tuberculosis, almost invariably pulmonary. The same was true of the patients suffering from tuberculous meningitis. In the meningeal cases, more than one half of the patients had pulmonary tuberculosis in addition to the meningeal lesion. In the majority of the cases of pulmonary tuberculosis in very young children it was impossible to make a diagnosis from the examination of the chest. In some cases there were no physical signs, in others râles could be detected, while others showed the signs of bronchopneumonia or of lobar pneumonia. Very few of the patients presented the signs of consolidation or of cavity formation. For an absolute diagnosis tubercle bacilli must be found in the sputum or the lesions must be seen. In young subjects a positive skin reaction to tuberculin was considered almost certain. If a careful sputum examination and the skin test were both negative one could feel safe in ruling out tuberculosis. Of the seventy-three pulmonary patients, thirty-four died, twenty-nine were unimproved, and ten were improved. Four of the patients seemed to have recovered completely, with no signs in the lungs from one to two years after leaving the hospital. From the viewpoint of prophylaxis the father and the mother in a tuberculous family should be warned before the birth of a child that tuberculosis is communicable to the child by close contact, especially by nursing a tuberculous mother, and by kissing. The infant should be isolated as completely as possible from the afflicted person; it should be prevented from crawling on the floor, unless there was some method of washing the rugs used in the house. The

usual hygienic measures should be enforced. Milk from untested cattle should be sterilized. All the children in a tuberculous family should be examined at intervals for the presence of physical signs of tuberculosis and for the tuberculin skin reaction. Suspicious cases should be put under active treatment at once, in a country home, a forest school, or a sanatorium. Persistent coughs in infants should be actively treated so as to prevent the development of tuberculous meningitis.

The Relation of the Infectious Diseases-Measles, Whooping Cough, and Influenza-to Tuberculosis in Children .- Dr. EDGAR P. COPELAND, of Washington, said that measles, whooping cough, and influenza were looked upon by the public as not being very serious, but the diseases were widespread, and, although tuberculosis followed them as a complication and a sequel, it was difficult to determine the number of cases in which tuberculosis developed after an attack of one of the other infec-Autopsy statistics showed that tuberculous lesions were present in 31.2 per cent. of all cases of death from measles. The catarrhal inflammation of the mucous membranes, associated with hyperæmia and lymphatic activity, were common to all of the diseases, and this was the key to the relation between them. Lymphatic activity was the determining factor in the dissemination of tuberculosis through the body. Following influenza and whooping cough there was usually a general miliary tuberculosis in which the pulmonary symptoms predominated. Influenza was seldom followed by tuberculosis except when the latter disease was already latent in the body. Taking into consideration the prevalence of measles, whooping cough, and influenza, tuberculosis did not follow them sufficiently often to be of very great importance. Its develop-ment in nearly all cases was the result of a latent focus of the disease. Its dissemination was due to lymphatic activity.

Miliary Tuberculosis in a Child Aged Four and One Half Months.-Dr. A. L. Kotz and Dr. E. M. GREEN, of Easton, Pa., reported the case of a female child who was born in December, 1907. At the age of two weeks she was fed on cow's milk. At the age of four weeks she was given modified certified The child gained steadily until she was twelve weeks old, when she gradually lost flesh. Her temperature averaged 99.4° F.; her abdomen was much distended; and she died when she was four months and a half old. At the autopsy it was found that there were two small tuberculous nodules in the lungs, and that one or two of the mediastinal lymph nodes were involved. The peritoneal cavity was completely obliterated, the intestines being firmly glued together. The tuberculous lesions consisted of masses of tubercles fused into flat, yellowish masses of the size of a pea. These masses were very numerous in the pancreas. In the intestines the tubercles were found in the serous and subserous coats in great numbers. The muscular coat and the mucosa were atrophied and were infiltrated with small round cells. Tubercle bacilli were present in these lesions. They were shorter, thicker, and less beaded than the ordinary bacilli found in human tissue. Investigation showed that the farm from which the first supply of milk for this child had been obtained had had one or two infected Jersey

cows. The certified milk had come from an inspected herd in which no infected cows were discovered. The child had been infected during the third and fourth weeks of life so violently that death occurred

about three months later.

The Relative Frequency of Abdominal Tuberculosis in Great Britain and the United States .-Dr. DAVID BOVAIRD, JR., of New York, said that he had discovered, during an investigation conducted in 1901, that there was a remarkable discrepancy between the figures for primary intestinal tuberculosis in Great Britain and in the United States. This difference was real, and was not due to a difference in the interpretation of findings, as was evidenced by the clinical data concerning abdominal tuberculosis in children in these countries. The term abdominal tuberculosis was intended to include tuberculosis of the intestines, the mesenteric lymph nodes and the peritonaum. Data obtained from hospitals in Edinburgh, Glasgow, and London, compared with those from the hospitals of New York and Boston, showed that all forms of tuberculosis were much less frequent in the United States than in Great Britain. On the other hand, abdominal tuberculosis was disproportionately frequent in Great Britain. This contrast was sufficiently great to indicate that some special condition must be present to determine the unusual frequency of abdominal tuberculosis in Great Britain; but an investigation into the incidence of bovine tuberculosis in Great Britain did not substantiate the suspicion that bovine tuberculosis was the cause of it. The writer assumed that abdominal tuberculosis represented the frequency of alimentary tuberculous infection. In the United States abdominal tuberculosis was most frequent in the later years of life, not in the first two years, when cow's milk was most used as food.

Tuberculosis of the Pericardium in Children.-Dr. Joseph S. Wall, of Washington, said that tuberculous pericarditis was a distinct morbid entity and that it produced a definite train of clinical symptons. On the other hand, cases in which the disease was latent, occurring as a complication of tuberculous disease in other parts of the body, might be called tuberculosis of the pericardium. The distinction between the two conditions, however, was merely one of degree. There was an atiological influence produced by the infectious diseases of childhood which was probably due to the enlargement of the mediastinal lymph nodes which followed them. Tuberculosis of the tracheobronchial and peribronchial lymph nodes, with extension of the disease to the pericardium by continuity and contiguity, was the most important ætiological factor. The disease might be plastic or there might be exfrequently hamorrhagic. In some cases adherent pericardium resulted from a lesion which did not end fatally. He reported two cases in which autopsies had been done.

Children of the Tuberculous.—Dr. THEODORE B. SACHS, of Chicago, said that he had examined 322 children of tuberculous parents of the laboring class who were living in surroundings favorable to the transmission of the disease. Twenty-nine per cent. of all the children showed positive evidence of the disease. Among those children born before

the parent became tuberculous, twenty-eight per cent. were tuberculous, and among those born after the parent became tuberculous, thirty-one per cent. were infected. The difference was ascribed to closer contact with the infection in the more crowded surroundings into which the family drifted with the abridgement of the working capacity of the parent.

(To be continued.)

Book Antices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

The Medical Record Visiting List, or Physician's Diary, for 1909. New, Revised Edition. New York: William Wood & Co.

This diary appears in two editions, for sixty patients a week, and for thirty patients a week, both with or without dates. Besides this visiting list, the diary contains the usual addenda, such as approximate equivalents of temperature, weight, capacity, measures, etc.; maximum doses in apothecaries' and decimal terms; artificial respiration; signs of death, etc.

Pulsating Exophthalmos. Its Ætiology, Symptomatology, Pathogenesis, and Treatment. Being an Essay based upon an Analysis of Sixty-nine Case Histories of this Affection. By George E. De Schweinitz, M. D., Professor of Ophthalmology in the University of Pennsylvania, and Thomas B. Holloway, M. D., Instructor in Ophthalmology in the University of Pennsylvania. Philadelphia: W. B. Saunders Company, 1908.

This essay, an elaboration of a paper by the same authors, aims to compare the therapeutic measures, surgical and others, which have been employed in the treatment of the cases analyzed, and to find a procedure of choice. Particular consideration has been accorded to the orbital operations for the relief of exophthalmic goitre. The observations and conclusions of these well trained and careful observers will be of service, not only to the ophthalmologist, but to the clinician and surgeon as well.

Pathogenic Microorganisms, including Bacteria and Protozoa. A Practical Manual for Students, Physicians, and Health Officers. By William Hallock Park, M. D., Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College. Assisted by Anna W. Williams, M. D., Assistant Director, Research Laboratory, etc. Third Edition, Enlarged and Thoroughly Revised. New York and Philadelphia: Lea & Febiger, 1908. Pp. viii-642.

This is one of the best bacteriologies in the English language, and should find a place in every physician's library. It is difficult to select any particular portion of the book for commendation, but certainly chapter xiii, dealing with the relation of bacteria to disease, is especially well worth careful study. In a way this strikes the keynote of the book, namely, to give the reader the practical applications of bacteriology to medicine. The chapter on diphtheria covers forty-two pages, and is a mine of information. The chapter on the typhoid colon group of organisms is not so clear as it might be. Thus, on page 260 three types of intermediates are mentioned. After describing the first two types, the authors do not describe the third, the psittacosis type. Paraty-

phoid infection is discussed under the intermediates, page 269, and again under the typhoid bacillus, page 305. The bacteriology of milk is very well discussed, and the importance of cleanliness and rapid cooling is clearly set forth. The chapter dealing with rabies should be read by physicians everywhere. The smear method of diagnosis, now used in the laboratory of the New York City Health Department, is so simple that with some practice it can be performed by any practising physician with moderate laboratory training. There is also a good presentation of Pasteur's treatment of rabies. Altogether this book is a credit to American medical science.

The Extra Pharmacopaia of Martindale and Westcott.
Revised by W. Harrison Martindale, Ph. D., F. C. S.,
and W. Wynn Westcott, M. B. (London), D. P. H.
H. M.'s Coroner for Northeast London. Thirteenth
Edition. London: H. K. Lewis, 1908. Pp. xl-1164.
(Price, 10s. 6d.)

By the use of a thinner paper and smaller type for matter that is not frequently referred to, the revisers of Martindale and Westcott's Extra Pharmacopæia have been enabled to present a volume of smaller size than the preceding twelfth edition, but with an addition of 128 pages. Having run through so many editions since it first appeared, in 1883, the book is familiar enough to physicians and others making use of it to make it unnecessary to describe it in detail. It is sufficient to say that the work has been brought thoroughly abreast of recent progress in medical science, and many novelties in materia medica are included in this edition. As a convenient reference book for new chemicals, drugs, and modes of treatment, it is unsurpassed. It is difficult to name a drug or preparation used in medicine which is not enumerated and described in its pages, and a very excellent index and posological table aid considerably in the work of finding titles. The bibliographical references have always been a commendable feature of the book. Where abstracts from the literature may be deemed too condensed by the searcher after information, the reference to the volume or periodical from which the abstract was made will enable him to consult the original article in its entirety. The high standard of excellence in its abstracts which has always characterized Martindale and Westcott's work is fully maintained in the present edition, and it is a pleasure to reiterate previous words of commendation for the book, which is an indispensable one for the practising physician who still retains his belief in the efficacy of therapeutic measures.

Gynacciogy, and Abdominal Surgery: Edited by Homason A. Kelly, M. D., F. R. C. S. (Hon. Edin.), Professor of Gynaccological Surgery at the Johns Hopkins University; Gynaccologist to the Johns Hopkins Hospital, Baltimore; and Charles P. Noble, M. D., S. D., Clinical Professor of Gynaccology at the Woman's Medical College, Philadelphia; Surgeon in Chief, Kensington Hospital for Women, Philadelphia, Illustrated by Hermann Becker, Max Brödel, and others. Volume II. Philadelphia and London: W. B. Saunders Company, 1908. Pp. iv-862.

As a scientific production this volume is distinctly superior to its predecessor, possibly because it takes up the newer problems of abdominal surgery, while little has been added to the essentials of gynæcology since Gaillard Thomas wrote his epoch making work, twenty years ago and more. The range of

subjects which is covered by this book is a large one, and the writers are the masters in their line. In addition to the distinguished editors, one need only mention the names of Murphy, Ochsner, Moynihan, Opie, Finney, Williams, and the others. While a work by a variety of authors lacks harmony as a literary production from the very variety of literary styles, this objection may certainly be waived from the almost uniform excellence of these papers—short treatises they may be considered.

We have seen no description of the surgical diseases and operations upon the liver and gallbladder which can surpass the excellent one by Ochsner in this volume, and the illustrations leave nothing to be desired in the way of luminosity of demonstration. The same may be said of the comprehensive treatment of intestinal surgery by Murphy.

An interesting discussion is that upon the use of drainage in abdominal and pelvic surgery, which, however, produces no convincing proof, pro or con, except that drainage as a principle is an invaluable one, which may be applied according to the conviction or the prejudice of each individual operator.

We know of no good reason why the "surgery of the pancreas" and "surgical treatment of diseases of the pancreas" might not have been comprised in a single article, or why "hernia" and "operations for inguinal hernia" might not have been condensed in the same way. Occasional obscurities of style might have been remedied by the editors. As a point of mechanical importance, it would seem desirable that so large and heavy a book should have an unusually substantial binding. One who is so fortunate as to own the book will desire to consult it frequently, and the binding would suffer.

Cataract Extraction. Being a Series of Papers, with Discussion and Comments, Read before the Ophthalmological Section of the New York Academy of Medicine, 1907-1908. Edited by J. HERBERT CLAIBORNE, M. D., formerly Adjunct Professor of Ophthalmology, New York Polyclinic; Instructor in Ophthalmology, Cornell University Medical College; Surgeon, New Amsterdam Eye and Ear Hospital. New York: William Wood & Co., 1008.

This series of essays, read before the Ophthalmological Section of the New York Academy of Medicine during the year the editor served as its president, forms a very pleasant memento to all who took part in the proceedings at that time. Each essayist was requested to devote himself to a certain topic, but naturally the writers stray into each others' territory more or less and present personal views, and this gives perhaps to the collection its principal advantage over any book written by a single author. The most valuable contribution by any one essayist is possibly the report by Dr. Lambert of the results obtained in two patients by the Fukala operation, made in the chapter on Extraction of the Artificially Cataractous Lens in High Myopia. Novelties in procedure are presented by Dr. Claiborne in chapters vi and xi, Extraction of Cataract with a Lance Shaped Keratotome, and A New Procedure for the Artificial Maturation of Cataract. It seems a pity that Major Smith's operation for extraction in the capsule is dismissed with so few words, but at the time the essay was written very few of us were familiar with the technique, which differs widely from that of the usual operation, or

had enjoyed the good fortune to see it properly performed. As a class the essays are creditable to their authors, and the collection is one we are glad to commend.

The Muscles of the Lyc. Vol. II. Pathology and Treatment By Lucien Howe, M. A., M. D., Professor of Ophthalmology, University of Buffalo, Member of the Royal College of Surgeons, England, etc. New York: G. P. Putnam's Sons, 1908.

The second volume of Howe's monumental work amply fulfils the promise of the first section, on the anatomy and physiology of the ocular muscles, giving, as it does, an authoritative, instructive, and practical survey of the entire field of the pathology and treatment of ocular motor anomalies. chapter on operations on the eye muscles is unusually complete and clear. The question of ocular palsies due to lesions in the brain or in the nerves is considered at length. A short chapter is devoted to atypical movements, including nystagmus, and it is to be hoped that the author will at some future time give us a more detailed study of the last topic. The illustrations are of rather un-Greater uniformity of scale and even merit. method would have added to their attractiveness as well as to their demonstrational value.

Miscellany.

Dr. Henry Denton Nicoll.—In the recent death of Dr. Nicoll on October 26th at New Windsor, New York, in the sixty-fifth year of his life, there has been removed from the medical profession of New

York city one of its leading practitioners.

His active work in the Woman's Hospital, with which he was connected for thirty years as visiting surgeon and as consulting surgeon, also his valuable services in the organization and administration of the New York Infant Asylum, will make his loss keenly felt by both of these institutions.

During the last few years of his life Dr. Nicoll had to an extent retired from active practice, though still giving unstintingly to the above institutions his ma-

ture counsel and warm interest.

During these later years he enthusiastically joined with others in the vicinity of his country home at New Windsor, N. Y., in surrounding the young men and young women of that locality with elevating and refining influences. In such a capacity he was the president of the Law and Order League of New Windsor Township, and in the village of Moodna, near his country home, he built a chapel, the centre of the practical uplifting and of the moral work of the community.

At a recent special meeting of the Medical Board of the Woman's Hospital in the State of New York, the following resolutions were unanimously adopted:

Resolved. That in the death of Dr. Nicoll the Woman's Hospital has lost one who uniformly placed its interests above that of self, considering at all times its welfare.

That in the loss of his prudent, conservative counsel the Medical Board feel deeply his death, and recognize that in his faithful administration of the office of president it has lost a devoted friend, a wise adviser, and one whose influence has been and will be felt throughout the Hospital.

That, as a small token of our love and admiration for our colleague, we present this to the Governing Board of the Hospital and direct that a copy be sent to the medical journals of New York city for publi-

cation and also to the family of Dr. Nicoll.

(Signed)

CLEMENT CLEVELAND, B. MCE. EMMET. P. F. CHAMBERS, J. RIDDLE GOFFE, LEROY BROUN, AUSTIN FLINT, JR.

The Town Physician.

Uncle Bill?—what!—he fifty!
Now come all ye thrifty—
Ev'ry man his voice left—he
Must sing high and loud:
Give a rouse, lads,
Give a rouse, lads,—
Ev'ry heart in the crowd!

Country doctor, this man is; Drugs and laughter his plan is; Babes, farmhands, and grannies Testify to his skill:—
Mother and man, sir.
They will answer
With a cheer and a will.

He's as brown as the heather:— Fun, hardship, and weather All working together Have seasoned his age To the queerest And dearest Antic boy and grown sage.

Up he'll get in the night time,— Drop his axe in the light time— Any time is the right time— To heed the poor's call— Even when he's Horse racing Or playing base ball!

Come when he is sent for?
What else is he meant for!
But it's what you'll repent for
If you send without cause:
Being sorry
Will hardly
Appease him—so pause

Faith!—betimes he's clean cranky: Then (Moody and Sankey!) Better step aside, thanky.— But never drop out:— When he's wry, lads, Stand right by, lads.— I'ay his debt with a shoun!

For we know he's as tender.

A mother's defender.

When dark fears attend her.

Fighting death with his might—

Mother and man. sir.

They will answer

With a prayer for this knight.

Rough and brown as the heather: Fun, hardship, and weather All working together Have seasoned his age To the queerest And dearest Warm heart and sweet sage.

Big, sport loving, thrifty—
Queer, tender, and mifty—
Sentimental and fifty—
That's the way of him:—loud
Shake it out, then,
In a shout, men.—
Ev'ry throat in the crowd!

Herbert Wescott Fisher, of Nordhoff, Cal., in New Haven Register.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending November 25, 1908.

BRYAN, WM. M., Assistant Surgeon. Upon expiration of Present leave of absence, relieved from duty at the New Orleans Quarantine Station, and directed to proceed to the South Atlantic Quarantine and assume

command. BURKHALTER, J. T., Passed Assistant Surgeon. Upon being relieved by Surgeon W. P. McIntosh, directed to proceed to Gulf Quarantine Station and assume command.

CARRINGTON PAUL M., Surgeon. Upon being relieved by Passed Assistant Surgeon H. S. Mathewson, directed to proceed to San Diego, Cal., and assume charge of

COLLINS, G. L., Passed Assistant Surgeon. Granted three days' leave of absence, from November 17, 1908, under

paragraph 189, Service Regulations.
Goldsborough, B. W., Acting Assistant Surgeon. Granted six days' leave of absence from November 28, 1908, un-

der paragraph 210, Service Regulations.
GRUBBS, S. B., Passed Assistant Surgeon. Directed to report at the bureau for further instructions.

GUSTETTER, A. L., Acting Assistant Surgeon. Leave of absence for ten days, from November 15, 1908, granted November 9, 1908, amended to read from November 16, 1908.

N, M. K., Passed Assistant Surgeon. Upon being relieved by Assistant Surgeon William M. Bryan, directed to proceed to Baltimore, Md., and report to the Medical Officer in command for duty and assignment to quarters

HILL, EUGENE W., Acting Assistant Surgeon. Granted four days' leave of absence, from November 24, 1908, under paragraph 210, Service Regulations.

Holt, John M., Passed Assistant Surgeon. Granted one day's leave of absence.

day's leave of absence.

KALLOCH, P. C., Surgeon. Directed to proceed to Oak
Grove, Me., for special temporary duty.

LIGHT, S. D. W., Acting Assistant Surgeon. Granted twenty-two days' leave of absence, from November 17, 1908.

MATHEWSON, HENRY S., Passed Assistant Surgeon. Upon
being relieved by Passed Assistant Surgeon. C. W.
Wille, directed to proceed to Fort Stanton, N. Mex.,
and assume command. and assume command.

MINTHORN, HENRY J., Acting Assistant Surgeon. Granted seven days' leave of absence from November 23, 1908,

under paragraph 210, Service Regulations.

TAPPAN, J. W., Acting Assistant Surgeon. Directed to make inspections at Del Rio and Hidalgo, Tex.

THOMPSON, JOHN K., Pharmacist. Directed to proceed to Angel Island Quarantine and report to the Medical

Officer in command for temporary duty.

Wertenbaker, C. P., Surgeon, Detailed to represent the Service at the Thirteenth Annual Meeting of the Seaboard Medical Association of Virginia and North Caroboard Medical Association of Virginia and North Caroboard Medical Association of Virginia

lina at Washington, D. C., December 1 to 3, 1908.

WILLE, C. W., Passed Assistant Surgeon, Upon being relieved by Passed Assistant Surgeon J. T. Burkhalter, directed to proceed to Cleveland, Ohio, and assume

Appointment.

Dr. Carlisle P. Knight appointed an acting assistant surgeon for duty at Kobe, Japan.

Board Convened.

Board of medical officers convened to meet at the Marine Hospital in Baltimore, Md., November 25, 1908, for the purpose of conducting physical examinations of the members of the graduating class of cadets of the Revenue Cutter Service; Passed Assistant Surgeon W. C. Billings, chairman; Assistant Surgeon A. J. Warner, recorder.

Army Intelligence:

Official list of changes in the stations and duties of offi-, in the Mexical Courts of the United States,

Enders, W. J., First Lieutenant, Medical Reserve Corps.
Granted leave of absence for ten days.
KELLY, J. P., First Lieutenant, Medical Reserve Corps.
Relieved from duty at Fort Miley, Cal., and ordered to Oahn, H. T.

Kennedy, J. M., Major, Medical Corps. Ordered to report December 1, 1908, for duty as Chief Surgeon. Department of California.

MORSE, C. F., Captain, Medical Corps. Relieved from duty at Fort Howard, Md., and directed to proceed to Fort

Huachuca, Ariz., to accompany troops to the island of Oahu, H. T., for duty there.

SIEPHENSON, A. V., First Lieutenant, Medical Reserve Corps. Honorably discharged from the service of the United States.

TROTTER-TYLER, G., First Lieutenant, Medical Reserve Corps. Ordered from Fort Adams, R. I., to Fort Revere, Mass., for temporary duty.
WILLIAMS. A. W., Captain, Medical Corps. Granted leave of absence for three months.

The following first lieutenants of the Medical Reserve Corps have been ordered to active duty in the service of the United States: W. T. Councilman, Simon Flexner, Alexander Lambert, J. H. Musser, W. S. Thayer, V. C. Vaughan.

The following medical officers were appointed members of a board to meet at Washington, D. C., on December 7, 1908, to investigate the question of immunizing the regular 1908, to investigate the question of immunizing the regular, and, in case of war, the volunteer, army against typhoid fever: W. T. Councilman, First Lieutenant, Medical Reserve Corps; Simon Flexner, First Lieutenant, Medical Reserve Corps; J. H. Musser, First Lieutenant, Medical Reserve Corps; R. M. O'Reilly, Brigadier General, Medical Corps; Frederick F. Russell, Captain, Medical Corps; W. S. Thayer, First Lieutenant, Medical Reserve Corps; V. C., Vaughan, First Lieutenant, Medical Reserve Corps.

Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the week ending December 5, 1908:
CURTIS, E. E., Assistant Surgeon. Ordered to the Chatta-

nooga.

DESSEZ, P. T., Passed Assistant Surgeon. Detached from duty at the naval hospital, Mare Island, Cal., December 31, and ordered to the Pacific Fleet, sailing from San Francisco, Cal., about January 5.

Dunbar, A, W., Surgeon. Ordered to command the Re-

lief.

OLSON, C. M., Assistant Surgeon. Ordered to the Culgoa. SPEAR, R., Surgeon. Detached from the Relief and ordered to the Rhode Island.

Stokes, C. P., Surgeon. Detached from command of the Relief and ordered home.

Births, Marriages, and Beaths.

Married.

CLEMENTS—MALONE.—In Philadelphia, on Thursday, December 3d, Dr. Ralph L. Clements, of the United States Department of Agriculture and Miss Helen B. Malone. ROGERS—TARBELL.—In Garden City, L. I., on Monday, November 30th, Dr. Lester Brooks Rogers, of New York.

and Miss Louise Tarbell.

BACON.—In Riverside, Rhode Island, on Sunday, November 22nd, Dr. Walter A. Bacon, aged thirty-five years.
BUSHNELL—In East Orange, New Jersey, on Saturday,
November 28th, Dr. Hanley Nelson Bushnell, aged eighty-

EARHART.-In Philadelphia, on Friday, December 4th,

Dr. William J. Earhart, aged sixty-seven years.
Homer.—In Newburyport, Massachusetts on Tuesday,
November 24th, Dr. John Homer.
IRELAND.—In Cincinnati, Ohio, on Saturday, November
28th, Dr. John M. Ireland.

28th, Dr. John M. Ireland.
JENNINGS.—In Brooklyn, on Monday, November 30th,
Dr. Ella A. Jennings.
KNAPP.—In Hackensack, New Jersey, on Thursday, December 3d, Dr. Louis P. Knapp.
McCosu.—In New York, on Wednesday, December 2nd.
Dr. Andrew J. McCosh, aged fifty years.
STELLE.—In Campton, Kentucky, on Thursday, November 26th, Dr. Wiley Steele.
WILELER.—In Chatham, New York, on Thursday, December 3d, Dr. John T. Wheeler, aged fifty-eight years.
WINTELS.—In Hickman, Kentucky, on Wednesday, November 25th, Dr. Will Winters, aged fifty-five years.

TREATMENT OF BILIARY DISEASE AS DETER-MINED AT THE OPERATION.

> By Howard Lilienthal, M. D., New York.

The surprises of abdominal section occur most frequently in one's early days of surgery. Later we learn not to be surprised at any condition within the peritoneal cavity, however interesting or unusual it may be. If experience in this branch of our art teaches anything, it teaches that the most logical and scientific diagnosis may be completely upset at the first stroke of the knife through the peritonæum. Cancer of the liver becomes common duct stone and vice versa. An enlarged Riedel's lobe turns out to be the kidney; carcinoma of the pylorus may have been simulated by pericholecystitis, and so on, in an endless catalogue. With riper knowledge the typical cases become more rare, and the beautiful confidence and accuracy of youth vanish, but there comes a quiet and safe uncertainty which promises well for the patient on the operating table. Instead of the unexpected shock of an overturned diagnosis, with its doubt as to the propriety of the next step, we have a cool and instant acceptance of conditions as they are encountered, and the work goes on with little or no delay incident to the change in plan. It is certainly wise not to be too sure of what will be done at an operation, and frequently embarrassment may arise from preoperative promises made to the patient or his friends as to the exact nature of the contemplated procedure. It is better not to operate unless there is full permission to do anything or everything which may be necessary for the welfare of the patient. Serious legal complications have occasionally arisen, to the annovance and anxiety of the surgeon, whose professional conscientiousness was greater than his worldly wisdom. Always try to have the family physician present at the operation, not only as a matter of courtesy, but for self protection and to share responsibility. No matter how much confidence the patient may have, the surgeon is usually a comparative stranger, and motives are sometimes questioned by the suspicious.

Before performing a laparotomy every reasonable method of investigation should be practised and a working diagnosis should, in any event, be arrived at; but all, even remote possibilities, must be considered, so that, as in a well played game of chess, the countermove for every play of the adversary is known in advance.

In diseases of the biliary system all the usual examinations should be made, and in the more chronic ailments analysis of the stomach contents must not be omitted. Many cases diagnosticated as disease of the gallbladder are in reality gastric, duodenal, or even renal. Again, there may be clear and convincing proof of gallbladder disease, when at the time of exposure the viscus may be found apparently normal. Even a "normal" gallbladder, in the absence of gastric, duodenal, or renal disease, had better be removed, if the symptoms are sufficiently grave to warrant an operation and the exploration is otherwise negative.

CASE I.—Mrs. K. twentveight years old, had reneated attacks of typical biliary colic with no history of jaundice. She was first seen by me in consultation with Dr. L. Stieglitz during an attack of what looked like cholecystitis complicating a severe influenza. There was complete recovery, but other colicky attacks followed and on the evidence presented an operation was decided upon. I expected to find a single large calculus or a few large calculi of such size that passage through the cystic duct would be impossible, this accounting for the absence of jaundice. To my surprise the gallbladder on exposure was almost normal in appearance and certainly contained no stones. Cholecystostomy promised little or nothing, so with the concurrence of her physician the gallbladder was removed. It was noted then that the lumen of the cystic duct was so contracted that it admitted only the finest probe. Evidently there had been at some time ulceration and cicatrization with stenosis. Recovery was quick and seems to be permanent.

It sometimes happens that one makes a diagnosis of disease of the gallbladder and at operation there is difficulty in even finding the organ. Here the sense of touch as well as that of sight will sometimes aid us.

Case II.—A. K., a man, aged fifty-four, patient of Dr. deure, had obstructive jaundice and glycosuria, the attack during which I had seen him, March 17, 1904, having begun about a week before. There was also an old history of trouble dating back six years. He was deeply jaundiced and there was vomiting but no fever. Four or five days later, after repeated calomel purging there was sudden relief of pain, but the jaundice increased. I operated upon him at Mt. Sinai Hospital. Opening the right upper quadrant between the fibres of the rectus muscle, no gallbladder could be seen, but the palpating finger discovered a hard mass in the substance of the liver near the fissure. It proved to be the gallbladder, contracted and completely buried in liver substance; its walls were thick and gristly. In spite of the jaundice and glycosuria this gallbladder was removed by actually digging it out of its hepatic bed. The common duct was opened, a stone extracted, and the wound sutured without drainage of the duct. Smooth convalescence followed.

These thick walled, chronically inflamed gall-bladders are extremely apt to become carcinomatous, and should, therefore, be removed.

In the presence of pericholecystitis with suppuration it may be unwise to make the necessary dissection for the removal of a gallbladder even though

its walls are thickened and the other indications for cholecystectomy are present. Much dissection and handling in the neighborhood of a recently evacuated abscess is unsafe, and relief should be our aim, postponing the radical procedure until a more fitting time. A case in which there was a most unusual complication will illustrate the point.

Case III.—Rudolph G., twenty-eight years oid, had suffered for years with "indigestion," the attacks lasting for several days. There had never been jaundice. There was several days. There had never been jaundice. There was pain in the pit of the stomach, the right hypochondrium, and back. No chills and only moderate fever. He came to my office on November 24, 1907, and on examination I could easily make out a hard, tender mass close to the abdominal parietes in the right hypochondriac region. Periodelegistic with chelekithics, who disconstituted and cholecystitis with cholelithiasis was diagnosticated and operation advised. Soon after he entered the hospital, and on section an abscess about the very much thickened gallbladder was evacuated, a single large spheroidal stone was removed from the viscus itself, and the two cavities were drained separately. The discharge of pus was rather profuse, the odor being very foul; the patient, however, did not appear to be absorbing much toxine, for he was not in a septic condition. One day about three weeks after the operation, a bladderlike mass the size of a white grape was washed from the wound, and it was evident that we were dealing with the unusual complication of a hydatid cyst in the presence of gallstone disease. For a number of weeks the discharge continued, large numbers of hydatids being cast off. Finally a counteropening was made in the back for drainage, and a double handful of calcareous cyst wall was removed. Perfect recovery followed.

I am quite certain that had I attempted to remove this gallbladder at the primary operation, serious infection and

great danger to the patient would have resulted. Should this man ever again be troubled by symptoms referable to the gallbladder, it would be justifiable to remove the of-

fending organ.

There is one rule which is as inflexible as any in surgery, and that is that when icterus is present the operation should not be stopped until bile flows. But, naturally, the mere appearance of bile may not mean that we have done all that should be done. Bile may freely run from an incision in the gallbladder or the ducts above an obstruction, and this obstruction must be overcome to accomplish a radical cure. If this cannot be safely done at one sitting we may rest satisfied with the drainage and postpone clearing the ducts. When there is deep icterus with great hepatic engorgement and slow blood coagulation, we must do the work through the smallest possible incision with the least possible handling of the viscera. Then in a few weeks we may operate for the actual cure of the disease. It is much the same in biliary obstruction as in intestinal obstruction-better not attempt too much at a time, but rest content with the procedure involving the least element of risk. When the patient has recovered his strength he will be better able to stand the shock of the more serious operation. It is a good principle rather to multiply small operations than unnecessarily jeopardize the patient by a single grave one, and this often in spite of the wishes of the patient or his friends, who may be anxious to have the disagreeable experience over.

When, however, there is a distended gallbladder with sepsis, with or without icterus, the gallbladder may be emptied or removed, and the entire operation concluded without show of bile, provided the patient is too weak to permit persistent dissection. The obstruction is caused by the swelling of the mucosa of the cystic duct. In a few days, when the engorgement has subsided, the bile will flow

freely.

Case IV .- I. G., a man of about fifty, alcoholic, had never to his knowledge suffered from bilary disease. I saw him with his physician, Dr. Spivacke, after about a week's illness with jaundice, high fever, abdominal distension, and an enormously increased liver dulness. Through the unwillingness of the patient to submit to operation, the case dragged on for several days, all the symptoms becoming aggravated, and the pulse finally becoming so wretched, and the patient's general condition so critical, that when consent was obtained I was afraid to do more than a quick cholecystostomy with local anæsthesia. The gallbladder, full of pus and stones, was drained, not a trace of bile appearing for several days afterward. Finally matters took a pearing for several days afterward. Finally matters took a turn for the better, the jaundice yielded to a profuse biliary discharge from the wound, and for a number of weeks the patient continued to improve. The enlarged liver became much smaller, but the biliary fistula refused to heal, and the stools remained clay colored. At the subsequent operation the gallbladder was removed, a stone was taken from the common duct, and the patient made a good recovery.

In the aged and in the extremely feeble do as little as will suffice to overcome the present emergency, and gauge your operation with a view to getting the patient out of bed as early as possible.

Never, except in the presence of collapse, close the abdomen without examining the pylorus and the pancreas. If white or vellow plagues of fat necrosis are seen in the omentum or mesentery it means that the bile passages should be drained, preferably by cholecystostomy, whether stones are present or not. The fat necrosis indicates the presence of acute pancreatitis, a diagnosis which is very rarely made before operation.

In conclusion a few words about the technique: First: Use but little gauze packing, even of the temporary variety. Many operators are absurdly afraid of soiling the peritonæum with a few drops of bile or pus. Infection, perhaps dangerous, may follow the soiling of the handled and damaged peritonæum, but the mere presence of bile or even pus will not cause general septic peritonitis unless the integrity of the peritonæum has been impaired by rough handling or contact with gauze. Another reason for avoiding packings is that they tend to produce adhesions, which may not only be embarrassing should a secondary operation be necessary, but which may in themselves give rise to complete or incomplete obstruction, particularly in the neighborhood of the pylorus.

Second: In case of common duct disease this structure is more easily reached and manipulated when the gallbladder has been removed and the cystic duct drawn up by traction sutures. stump of the gallbladder having been secured, it is not usually difficult to slit the duct with scissors down into the common duct. Hæmorrhage may be accurately checked and the work can go on in a

quiet and orderly manner under the eye.

Third: Leave the traction sutures in place. It may be that in spite of every precaution recurrent bleeding occurs. I have seen a life lost in the blind groping for points of hæmorrhage at the bottom of a well of blood. If the traction sutures are in place it is but the work of a few seconds to reopen the wound and draw into view the parts where the trouble is most frequently found.

As in all surgical work, the personal element of the operator is a most vital one. Minute points of technique, difficult or even impossible to describe, may perhaps count heavily when it comes to figuring percentages. Among other things, I am convinced that speed without haste is of the greatest

importance—and speed is best attained by knowing what is to be done and then doing it with little waste of useless effort. We all know how much time is saved in travelling over a well known road where one need not consult maps or ask the way. All the more is it so with work in surgery. probabilities are that the twentieth operation of a given type will "go" more rapidly and smoothly than the first or even the tenth. The neatest, the quickest, and the safest work-other things being equal-will be done by the man who has had the greatest amount of intelligent and profitable experience.

115 EAST SEVENTY-THIRD STREET.

THE MISTLETOE.

(Viscum album, "All-heale"); A Monster in Botany; a Dryad in Mythology; a Panacea in Therapeutics; a Perennial Yuletide Symbol of Seminal Survival and Reproductive Vitality.

By JOHN KNOTT, A. M., M. D., Ch. B., and D. P. H. (Univ. Dub.); M. R. C. P. I.; M. R. I. A.; etc., Dublin, Ireland.

The vegetable items of the overcrowded materia medica of the successive ages of human existence, as chronicled in the history of the same, have individually had allotted to them their special geographical and seasonal areas and periods of adaptability and usefulness. Many of the representative leaders of the medical schools of the older (prescientific) centuries believed, or professed to believe, that every locality in the world brought forth plants of which the tissues and juices contained the remedies requisite for the healing of its characteristic diseases. And the powers of a merciful Providence -- as represented and applied by the omnipresent influence of invisible and mysterious Nature-did not firmly bolt the Doors of Knowledge against the earnestly curious inquirer. The available clue-the "open sesame"-to a knowledge of every therapeutic item of the vegetable kingdom was furnished by the signature of the vegetable species in each case; the formative stamp which furnished the collective external testimony to its inward qualities and powers, which pretty exactly corresponded to that furnished by the physiognomy of the members of the animal kingdom-including that of the theomorphic entity, homo sapiens. Some of the curative agents, so revealed, were discovered by experience to have powers of very limited range and disappointing quality; others retained their reputation through very many succeeding generations-some even down to our own; others still retained some of their popularity as symbols, or items of scientific (or æsthetic) interest, long after their therapeutic reputation had almost wholly faded.

Even in our own provokingly practical, and materialistically mechanical generation, the annual arrival of the festive season of Christmastide does not fail to carry with it, in the usual course of events, a renewal of old acquaintances and a repolishing up of old friendships-concurrent with the dutiful celebration of certain household, and other correlated, customary rites. The advene of the brumal solstice will. I would fain hope, never fail-throughout our unromantic twentieth century, or even its remotest successors-to reburnish some of the fireside associations of the antique cult of the Lares and Penates. The Yuletide log on the kitchen hearth, and the Christmas tree on the drawing room floor, always offer, and must evermore recall, the brightest associations in the memories of hearts still unsullied, and affections still vivid and loyal; while to the members of our social community who are about to enter on the trying race for life there is probably no emblem of this sacred season that will be found to elicit more thrilling sensations than will the mistletoe. A strange entity of the vegetable kingdom is, indeed, the genus Viscum, of which this our osculatory Viscum album appears to be the only one of the eighty species duly described and named that has made itself a home on European soil. And the curious vagaries of its life history never failed to prove a puzzle to the apostles and pioneers of botanical science and exploration—fairly comparable, indeed, to those elusive riddles which were placed in the pathway of the curious in bird lore by the domestic idiosyncrasies of the cuckoo, the peculiarly unmigratory flights of the corncrake, and the tropical (and submarine) vacations of the swallow. And the sceptical eye still continues to recognize the existence of a somewhat corresponding haziness-investing, even in our own day, in the "scientific" items of natural history which occupy the position of orthodox and accepted biological gospel in the case of each one of those several stumbling blocks of the respective pathways of the botanist and the ornithologist.

The almost weird attraction which the unique individuality of this member of the vegetable kingdom has secured for itself in the folklore, as well as in the botanical—and even medical—literature of so many countries, throughout a period of over two thousand years (at the least), furnishes some tempting food for reflection to the philosopher as well as to the scientist. The writings of Theophrastus and of the elder Pliny prove that even long before the dawn of the Christian era the Viscum album was not only an object of curious and wondering inquiry to the botanical specialist, and a practical agent of special functional importance in the hands of the speculative bird catcher, but a highly accredited item of the therapeutic armamentarium, and an object of the most devout attention to the priesthood of Celtic Druidism and their unnumbered disciples and followers. In such respects it rivalled the lotos of the ancient Egyptian, and the more remote "celestial," empires; its continental prominence far overtopped the relatively local eminence accorded, in later times, to the Swiss Edelweiss, and our own Irish shamrock, respectively. In his encyclopædic compilation of the facts and fables (and art, and science, and gossip, and theory) of the natural history obtainable from the literature and the folklore of the nations of classic antiquity, Caius Plinius Secundus informs his readers, just as ivy in time destroys the vitality of the trees to which it clings for support: "The like is to bee said (in some sort) of the Misselto, although it is generally thought, that the harme thereby is not so soon seen." (Philemon Holland's version.) And he then proceeds to observe:

And this you must thinke, that this Misselto is not to be taken for the fruit of a tree, and therfore as great a

wonder it is in nature, as any other: for some things there be, that not willing to grow out of the earth, engender in trees, and having no proper place of their own habitation to seat themselues in, sojourn as it were and make their abode with others, and of this nature is the Misselto.

Then after enumeration of the names and respective habitats of the more prominently recognizable of known parasitic plants, the grand old natural annalist goes on to say (in the quaint rendering of his medical "Translator-General"):

But to return againe to Misselto, there bee three kinds tree is called Stelis in Eubea, and Hyphear in Arcadia. And as for that which properly is Misselto indeed, most men are of opinion, that it groweth fast to the common Oke, the wild Robur, the Holme, wild Plumtree, and the Terebinth, and lightly on any other trees. Howbeit in greatest plenty it is seen yoon the Oke, and that is named Dryos Hyphear. A difference there is in the Hyphear and Misselto, on what tree soeuer they are found (except the Holm and common Oke) in regard of the sauor, which is strong and stinking in the one more than the other. The leafe of both of them have no pleasant smell, and in the Misselto it is bitter, clammy, and viscous besides. There is moreouer, by mens saying, another difference in Misselto: for that which groweth vpon trees, shedding their leaues in winter, loseth also his owne leaues; but contrariwise, it continueth alwaies green vpon such trees as hold their leaues all the yeare long. Moreouer, set or sow this Misselto what way soeuer you will it will neuer take and grow: it comes onely by the mewting of birds, especially of the Stockedoue or Quoist, and the Black bird, which feed thereupon, and let it passe through their body. And this is the nature of it, vulesse it be mortified, altred and digested in the stomacke and belly of birds, it will neuer grow. It exceedeth not al any time a cubit in heighth, notwithstanding it be alwaies greene and full of branches. The male beareth a certaine graine or berry: the female is barren and fruitlesse. But sometimes neither the one nor the other beareth at all.

The uncanny awe and theological dignity with which the mistletoe was invested by the Druidical mythology of western Europe in the olden time are very difficult to realize in our own practical and mechanical and calculating-and jaded and worriedtwentieth century. They account, of course, for the wondrous medicinal virtues attributed to this strange plant by the members of the august hierarchy of that religion. The devotion-both theologic and therapeutic-which was so universally accorded to the mistletoe in that quaint and curious cult, which governed the higher emotions of the inhabitants of western Europe before the dawn of Christian enlightenment, has been sketched by Pliny in considerably full detail. It is thus reproduced in the delightful version of Philemon Holland, Doctor of Physicke:

And forasmuch as we are entered into discourse as touching Messelto, I cannot ouerpasse one strange thing thereof veed in Frence: The Druidæ (for so they call their Diuinors, Wisemen, & the state of their Clergy) esteeme nothing more sacred in the world than Misselto, and the tree whereupon it breeds, so it be on Oke. Now this you must take by the way. These priests or Clergy men chose of purpose such groues for their diuine seruice, as stood only vpon Okes; nay, they solemnise no sacrifice, nor perform any sacred ceremonies without branches & leaues thereof, so as they may seem well enough to be named thereupon Dryide in Greek, which significath as much as the Oke priests. Certes, to say a truth, whatsoeuer they find growing vpon that tree oner and besides the own fruit, be it Misselto or any thing else, they esteem it as a gift sent from heauen, and a sure sign by which that very god whom they serue glueth them to vuderstand, that he hath chosen that peculiar tree. And no maruel, for in very deed Misselto is passing geason and hard to be found vpon the oke; but when they meet with it, they gather it very denoutly

and their seuerall ages, which haue their revolutions every thirty yeres) because she is thought then to be of great power and force sufficient, and is not yet come to her halfe light and the end of her first quarter. They call it in their language All-Heale, (for they haue an opinion of it, that it cureth all maladies whatsoeuer) and when they are about to gather it, after they haue well & duly prepared their sacrifices and festival cheere vuder the said tree, they bring thirther two yong bullocks milk white, such as neuer drew in yoke at plough or wain, and whose heads were then and not before bound by the horn: which done, the priest araied in a surplesse or white vesture, climbeth vp into the tree, and with a golden hooke or bill cutteth it off, and they beneath receive it in a white soldiers cassock or coat of armes: then they fall to kil the beasts aforesaid for sacrifice, numbling many oraisons & praying deuoutly: that it would please God to blesse this gift of his to the good and benefit of all those to whom he had vouchsafed to give it. Now this persuasion they haue of Misselto thus gathered, That what living creatures soeuer (otherwise barren) do drink of it, will presently become fruitfull thereupon: also, that it is a soueraign countrepoison or singular remedie against all vernine. So vain and superstitious are many notions in the world, and oftentimes in such frivolous and foolish things as these.

The very tone in which the contents of the above summary is conveyed constitutes demonstrative evidence of the prominence of the position occupied by this erratic denizen of the vegetable kingdom "in the public eye" of western Europe in those centuries of pagan antiquity. Which is further emphasized by the very careful details to which he treats the reader. And the fact that it is extremely rare to find it atached to the oak ("il est extrêmement rare de le recontrer sur les chênes, et jusque" à présent on ne cite guère en France que douze ou quinze localités ou son parasitisme sur les arbres ait été constaté d'une façon certaine," in the words of the eminent botanist, Lefevre) must have conferred a special value on such specimens.

The sacred veneration which was thus accorded to the mistletoe would seem to have been a specially characteristic feature of the old Gallic version of nature worship, and very much "to the manner born" in that sunny land of evermore uneasy faith. In the learned and interesting folio of *The Antiquities of Cornwall* (Oxford, 1754) Borlase discusses the ceremonial details recorded by Pliny (as reproduced before), and gives a special quotation (from "Keysler, 305") in proof of the fact "that the footsteps of this custom still remain in some parts of France":

In Aquitania quotannis Prid. Kal. Jan. pueri atque adolescentes vicos villasque obeunt carmine stipem petentes sibi atque aliis pro voto in exordio novi anni acclamantes, Allguy, L'an neuf.

A very significant and very impressive item of testimony to the pride of place occupied by the mistletoe in the religious mind of cultured classical antiquity is also presented by the similitude to the "golden bough" of the Sibyl, as depicted by "the divine Maro" in his unique sketch of the pagan "mysteries":

Quale solet sylvis brumali frigore viscum Fronde virere nova, quod non sua seminat arbos, Et croco fœtu teretes circumdare truncos: Talis erat species auri frondentis opaca

Ilice: sic leni crepitabat bractea vento.

Æncidos, vi., 205, et seq.

And the striking macroscopic appearances which arrested the attention of the nature worshipers of classical antiquity had their counterpart in the revelation of modern microscopic observation. Thus we learn from one of the most accomplished botanists of the

last quarter of the nineteenth century; "Ce sont certaines cellules appartenant directement à vassise sous-épidermique de la face ventrale des carpelles soudés qui produisent, suivant la règle ordinaire, chacune un sac embryonnaire. Ces sacs embryonnaires sont variables en nombre et en position; un seul, parfois deux ou trois d'entre eux, arrivent à se développer complètement. Ainsi, de même que les sacs polliniques sont plongés dans le parenchyme des sépales, de même les sacs embryonnaires sont immerges dans le parenchyme des carpelles. Par là les Guis offrent l'exemple de la plus grande réduction possible de l'appareil sexuel chez les Phanérogames" (Van Tieghem, 1884). And how the germinal grain is transported and deposited in the seat of its future growth is a question which, if the truth be clearly confessed, has not even yet been finally solved-the riddle still awaits the arrival of its Œdipus!

Another factor in the genesis of the popular fame of the mistletoe was contributed by the fact that its fruit has, from time immemorial, been utilized for the preparation of birdlime. This process is also described in considerable detail by Pliny, whose account of the same was thus "Englished" by the in-

defatigable Philemon Holland:

Now as touching Birdlime, it is made of the berries of is tisseltoe, gathered in haruest time before they are ripe; for if they should tarry still to take shownes of ram, we might they thrine and increase in bignesse, but their strength and vertue would be gon clean, for euer making any such glew, or birdlime aforesaid. Being so gathered, as is beforesaid, they must be laid abroad a let to putrifie for the space of 12 daies or thereabout. This one thing yet in the whole world is the better for putrefaction, and serueth to good purpose. When this is done the said beries thus putrified and corrupt, are beaten or punned once again with mallets, in running water; by which means when they are husked and turned out of their skins, the fleshy substance within, becommeth glutinous, and will stick too, in a manner of glew. This is the way to make birdlime for to catch poore birds by their wings, entangled therewith; which foulers vse to temper and incorporate with the oile of Walnuts, when they list to set limetwigs to take foule.

Further researches into the mythologies of later dates and of remoter regions have shown that the religious veneration for the mysterious mistletoe was cultivated by other priesthoods and by tribes and nations of far different theological doctrines. The lore of this unique plant has been accorded a prominent place in the Volüspa and other Scandinavian Sagas. It was with a mistletoe branch-or an arrow therefrom prepared-that the blind and heavy headed deity Hodur aimed his deadly blow at Balder, the god of light (or benevolent principle) of northern mythology. The story is, indeed, one of the most characteristic of the whole Scandinavian system of symbolism and allegory. learn therefrom that twin sons of diametrically opposite spiritual characters and physical qualities were born to Odin and Frigga. They represented very exactly, indeed, a northern edition of the Zoroastrian conception of Ormuzd and Ahriman. Balder, the beautiful and lovable, was worshiped as the pure, and stainless, and radiant deity of light and innocence and health; while Hodur, god of darkness, was blind as the obscurity of evil and sin which he symbolized—sombre and taciturn, as denoting the gloom of the chamber of sickness, and

the silence of present sorrow and approach of impending death. From the dazzling snowy brow of the former appeared to radiate the beams of refreshing sunshine which gladdened the hearts of all beholders—both divine and human, and the source thereof was specifically indicated by the golden locks which were arranged with such asthetic perfection.

Of all the twelve 'round Odin's throne. Balder, the beautiful, alone, The sun god, good, and pure, and bright, Was loved by all, as all love light.

—Valhalla (I. C. Jones).

As might be anticipated, the infant sun god reached fully grown maturity with marvelous rapidity, and was soon admitted to membership of the Council of the Gods. He made the palace of Breidablik his domestic mansion, in which he lived in absolutely perfect conjugal bliss with his adorable young bride, Nanna (blossom), who was the daughter of the beautiful and lovable goddess Nip (bud). The silver dome of this unique mansion was supported by golden pillars; and the hygienic purity of its precincts was maintained in a degree of perfection so spotless that nothing common or unclean was ever admitted to stain any part of its hallowed precincts. And the only item of knowledge which was hidden from the radiant eyes of its tenant was the divination of his own ultimate des-The mystical runic lore was perfectly familiar to him, and the runic characters were graven on his tongue. As the god of healing, he was thoroughly versed in the virtues of simples; and one of these, the camonile, was popularly known as "Balder's brow," for its flower was distinguished by a brightness and purity corresponding to those of the brow of that deity. According to the metrical account of Matthew Arnold (Balder Dead):

. . His own house
Breidablik, on whose columns Balder graved
The enchantments that recall the dead to life.
For wise he was, and many curious arts,
Postures of runes, and healing herbs he knew;
Unhappy! but that art he did not know,
To keep his own life safe, and see the sun.

And as time passed, as change for the worse was observed in his aspect and demeanor; so that the other gods who all loved him so dearly, and who had been accustomed to see him always so radiant and happy, were greatly troubled on seeing the same. His motions became heavy and sluggish, his step lost its peculiar elasticity, a look of careworn gloom came permanently to overspread his face, and the light which used to diffuse joy and gladness all around him faded from his eyes of glorious blue. His parents were, of course, the most distressed of all by the melancholy change in their beloved son. But it was only after they had implored him long and tenderly that he communicated the secret cause of his grief. In the words of the Lay of Vegtam (Thorpe's translation):

To that god his slumber was most affecting; His auspicious dreams seemed departed.

—and so his slumbers, which had formerly been a reservoir of refreshing peacefulness and restfulness, had become a source of corroding care; as he was ever troubled by dark and oppressive dreams, the gloom of which was intensified during waking

hours by the fact that he could not recall their substance. His anxious parents became oppressed by gloomy forebodings, and took such precautionary measures as seemed advisable. Accordingly, Frigga dispatched her messengers in all directions, with plenary powers and instructions, and with the strictest charges to take no rest till they elicited a solemn vow from every creature—animal, vegetable, and mineral—that it should in no way harm Balder. As the radiant god of light was specially beloved of every creature in the universe, the requisite oath was taken by every member of creation—one only having been omitted, as a puny, trivial, inoffensive thing which could cause no harm to anything. As Sæmund's Edda (Thorpe's version) tells the story:

On a course they resolved; That they would send To every being, Assurance to solicit, Balder not to harm. All species swore Oaths to spare him; Frigga received all Their yows and compacts.

And, accordingly, the goddess-mother Frigga was thus enable to resume her spinning in great contentment of mind; as she now felt assured that no harm could possibly come to her most favored

child.

But the father of the northern sun god had in the meantime been also busy, and his anxiety took the shape of an effort to obtain and utilize supernatural knowledge. So he determined to consult one of the deceased Vala or prophetesses. this object he performed the pilgrimage which offers another of the object lessons which go to demonstrate the unity of the emotional viewpoint of humanity, in every age and locality of its recorded existence. How both extremes of the European Continent meet on this plane will be apparent to the thinking reader who has familiarized himself with the visions of Homer, and Virgil-with that of their mediæval successor Dante, and of their northern rivals in visionary inspiration. And the Sybil of Scandinavian creation was located in cosmic space, and approached by the divine (and paternally anxious) Odin in a way which suggests a blending of the theories of the poets just named with the practice of the gloomy and almost desperate King of Israel when he elected to avail himself of the powers of the witch of Endor. For he mounted his eight footed steed Steipnir, and rode across the tremulous bridge Bifrost; whence he passed along the weary road that leads to Giallar and the entrance of Niff-heim. There after passing through Helgate, and escaping the guardian dog Garm, he penetrated to the gloomy mansion of Hel, the monarch of the Scandinavian kingdom of the departed. As versified by Thomas Gray (Descent of Odin):

Uprove the king of men with speed And saddled straight his coal black steed; Down the yawning steep he rode, That leads to Hela's drear abode.

Here the divine visitor found that the Plutonic domain was richly furnished with the appurtenances of a luxury which gave him even more surprise than pleasure to observe. The couches were

richly decorated with tapestry and gold as if some specially distinguished guest were expected. The divine pilgrim was too anxious to wait to make casual inquiries, and hurried to the resting place of Vala, which had remained undisturbed for many years. Having reached it, he chanted the appropriate incantation, and traced the runic characters of which the power must be utilized in raising of the dead. As Gray continues to tell the story:

Thrice pronounc'd, in accents dread, The thrilling verse that wakes the dead: Till from out the hollow ground Slowly breath'd a sullen sound.

As usual with subterranean spirits thus called forth, the prophetess in question drew herself upwards with effective slowness of ascensional movement, and proceeded to inquire who it was that had so dared to interrupt her long repose. Odin did not feel disposed to reveal his divine identity in that very shady locality, and gave the name of Vegtam, son of Valtam, whose object was to ascertain for whom Hel was spreading her couches and preparing an elaborate feast. His worst fears were confirmed by being told in sepulchral tones that the expected guest was Balder, who was destined to be slain by his blind brother Hodur, god of darkness. Odin pressed the prophetess to reveal the name of the avenger of the murdered god-who was to have the privilege of carrying out a duty so sacred in the estimation of the Scandinavian races. He was then told that Rinda, the earth goddess, would bear a son to Odin, whose name should be Vali, and that the same would neither wash his face nor comb his hair till he had avenged the death of Balder. In the poetical version of the author last quoted:

In the caverns of the West, By Odin's fierce embrace comprest, A wondrous boy shall Rinda bear, Who ne'er shall comb his raven hair, Nor wash his visage in the stream, Nor see the sun's departing beam, Till he on Hoder's corse shall smile Flaming on the fun'ral pile.

The continued curiosity of Odin betrayed his divine identity, for when being asked "Who would refuse to weep at Balder's death?" the prophetess recognized at once that the querist was possessed of knowledge not vouchsafed to mortals. So that she at once sank back into the silence of the tomb—from which no incantation can allure her before the final crack of doom:

Hie thee hence, and boast at home, That never shall inquirer come To break my iron sleep again, Fill Lok has burst his tenfold chain; Never till substantial Night Hath reassum'd her ancient right: Till wrapt in flames, in ruin hurl'd, Sinks the fabric of the world.

With a mind depressed by the knowledge so acquired of the inexorable decree of Orlog (fate) regarding his best beloved son, Odin remounted his octopedal steed and returned, slowly and sadly to Asgard, where, on entering Glads-heim, he was somewhat restored to hopeful anticipation by hearing from Frigga that all the factors of cosmic space had promised not to harm Balder. But the gods exhilarated by knowledge of the same fact came to celebrate their "Olympic" pastimes in their

playground of Idavold, on the green plain of Ida. So effervescent was their joy at the assurance of the safety of their special favorite that they adopted a novel pastime, which was suggested by the same. They made Balder himself the target for every missile procurable, and their hilarity rose to the verge of frenzy when they found that nothing could hurt him. The uproar of laughter reached Frigga at her spinning wheel, who asked an old woman who happened to pass by the door what it was that had provoked the unprecedented outburst of divine hilarity. The reason was told by the wayfarer, who was no other than Loki in disguise; the personification of fire, who jealously hated Balder for the universal love which he inspired, and the brightness which always eclipsed his own. The goddess mother complacently mentioned the cause of Balder's safety, and the malignant Loki ascertained on closer inquiry that the mistletoe of the oak near Valhalla's gate was the sole cosmic item which had not entered into the covenant. The information gladdened the heart of the divinity of mischief, and he proceeded to utilize it the moment he had got beyond the range of Frigga's vision. He resumed his wonted form, and lost not a moment in finding the mistletoe in question, to which he was able by magic art to give unnatural size and hardness, so as to qualify it for the fashioning of a formidable arrow. When he returned to Idavold he found the blind Hodur leaning mournfully against a tree, being unable to take part in the general amusement, and having asked for the cause of his melancholy, and stimulated him by an insinuation that only a proud indifference could hold him so completely aloof from the universal amusement, he led the sightless deity into the midst of the arena, placed the mistletoe shaft in his hand, and indicated the direction in which it should be launched. A shuddering howl of terror and dismay greeted the ears of the blind and deluded deity, as Balder the beautiful fell to earth, mortally wounded by the fatal mistletoe. Thus versified by Matthew Arnold:

So on the floor lay Balder dead; and round Lay thickly strewn swords, axes, darts and spears, Which all the gods in sport had idly thrown At Balder, whom no weapon pierced or clove; But in his breast stood fixed the fatal bough Of mistetoe, which Lok, the accuser, gave To Hoder, and unwitting Hoder threw—'Gainst that alone had Balder's life no charm.

And thus was the evergreen vegetable parasite permanently associated in the Scandinavian mind with the temporary conquest of the principle of light and life by that of darkness and death! It was, accordingly, meet that it should be well in evidence at the seasonal descent into the adops of the brumal solstice.

It is of interest in this connection to note that the general opinion of the ancient herbalists, regarding the more usual deposition of the seeds of the mistletoe by the thrush, was so prevalent as to give origin to the classic proverb, which was popularly familiar in the days of Theophrastus and of Pliny: turdus sibi exitium cacat—an allusion to the fact that the thrush and blackbird were frequently caught by bird-lime. We find this proverbial phrase, indeed, recurring again and again, wherever allusions to the

mistletoe and its ways are much in evidence. And we may add that in presence of such universal recognition of the agency of healthy birds as carriers or "halfway houses" in the life pilgrimage of this our *Viscum album*, the "vulgar error," above referred to, of the widespread popular belief in the poisonous properties of the berries appears curiously inexplicable. But even the most advanced modern botany cannot truly claim to have plucked out the heart of the mystery of the germination of this curious vegetable. Boisduval tried to improve on the old classical version by announcing that the birds deposited the seeds on the branches of trees by a process of genuine vomiting! Gay and Durieu de Maissonneuve have advanced an ingenious theory -which has also been advocated by Lefèvre: "Les oiseaux, après avoir saisi les baies et en avoir avalé la pulpe, cherchent, en frottant leur bec contre les branches des arbres, à se débarrasser des graines ainsi que de la substance visqueuse qui y restent attachées: d'où résulte la fixation d'un grand nombre de graines à la surface des rameaux." The mistletoe, abounding as it does in France, has received special attention from the agriculturists as well as the botanists of that country. The botanical authority last named tells us that, however deposited, the mistletoe seed (graine du Gui) "présente cette particularité remarquable que la radicule, au lieu d'être dirigée par la pesanteur suivant la verticale, n'est sensible qu' à la lumiere; elle s'enfonce dans la branche, dequelque côte que la graine y ait été deposée, et toujours du côté le moins éclairé."

The same authority tells us that the farmers of the Vosges attach great value to the mistletoe of Abies excelsa and A. pectinata, in the fattening of their cattle and pigs. He also states that in other parts of France the mistletoe is given to cows for the purpose of increasing the production of milk.

There can be no doubt the very peculiar appearance and life-history of this remarkable plant were quite remarkable enough to secure for it the curious attention of the learned, as well as of the illiterate. in the prescientific ages throughout which imagination held the reins of thought. Its garb of persistent green presents a striking appearance amid the wintry nakedness of the surrounding forest trees. and the ripening of its juicy berries at a season in which all exuberant sap of the other members of the vegetable kingdom appears to have retreated to mother earth would account for a suggestion of supernatural generative agency. Even that great and worthy pioneer of modern English botany, the quaint John Gerrard, although he mentions the agency so often assigned to the thrush in the genesis of this vegetable parasite, gives precedence to the account that "this excrescence hath not any root. neither doth encrease himselfe of his seed, as some haue supposed; but it rather commeth of a certaine moisture and substance gathered together vpon the boughes and ioints of the trees, through the barke whereof this vaporous moisture proceeding bring-eth forth the Misseltoe." And the same respectable authority, although not insinuating "all healing" faith in the therapeutic powers of this plant, treats with great respect "The Temperature and Virtues" thereof—as follows:

"The leaves and berries of Misseltoe are hot and dray,

and of subtill parts: the Bird-lime is hot and biting, and consists of an airy and waterie substance, with some earthy qualitie; for according to the judgment of Galen, his acrimony ouercommeth his bitternesse; for if it be vsed in outward applications it draweth humors from the deepest or most secret parts of the body, spreading and dispersing them abroad, and digesting them.

KNOTT: MISTLETOE.

It ripeneth swellings in the groine, hard swellings behinde the eares, and other impostumes, being tempered with rosin

and a little quantitie of wax

With Frankincense it mollifieth old vicers and malicious impostumes, being boyled with vnslaked lime, or with Gagate lapide, or Asio, and applied, it wasteth away the hardnes of the Spleene.

With Orpiment or Sandaraca it taketh away foule ill

favored nailes, being mixed with vnslaked lime and wine

lees it receiveth greater force.

It hath been most credibly reported vnto me, that a few of the berries of Misseltoe bruised and strained into Oyle, and drunken, hath presently and forthwith rid a grieuous and sore stitch.

This author distinctly attributes poisonous properties to the birdlime obtained from mistletoe, "which because it is sharpe and biting, inflameth and setteth the tongue on fire, and with his slimie and clammie substance doth so draw together, shut, and glue vp the guts, as that theer is no passage for the excrements. Corresponding powers of mischief had been attributed to Ixia by Nicander, Dioscorides, and Paulus Ægineta-as well as by the crowd of writers who copied them—but the exact connotation of "Ixia" ever remained disputable. And the poisonous property attributed to birdlime by Gerard, is confidently denied by his editor, Johnson, who also refers to its "being frequently vsed in medicines against the Epilepsie.

The therapeutic reputation of the mistletoe continued to flourish in the Middle Ages, and we find Paracelsus, the thundering therapeutic iconoclast of the Renaissance, as furiously emphatic in his laudation of its use in epilepsy as he was in his general denunciation of the theories and practices of the recognized classical "authorities—"infallibly" estimated as they were by nearly all practitioners at

that date.

The encyclopædic English botanist and herbalist, John Parkinson—whose name is dear to bibliophiles as the author of the famous Paradisus in Sole-collected into the pages of his Theatrum Botanicum a characteristically exhaustive summary of the existing state of knowledge (and gossip) of the science and lore of the mistletoe at the date of the publication of that volume (1640). The following extracts may, perhaps, repay the attention of the curious reader, even in the twentieth century. He thus deals with "The Names"

It is called in Greek 1505 by Dioscorides, and so is the Birdlime made thereof also, and little by Theophrastus who saith also that in Eubaa it is called Stelis, and in Arwho sailt also that in Eucoda it is called Steak, and in Art-cadia, Hyphcar yet lib. 3, c, 16, of his History, he saith that Stelis groweth on the North Side of the Ilex, and Hyphcar on the South, and so they differed from one another in some thing which he hath no where exprest, in Latine Viscus and Viscum, and so also the birdlime made of the berries, as are all these sorts called by all writers, that have written either of the two last, since Lobel, with their severall adjunctes. The Arabians call it Debach, Dabuch, and Hale, the Italians Vischio, the Spaniards Liga Merda. All the Irania Mischen with Irania Mischen Mischen Mischellen, the Dutch, Marcutacken, and we in English Mischellen. English Missellto.

This highly receptive authority is found to reject the time honored notion of the deposition of the mistletoe seeds by birds:

It is since found by experience, that there is no shew of seed in that dung, they voyde upon the trees or elsewhere, being wholly altered in their bellies before the voyding, and further that Missellto groweth on trees from their own superfluous moysture, which made Ion the poet to call it Sudor quercus, even as Galles doe and Oke Apples from other sort of Okes, and haue no seede of their owne, and to this purpose Virgil Sexto Aineido saith:

Quale solet sylvis brumali frigore, Viscum Fronde virere nova, quod non sua seminat arbos.

Parkinson's account of the therapeutics of the mistletoe (and its birdlime) furnishes striking testimony to the persistence of popular opinion on subjects which furnished material for the construction of leading articles of faith to the pastors of the multitudes in pre-Christian ages. It is as follows:

Missellto is hot and dry in the third degree, the leaves and berryes doe heate and dry, and are of subtill parts, for some acrimony is in them, which ouercommeth the bitternesse, the Birdlime doth mollifie hard knots, tumours and imposthumes, ripeneth and discusseth them, and draweth forth thicke as well as thinne humours, from the remote places of the body, digesting and separating them: but is not of that property to heate suddainely, but after some time as Thapsia doth, and being mixed with equal parts of time as Indexia doth, and being inject with equal parts of Rossin and waxe doth mollefie the hardnesse of the spieene, and healeth old ulcers and sores; being mixed with Sandarack and Ortment, helpeth to draw of foul nailes, and if quicke lime and Wine lees be added thereunto it worketh the stronger. The Missellto it selfe of the Oke as the best, (or of the Chestnut tree as Matthiolus saith to be as good) made into pouther, and given in drinke unto those that haue the falling sickenesse, doth heale them as Matthiolus saith, and that he had tryed it and healed many assuredly: but it is fit to use it forty dayes together: and with this caution, that the wood after it is broken from the tree, doe not touch the ground, which is in my minde too superstitious, as is their conceit also, that it hath power against Witchcraft, and the illusion of Sathan, and for that purpose, use to hang a peece thereof at their childrens neckes: Gentiles Fulginas and others haue so highly esteemed of the vertues hereof, that they have called it Lignum sanctæ crucis, beleeving it to helpe the falling sicknesse, Apoplexy, and Palsie very speedily, not onely to be inwardly taken, but to be hung at their neckes, and some to inwardly taken, but to be hung at their neckes, and some to hang it at their neckes, or weare it on their arme to helpe them to conceive: and saith Matthiolus I have knowne ignorant emperickes, to haue giuen the Birdlime made into pilles to persons to swallow insteade of the wood: and further saith that he knew the Missellto that grew on a Pearetree, given to one that had the parts of his body drawne together, to doe him much good and divers doe esteeme of the Missellto that groweth on Hassell nuts, or Peares, as effectuall as that on the Oke so it touch not the account for effectuall as that on the Oke, so it touch not the ground, for the falling sicknesse, to be taken in Wine. *Tragus* saith that the fresh wood of any Missellto bruised, and the juyce drawne forth, and dropped into our eares that haue Imposthumes in them, doth helpe and ease them within a few dayes; the leaves are often given to cattell saith Pliny, to fatten them and purge them first: but if they be diseased they cannot continue long, this manner of curing them lasteth for forty dayes in Summer.

In his New London Dispensatory (1676 and 1684-5) the very learned and very voluble herbalist, William Salmon, devotes two paragraphs of Lib. I (of Herbs) to a discussion of the mistletoe. They are as follows:

Viscum, Viscus, Ixia Rencalmi, 'Ιξός καὶ ἰξία, Missel-Viscum, Viscum, Viscus, Ixia Rendami, 1208 xati 1203, Misseltoe, hot and dry in 3°. It is of subtil parts, and good against most of the diseases of the Head and Spleen: The Berries strained into Oyl or Wine, and drunk, help stitches, and other pains of the sides: It purgeth viscous Humours, helps Palsies and Convulsions, is Hydrotick and Antepileptic: Outwardly, it ripens swellings and scirphous Tumours behind the Ears, drawing from the deeper parts of the hody, and directing the humours: it molliest parts of the body, and digesting the humours: it mollifies old Ulcers, and ripens angry Imposthumes.

Viscum Quercinum, Misseltoe, hot and dry in 2°. It mollifies and discusses; ripens Tumour behind the Ears, and other Imposthumes mixed with Wax and Rosin. Inwardly it is a specifick in the Epilepsie, and certainly cures it, by giving as much as will lie upon a six pence or nine for some days near the full Moon.

The "Vulgar Errours" which the annals of natural history had ever associated with the life history and the qualities of the mistletoe have-inevitably-had their turn of the critical attentions of the author of the Pseudodoxia Epidemica. He tells his readers of the "creed of the Ancients" regarding the growth of the "Viscus Arboreus"; "from seeds which birds, especially Thrushes and Ringdoves, let fall," and refers to the testimony of Pliny and of Virgil. He then proceeds:

If so, some reason must be assigned, why it groweth onely upon certaine trees, and not upon many whereon these birds do light. For as Exotick observers deliver, it these birds do light. For as Exotick observers deliver, it groweth upon Almond trees, Chestnut, Apples, Oakes, and Pine trees, as wee observe in England, very commonly upon Apple, Holly, Bayes, Crabs, and White Thorne, sometimes upon Sallow, Hasell and Oke, never upon Bayes, Holly (sic!), Ashes, Eline, and many others. Why it groweth not in all countries and places where these birds are found, the contract of the countries and places where these birds are found, and the countries and places where these birds are found, and the countries and places where these birds are found, and the countries are considered. not in all countries and places where these birds are found, for so Brassavolus affirmeth, it is not to be found in the territorie of Ferrara, and was faine to supply himselfe from other parts of Italy. Why if it ariseth from a seed, if sowne it will not grow againe, as Pliny affirmeth, and as by setting the berryes thereof, wee have in vaine attempted its production; why if it commeth from seed that falleth upon the tree, it groweth often downewards and puts forth under the bough, where seed can neither fall nor yet remaine. Hereof beside some others, the Lord Verulam hath taken And they surely speake probably who make it an arboreous excrescence, or rather superplant, bred of a viscous and superfluous sappe the tree itselfe cannot assimilate, and therefore sprouteth not forth in boughs and surcles of the same shape and similarly unto the tree that beareth it, but in a different forme, and secondary unto its provided intention of the same shape and similarly unto the tree that beareth it, but in a different forme, and secondary unto its provided intention of the same shape and the same shape sha specificall intention, wherein once fayling, another forme succeedeth and in the first place that of Misseltoe, in plants and trees disposed to its production. And therefore also wherever it groweth it is of constant shape, and maintaineth a regular figure like other supercrescences, and such as living upon the stalk of others, are termed Parasiticall plants, as Polypody, Mosse, the smaller Capillaries, and

Now whatever this conceit, it might be the enlargement of that part of truth contained in the story. For certaine it is, that some birdes doe feed upon the berries of this vegetable, and we meet in Aristotle with one kind of thrush called iξoβόρος, the missell thrush or feeder upon misseltoe. But that which hath most promoted it, is a received proverb, Turdus sibi malum cacat, Applicable unto such men as are authors of their owne misfortune. For according unto ancient tradition and Plinie's relation, the bird not being able to digest the fruit whereon shee feedeth, from her inconverted meeting, ariseth this plant, of the berries whereof birdlime is made, wherewith she is after entangled. Now although proverbs bee popular principles, yet is not all true that is proverbiall; and in many thereof there being one thing delivered, and another intended, though the verball expression be false, the proverbe is true

enough in the veritie of its intention.

We find also that the mediæval opinions regarding sundry supernatural agencies which were so obstinately cherished by Sir Thomas Browne to the end of his life did not include some properties of such quality which had been attached by popular opinion to the mistletoe:

As for the Magicall vertues in this plant, and conceived efficacie unto beneficiall intentions, it seemeth unto me a Pagan relique derived from the ancient Druides, the great admirers of the Oake, especially the Misseltoe that grew the vertue whereof was to resist all poysons, and to make fruitful any that used it. Vertues not expected from Classical practice. And did they answer their promise which are so commended in Epileptical intentions, wee would abate these qualities. Countrey practise hath added another to provoke the after-birth, and in that case the decoction is given unto Cowes. That the berries are poison, as some conceive, we are so far from averring, that we have safely given them inwardly, and can confirme the experiment of Brassavolus, that they have some purgative

Such is Sir Thomas Browne's account of the opinions held by the "learned Vulgar" regarding the mistletoe in the year of grace 1646—the date of the first edition of his wonderful Pseudodoxia Epidemica. And it is worthy of note that in the last edition (sixth) of the same work that was issued in the author's lifetime, after an interval of thirty-six years, there is no notable change in the text of the paragraphs which deal with the subject of this unique plant. Indeed, he merely omits the Bayes and Holly from the list of hosts, in which they had been placed by an obvious slip of the pen, and rejects the former from that of the non-hosts also.

The great Medical Dictionary of Dr. James appeared in 1745. The expert in medical literature will recall the fact, on observing the name, that the author was the inventor of the famous antimonial "fever powder," which has been credited—among the many more creditable, if less conspicuous, items of its achievement—with having promoted the dis-solution of the most famous of Ireland's medical men. And the expert in literary history will remember that the preface to this series of massive folios was written by the great English lexicographer, the design of whose epoch making Dictionary of the English language is said to have been originally suggested by that of the medical lexicon to which it is believed that he contributed very largely. Accordingly, it is specially interesting to contrast the views of the great medical friend of Oliver Goldsmith and of Samuel Johnson with those by William Salmon and by Sir Thomas Browne, almost exactly a century before:

Misseltoe is accounted a cephalic and nervine Medicine, missence is accounted a cephane and nervine Medicine, particularly useful for all kinds of Convulsion-fits, for the Apoplexy. Palsy, and Vertigo; for which purposes, some prefer the Misseltoe of the Hasel to that of the Oak. Birdline is a powerful Attractive, and good to ripen hard Tumors and Swellings; It is an Ingredient in the Emplastrum Dischalm Magnetic Diachylon Magnum.

And further:

It has the virtue of mollifying and discussing Tumors, It has the virtue of monifying and discussing running, the Parotides and Abscesses, being mixed with Rosin, and an equal quantity of Wax; it also cures the Epinycitides, and, as Pliny says, dries up strumous Ulcers, and cures the Epilepsy. . . . The Wood is of principal and specifick Use in the Epilepsy; it is, also, prescribed for the Apoplexy and Vertigo, taken inwardly, or hung about the Neck: For these disorders it is acknowledged to be effectual, by the unanimous consent of ancient and modern Physicians. We know some, says I. Bauhine, who have made use of the Wood of Viscum, macerated in Wine, with success, against the Vertigo. The Powder of Viscum, especially what grows upon Oaks, not only cures the Epilepsy, but provokes the Menses. It is, also, an Arcanium against a Pleurisy, being taken once and again, and a third time, in Water of Cardures and Poppy.

J. Bauhine writes, that he has several times advised the use of Viscum, bruised and macerated in proper Waters, against the Worms of the Intestines in Children.

The Powder of the Viscum which grows on the Oxyacan-thus, being infused in White or Spanish Wine, and given two Hours before the Paroxysm or Fit, and the dose repeated, if necessary, has often removed, and perfectly cured, a Quartan.

The leaves, after they have been chewed and pounded by the Teeth of laboring Beasts, and Cows, are, by our rustic People esteemed effectual for expelling the Secundines.

The extracts contained in the rather congested

series of quotations collected in the above paragraphs offer a remarkable, and, I hope, fairly interesting example of the persistence, down through tens of centuries, of medical faith in the efficacy of a therapeutic agent of which the claims have been utterly discounted in the light of modern science. There seems to be but small prospect, indeed, of the future restoration of the mistletoe to the all healing position which was so loyally and devoutly accorded to it by our ancestors. Still we find, nevertheless, that recent reports prove that its therapeutic celebrity has not quite died out. It appears to be still used, in parts of England, as a popular remedy in cases of cardiac trouble. And, like the strophanthus of African arrow poison fame, it has actually been held to represent a reliable substitute for digitalis!

The prominence of the somewhat uncanny vegetable growth in the household decorations which accompany our Christmas festivities is probably due, like that of the ivy, to its comparatively succulent and suggestively productive aspect at this season of generally suppressed vegetation. The peculiar social ceremony of salutation which is so usually connected with the elevation of the mistletoe within the homes of Yuletide festivity, is one which the old fashioned practitioner would probably, I believe, not wish to see abolished. But such questions will probably be largely, if not exclusively, decided in the future decades of our century by the domestic legislation of the "New" Women, and the Parliamentary control of the suffragettes. The great majority of our adolescents at present date will, nevertheless. I venture to think, agree with the sentiments expressed in the quaint old doggerel stanza:

> "Of all the games, both rich and rare, There is a game none can compare; And that sweet game, as all you know, Is kissing 'neath the Mistletoe."

The supraosculatory position which the mistletoe has so long maintained in the minds of the youth of both sexes will probably tend to prolong its celebrity beyond that which future generations may be disposed to grant to its therapeutic properties. And as our twentieth century has hitherto proved so richly productive of medical Jeremiads on the subject of "race suicide," perhaps the suggestions offered by the presence of the overhead Viscum album, at a season specially associated with demonstrations of family affection, should not be too severely criticised as a mere relic of mingled pagan superstition and social frivolity.

34 YORK STREET.

IS NOT THE TUBERCLE BACILLUS THE CAUSE OF CANCER?

By Thomas G. McConkey, M. D., San Francisco, Cal.

Previous to Koch's discovery in 1882 the striking analogies between tuberculosis and cancer had been noted by the older writers and caused them to institute comparisons between them. But since that discovery, in spite of the search for a cause of cancer, no one that I am aware of has hitherto tried to prove that the tubercle bacillus is also the cause of cancer. After months of investigation with this hypothesis as a guide I am convinced that the tu-

bercle bacillus by virtue of its well known effect of causing cell proliferation is the fundamental cause of malignant growths. In the young and robust this cell proliferation is usually checked by a defensive reaction in the form of an exudate of lymph and lymph cells which hedges in the new growth and a tubercle is the result. But if this cell proliferation is set up in one whose defensive reaction is inadequate to hedge it in a malignant growth is the result.

This theory is based not on speculative assumptions, but well authenticated facts. First let us recall the salient facts in the histogenesis of tubercle. Councilman says: "Virchow supposed that it always formed in connective tissue by a multiplication of the cells of this tissue. It is certain, however, that no one tissue enters solely into its formation, but all the cells of the tissue, whether connective tissue corpuscles, gland cells, or the endothelium of bloodvessels and lymph vessels, take part in it." Baumgarten found that the first changes in the tissue were coincident with the appearance of the bacilli. Under their influence the fixed cells, whether gland cells, endothelial cells of bloodvessels and lymph vessels, or connective tissue cells, became enlarged. pale, and finely granular, and changed into the epithelioid cells. The earliest and smallest tubercles simply represent a collection of these epithelioid Among these epithelioid cells, which are quite closely arranged in concentric layers, numbers of lymphoid cells are found, especially in the outer portion of the nodule. A network of fibrin filaments support these lymphoid cells and also permeate the nodule. The so called "giant cells" are also seen in the majority of tubercles. The first visible sign of the presence of the bacilli is the proliferation of the epithelioid cells, and Baumgarten holds that the primary effect of the tubercle bacillus is to cause the growth of tissue by the formative stimulus which it exerts. More or less promptly a defensive reaction against this new growth in the form of an exudate of lymph and lymph cells occurs. The lymph is rich in fibrinogen and the lymph cells furnish the "fibrin factors" or "plasmmane which causes coagulation of fibrin," and this seems to be the source of the fibrillar network permeating and encapsulating the nodule. The best explanation of the "giant cells" is that they are cross sections of lymph vessels or spaces, and the "nuclei" are lymph cells caught in the lymph clot. Hektoen, though regarding the giant cell as an entity, looks upon it as a defensive agent. Theobald Smith regards the tubercle itself "as a mechanism of defense for the body, even though imperfect." structure of the tubercle, he says, interferes with the further dissemination of the bacilli by clogging the channels of escape. As a mechanism of defense is it not rather for the purpose of hedging in the proliferating focus by clogging the channels of escape and shutting off the blood supply? Bacilli are rather fought by phagocytosis. Smith believes the tubercle is a mechanism of defense for the bacillus-a mutual product, as it were. I would incline to the view that it incidentally serves the interests of the bacillus by protecting from phagocytosis and permitting it to exist in a latent state for years.

Virchow regarded the tubercle as a lymphoma, and as a heteroplastic growth it had "the prejudice of malignity." But in comparison with cancer and sarcoma "tubercle, on the other hand, is always a pitiful production, a new formation from its very outset miserable. From its very commencement it is, like other new formations, not infrequently pervaded by vessels, but when it enlarges, its many little cells throng so closely together that the vessels gradually become completely impervious. chow says that the older writers were wont to draw parallels between cancer and tubercle and that tubercle was "regarded as an incomplete and somewhat crude product and as a structure which had never become properly organized." We now know that as a new formation it is a miserable product because of the prompt reaction, which strangles its further growth.

In anticipation of the obvious objection that if the tubercle bacillus is the cause of cancer it is inconceivable that it would have thus far escaped detection I shall cite authoritative evidence which shows that the bacilli can originate lesions which give no microscopic evidence of their causation; that even in the most typical tuberculous lesions it is frequently impossible to demonstrate a single bacillus by the ordinary methods; that not only are inoculation experiments not contradictory, but are even best explained by this theory; that the tuberculous and cancerous processes are frequently found not only in the same patient, but in the same growth: that caseation which is so characteristic of tuberculosis is also found in cancer; that conditions formerly called cancer are now known to be tuber-

The following is abbreviated from Councilman: The lodgement of tubercle bacilli in the tissues is not, however, always followed by the formation of definite tubercles alone. Frequently, especially on free surfaces, the formation of abundant granulation tissue is associated with such tubercles. tissue is highly vascular, but despite the vascularity caseation occurs as in tubercle owing to the bacilli. When the process is slow, contraction and induration may result in a hard, firm, scarlike tissue, which may escape necrosis and microscopically show no indication of its tuberculous nature. Councilman also says that the bacilli "are probably more difficult to find in miliary tubercles than in any other of the tuberculous processes." And again: "In parts that have undergone complete caseation it is often extremely difficult to demonstrate the bacilli. This is especially the case in old caseous lymph glands. Often twenty or thirty sections will have to be examined before a single bacillus is found. They are seldom in groups, but only here and there one is found, and unless it lies parallel to the plane of section it is easily overlooked." Hans Much, quoted by von Behring, says "a remarkable fact that has been known for some time, but the significance of which has not been fully appreciated, is that, in the lungs of tuberculous cattle, though they are crowded with tubercles, it is frequently impossible to demonstrate a single tubercle bacillus by the ordinary methods. The same is true of the so called cold abscesses occurring in man."

In view of such facts as the foregoing would it

not be remarkable if bacilli had been found in malignant growths, especially when this theory only presupposes a minute focus where they might possibly be discovered? When we remember that they have not been looked for it would indeed be remarkable if they had been found. What better explanation of those "concentric nests" so frequently found in cancer and called "cancer nests," "bird's nests, etc., and for which there is no satisfactory explanation than that they are cross sections of old tubercles? Even a superficial examination of the results of cancer inoculation experiments reveals a surprising number showing "miliary nodules," especially in the lungs and serous membranes. Curiously enough, the age of the animals experimented on did not seem to be thought of sufficient import to be even mentioned by most of the experimenters. Now there is an age incidence in cancer in the lower animals corresponding to that in man, and doubtless if old animals had been inoculated instead of miliary nodules genuine cancers would have re-For whether these miliary nodules were sulted. caused by bacilli or were simply the result of transplanted proliferating cells, as is more likely, there was an exudative reaction which checked their further development. Space permits mention of but three sample experiments: Lebert and Toller injected an emulsion of mammary carcinoma into the jugular vein of a dog, and fourteen days later found some nodules on the pericardium. rapidity with which the secondary growth occurred was against its cancerous nature" was the comment, but would this exclude its tuberculous nature? Plimmer's inoculations in one series of animals "caused death in thirteen to twenty days with the production of small nodules consisting of the proliferating endothelial cells in the serous membranes and in the lungs." Plimmer concludes from his experiments "that certain undoubted parasitic intracellular bodies occur in carcinomata that can be cultivated outside the body." Would not the tubercle bacilli answer this description? Lanz by inoculation of cancer material produced a "group of warts in the form of a letter 'J' upon the back of his gardener's hand." Is not this analogous to the verruca necrogenica of Wilks or post mortem warts, which we know to be tuberculous? Park quotes this question from Behla: "When it is so easy to transmit cancer from one animal to another, why should it be so hard to discover its real cause?" and comments that that is truly an as yet unanswerable question. Is not the answer to this clear in the light of this theory? In transmitting cancer from one animal to another the experimenter has simply transplanted cells with the malignant habit of proliferation and the process is analogous to metastasis. There is only a very remote possibility of accidentally inoculating the bacilli that originally caused the cells to take on the vicious habit of multiplying in an unlimited manner.

Cancer and tuberculosis were regarded as antagonistic, but it has been shown that the age incidence and the localization of the two conditions are so different that any apparent antagonism is easily explained. Schwalbe has reported three cases of cancer developing in the wall of a tuberculous cavity, and Claude thinks that tuberculosis is not un-

common in cancerous deposits (Osler's Modern Medicine, iii, p. 325). Fistula in ano, which is thought to be always tuberculous in origin, not infrequently is the forerunner of cancer of the rectum. Orlovski collected 59,175 autopsy reports, 114 of which showed cancer of the lung, or 0.19 per cent., and he adds: "The tubercle bacilli may be found in the sputum of patients with cancer of the lung, as tuberculosis quite frequently coexists with cancer of the lung, as ruberculosis quite frequently coexists with cancer of the lung, says: "In the diffuse cancerous growth the condition may resemble a tuberculous pneumonia." I recall an autopsy on an old man with gastric cancer. The experienced pathologist of the large hospital was enthusiastic on opening the thorax to find, as he thought, the rare condition of cancer of the lung also, but microscopical examination revealed bacilli, and the diagnosis had to be revised accordingly.

As to caseation which is so characteristic of tubeculosis, Virchow said that "the cheesy transformation is the regular termination of tubercle, but, on the other hand, it is not the necessary one, inasmuch as there are cases, in which the tubercles, in consequence of their undergoing a complete fatty metamorphosis, become capable of reabsorption; and, on the other hand, the same cheesy metamorphosis befalls other kinds of new formations; for pus may become cheesy and likewise cancer and sarcoma. . . . In the midst of cancerous masses cheesy spots occur which look exactly like tubercles." Councilman says: "Retrogressive changes are common in carcinoma. As we have said, the juice obtained by scraping the surface always contains cells in a greater or less degree of fatty degeneration and some which are entirely broken down. . . . In other cases a condition very similar to tuberculous caseation is met with. stated before, Virchow regarded the tubercle as a lymphoma, but with the prejudice of malignity, and he placed the pearly nodules in bovine tuberculosis among the sarcomata. Lupus, which was formerly placed with the cancers, is now placed with the tu-berculous lesions. It is such facts as these that compel the conviction that there is a relationship between cancer and tuberculosis that cannot be explained by mere coincidence, but which is perfectly explained by regarding them both as manifestations of one and the same infection.

The opponents of the parasitic theory assert that it fails to account for different tumors, the mixed growths, the occurrence of different tumors in the same individual, etc. On the contrary, the present theory furnishes a probable explanation which cannot be said of any other theory. Virchow's classification of tumors was based upon the fact that every "pathological structure has a physiological prototype." He ridiculed the idea of a specific cancer cell and classified new formations upon exactly the same plan he had ventured upon for the physiological tissues. In his Croonian lecture (1803) he said: "I blocked forever the last loophole of the opponents, the doctrine of the specific cells of pathology, by showing that even diseased life produced no cell for which types and ancestors were not forthcoming in normal life. These are the fundamental principles of cellular pathology."

Manifestly the particular type or types of cells found in malignant growths is not determined by the morbific agency, whatever it may be, but by the physiological type that has acquired the tendency to multiply instead of functioning. The structure is a matter of local accident, but the tendency to undergo unlimited proliferation is the real puzzle and the very essence of the cancer question.

All malignant growths have this in common, and not only would a single cause be competent to produce this one effect, but it is improbable that more than one cause could produce such a uniform effect. It is unthinkable that the numerous varieties of carcinomata and sarcomata and the mixed forms have separate causes. Roswell Park puts it thus: "It is characteristic of cancer that its variety is very great, which is to be explained in some other way than by direct implantation of a carcinoma cell or by the preposterous statement that any somatic cell, by any intrinsic stimulus, can possibly develop de novo a specific disease such as cancer. We might as well be told that tuberculosis is due to the agency of an intrinsic stimulus." And that was actually the prevailing view regarding tuberculosis as late as 1878, in spite of Villemin's experiments in 1865, which showed its infectious nature. The very name was given it by Schoenlein in 1839, who was a disbeliever in its specific nature. Klebs considered tuberculosis an unfortunate term, and said it "is the cause of the obscurity which has so long enveloped the disease.'

Various theories to account for the unlimited proliferation of cells which constitutes the malignant quality of tumors have been promulgated. But neither the "embryonal rests" of Durante and Cohnheim nor Ribbert's "misplaced cells" are adequate to account for malignant growths, though explaining benign tumors as dermoid cysts. The recent report of the Imperial Cancer Research Fund "destroys all known theories of cancer, formulating, however, no new theory." It is common knowledge that tubercle bacilli cause cell proliferation, but I am not aware that there is any accepted theory as to how it does this. And while it may seem like an attempt to explain the inexplicable, I wish to suggest one: Whether a cell functionates or merely reproduces itself rests with the nucleus. The single nucleus of the metazoan cell is a complex structure "arising from fusion of chromatic substances which in the lower forms appear more of less independent of one another. Should, during a degeneration, an unequal loss of nuclear substance and chromatin occur in such fashion as to retain certain parts of it which are intimately connected with certain functions, while others succumb, it would necessarily allow the remaining portions to control the future of the cell" (Oertel, New York Medical Journal, lxxxvi, No. 1). Would not the primitive and dominant function of reproduction survive longer than the later acquired functions of specialization? The nucleus and its chromatin are rich in phosphorus. The bacilli require for their growth "suitable pabulum containing assimilable nitrogen and phosphorus." The nucleins comprise a special group of readily decomposed complex proteids containing phosphoric acid and form the chromatin substance of the cell nucleus

(whence the name), as well as the tangible constituents of the cell body and have a strongly acid character. A notable peculiarity about culture media for the tubercle bacilli is the high degree of acidity due to acid salts which is favorable for their growth. Nuclein has been extracted from tubercle bacilli and the decomposition of this sets free "nucleic acid or tuberculinic acid" containing from nine per cent. to eleven per cent. of phosphorus. The bacilli are found in the cells lying near the What agent other than the tubercle nucleus. bacilli could so well destroy the chemical integrity of the nucleus and bring about that "unequal loss of nuclear substance and chromatin" resulting in the loss of certain functions and allowing "the remaining portions to control the future of the cell?" Whether the facts given suggest the true explanation or not is of no great importance, but the fact that tubercle bacilli do set up cell proliferation, whether connective tissue, epithelial, or endothelial, in which they find lodgement, is of compelling significance in furnishing the solution of the cancer

problem. This theory of the ætiology of cancer is equally satisfactory when examined from the clinical side. Ballunce and Shattuck, quoted by Coley, go so far as to say that "there is no fact in the ætiology or life history of carcinoma or sarcoma that has not its counterpart in tuberculosis, and thus illustrate how near we may be to a great generalization and yet just miss it. Space will permit mention only of a few of the analogies: Both are hereditary in the sense of showing a family predisposition; both show an age incidence; both purely local at first; both may become general; both may result from trauma; both found not only in man, but in other vertebrates; both have location incidence in certain tissues; both show difference in appearance and structure, depending on tissue affected; both may have as predisposing cause depressing influences, as worry, grief, etc.; both have wasting and cachexia; both have race incidence; both have house and district incidence. These striking analogies are plain if we consider the conditions as different manifestations of one infectious agent, and the apparent antagonisms are also thus satisfactorily accounted for. Williams (Edinburgh Medical Journal, 1898, No. 10) found at autopsies old or arrested phthisical foci three times as often in cancerous as in other subjects, and concluded "that malignant disease seemed to exercise a retarding influence on pulmonary tuberculosis." We may accept his findings, but not his inference, for the findings prove rather that these persons in early life resisted the pulmonary form of tuberculosis only to succumb in later life to the cancerous form. The location incidence is very significant in the light of this theory: Tuberculosis of the lungs, pleura, and liver, for example, is very common, but primary cancer of the lungs, pleura, and liver is very rare. On the other hand, cancer of the mammary glands, stomach, and os uteri, for example, is very common, but tuberculosis of the mammary glands, stomach, and os uteri is very rare. Better diagnostic methods prove that tuberculosis of these organs is actually more frequent than formerly supposed, and we are told that tuberculosis of the os, for instance, "presents great

difficulties in diagnosis on account of the resem-

blance to carcinomatous growths. The age incidence of the two (?) diseases is most eloquent testimony to the soundness of this theory. Tuberculosis is essentially a disease of the first half of life and cancer of the last half of life. much as the lymphatic, meningeal, bone, and joint forms predominate in childhood and the pulmonary form in early adult life analogy would predicate some dominant manifestations in later adult In accord with this theory cancer is the predominant manifestation of tuberculous infection in advanced life exactly as scrofula is during childhood. Scrofula was considered a disease entity until proved to be a phase of tuberculosis. I believe we may safely assert whether tubercles or caucerous growths result lies with the efficiency or inefficiency of the lymphatic system to hedge in the proliferating focus. Physiologists tell us that "in adult and advanced life the glands (lymphatic) are usually somewhat atrophicd and darker in color.' The so called epithelioid cells we know may originate from either epithelial or connective tissue cells. and their appearance is the result of pressure and degenerative changes going on within the tubercle, but if there were no pressure or degenerative changes they would then show their origin by the type of cell dominating, as in malignant growth. Hence the varieties of cancer. It is self evident if this theory is correct that the more persons who survive the earlier forms of tuberculosis the more there will be left to succumb to the later forms. A decrease of mortality from pulmonary tuberculosis would predicate an increase in cancer mortality. For the State of New York the following figures are given by Park:

 IS87
 IS88
 1907

 Deaths from tuberculosis.
 11,009
 12,552
 13,000 (about)

 Deaths from cancer.
 2,363
 4,456
 7,000 (about)

This shows an increase in twenty years of eleven per cent. in tuberculosis and one hundred and ninety-six per cent. in cancer. The increase in population in the State from 1890 to 1900 was twenty-one per cent., and for twenty years would presumably be about forty-two per cent. In San Francisco the number of deaths from cancer in 1866 was at the rate of 16.5 in 100,000, while in 1898 it had risen to 103.6 in 100,000, or more than six times as many For the year ending June 30, 1908, there were 460 deaths from cancer, or a rate of 108.2 in 100,000, taking the board of health's estimate of the population as 425,000. For the same year there were 729 deaths from pulmonary tuberculosis, or a rate of 171.5 in 100,000. This indicates a low tuberculosis mortality, but a corresponding high cancer mortality.

Powers (Practitioner, 1899) says there seems tobe some relationship between malaria and cancer, which in many parts of the world makes them occur in inverse ratio to each other. This theory would account for this curious fact thus: Malaria directly predisposes to pulmonary tuberculosis, hence a corresponding low cancer mortality, because of the high phthisis mortality.

Bainbridge, in a review of recent cancer research, concludes thus: In addition to race, climate, to-

pography, age, and sex, the following factors seem to be more or less involved as predisposing causes of cancer: Heredity, cicatrices, traumatism, chronic irritation, and malnutrition. Taking these up seriatim we find that cancer is very rare in the negro Their susceptibility to pulmonary tuberculosis furnishes the explanation. But cancer is becoming more frequent among them, which is to be explained by their growing resistance to the pulmonary form. Climate and topography affect cancer incidence by their effect on pulmonary tuberculosis. As to age, as already stated, cancer is the predominant manifestation of tuberculosis during advanced life as scrofula is during childhood. Sex as a factor may be explained in the fact that the mammary gland and uterus are very susceptible to the cancerous process either by reason of anatomical structure or liability to traumatism, especially the uterus. Heredity plays exactly the same rôle in cancer as in the other forms of tuberculosis, a natural resistance or lack of it is the thing inherited. Cicatrices interfere with the lymph supply and thus predispose to cancer. It is stated that the resected or divided lymphatic trunks can never be traced across scar tissue, and their walls are found in a thickened and obliterated condition. Traumatism has exactly the same explanation as in the other forms of tuberculosis. Chronic irritation is a kind of continued traumatism. Malnutrition means a depleted and inactive lymphatic system and diminished resistance.

In the necessity for brevity this paper is little more than an outline, but it should be sufficient to convince even the most skeptical of the possible truth of the theory set forth. To the writer it seems only another instance of the most obvious truth being overlooked and largely because of the very fact that it lay right in the pathway.

930 Ellis Street.

THE ANAMNESIS OF SUBJECTS OF EXOPH-THALMIC GOITRE.*

By E. J. G. Beardsley, M. D., L. R. C. P. (Lond.), Philadelphia,

Assistant Physician to the Out Patient Medical Department, Jefferson Medical College Hospital.

It is difficult to find, in the entire realm of medicine, a more intricate or at the same time, more interesting subject than is the disease of exophthalmic goitre. Our minds are so constituted that the problems concerning which we are able to understand least possess for us the greatest attraction, and this is certainly true in medical science where we find the diseases of unknown or uncertain ætiology attracting the attention of both clinician and pathologist.

Despite all the attention paid this disease by trained workers in pathology it is questionable whether the present understanding as to the ætiology of the disease will remain accepted a quarter of a century hence. Whether this surmise is true or not it cannot but be helpful if each practitioner makes as careful a study as possible of each patient.

suffering from the disease who comes under his care and publishes those cases which seem out of the ordinary.

The very name exophthalmic goitre would seem to indicate that a diagnosis of the condition was easy. It would seem improbable, if not impossible, that one should overlook the presence of the swollen thyreoid gland as well as the protrusion of the eyeballs especially when in the great majority of patients with the disease we have our attention attracted by the tremor of the hands and often by the rapidity of the heart's action.

It seems but a very short time ago that the medical profession hesitated to make a diagnosis of pulmonary tuberculosis before the tubercle bacillus was found in the sputum, but since the more careful study of tuberculosis has been undertaken no physician hesitates to make a diagnosis of tuberculosis if the physical signs as well as the symptoms bear out such a diagnosis even though no bacilli are present in the sputum. In the problem regarding tuberculosis the early cases, that is those without softening and so without bacilli in the sputum, were regarded as the difficult cases to diagnosticate, and so it is in the early and undeveloped cases of exophthalmic goitre it is difficult to make the diagnosis. As an early and correct diagnosis is all important in the treatment of pulmonary tuberculosis so in exophthalmic goître the prognosis depends in a large measure upon the early recognition and treatment of the condition.

For two years it was the privilege of the writer to be associated with a physician who enjoyed a large practice at a prominent all year health resort where unusual opportunities were afforded for observing and in many instances studying a large number of health seekers. At a health resort, particularly a popular one, it is difficult to correctly estimate the relative frequency of certain diseases usually classified as rare, for, although a disease may be uncommon, in the sense that one physician even with a large practice observes but few cases in a life time, at a resort which has a floating population of health seekers it is not unusual to see such cases frequently. Particularly is this true of all nervous conditions, chronic in character, where change of climate is often advised, first, because of hoped for benefit to the patient, second, to afford a well earned rest to the overtaxed family of the patient, and, third and perhaps not least important, to give the family physician, whose patience as well as his therapeutic repertoire has been exhausted, a rest cure by "absent treatment"

Exophthalmic goitre was one of the diseases which often appeared either undiagnosticated or wrongly diagnosticated after months and even years of ill health for the patient, during which time the sufferer had often been under medical care.

A well marked case of exophthalmic goitre is as readily recognized as is a case of paralysis agitans, chorea, hemiplegia, or advanced pulmonary tuberculosis, but unfortunately all cases are not well marked. It is perhaps well that our mistakes in diagnosis live in our memories long after we have forgotten the successfully proved ones. I remember with chagrin a very bad slip up on my part in a case of by no means masked exophthalmic goitre.

Read before the Philadelphia County Medical Society, at its regular

Case, -The patient was a woman of forty-five years of age, who walked into the office complaining of difficulty in breathing and who gave a history of having spat up a small breathing and who gave a history of having spat up a small quantity of blood stained fluid following an unusual exertion. Superficial examination revealed slight edema of the ankles, the pulse was rapid, and on ausculation of the heart a systolic murmur was heard at the apex, which was transmitted toward the axilla. The patient was extremely nervous and was trembling, but I accounted for this by thinking that the trembling was caused by her, fright at register the blood in the expectated fluid. seeing the blood in the expectorated fluid.

On questioning the patient she stated that she always considered herself well, except for nervousness, for which complaint her family physician often saw and prescribed for her. I remember now that with the self assurance of

for her. I remember now that with the self assurance of a young and inexperienced man I was quite sure that an explanation of all her symptoms could be found in this hitherto undiscovered cardiac lesion.

The after history of the case is of interest, but is not a credit to my powers of observation. The patient was placed at rest in bed and visited and examined daily for three The heart condition was particularly studied, and although its action was still labored and rapid, despite the local application of cold as well as internal medication, as

local application of cold as well as internal medication, as the more troublesome symptoms disappeared I found, for a time, no reason to change my diagnosis.

Three weeks after my first visit I called just at dusk before the lights in the patient's room had been turned on and in the half light of the darkened room the telltale widening of the palpebral fissure was all too evident to my astonished gaze. An examination of the throat revealed the presence of a well marked goître which the patient had noticed off and on for twenty years, but she had never observed nor had she been told of any prominence of the

eyes.

This patient has been under my care for three years and during which time I have gathered from herself, her family, integrating history, which I am led to

and her friends an interesting history, which I am led to believe is not uncommon in instances of this disease.

The patient was born of healthy parents, her mother being still alive and healthy except for nervousness, the father dying of pneumonia in early adult life. The patient was periectly healthy until the birth of her second child, which was born a "blue baby." This occurrence so shocked the patient that she was very ill for some weeks, and she remembered that although the physicians were unable to deremembered that although the physicians were unable to de-termine the cause, she had a fever at this time and the swelling of the thyreoid gland made its appearance for the

first time.

Following this illness it was noted by her family and friends that the entire nature of the patient appeared changed. From a bright, happy woman she became morose and un-From a bright, happy woman she became morose and un-happy, and without apparent caused formed violent dislikes for those about her. She was under medical care for ner-vousness, etc., and at intervals of several months would become violently ill. The attacks of illness were usually preceded by psychic disturbances, during which time the patient would sometimes lock herself in her room and cry patient would sometimes lock herself in her room and cry for hours over some fancied insult or imagined neglect by her family. Vomiting, without apparent cause, and often difficult to control and frequently accompanied by diarrhoza, would suddenly occur. Other attacks were not so severe, and consisted of sudden feelings of dizziness, sometimes coming without warning, but more often produced as a result of fright, grief, or anger. One strange symptom noted all through the years of ill health of this patient was a fear of falling from a height. So marked and uncortaint a fear of falling from a height. So marked and uncontrollable was this fear that the patient was unable to take a journey either by carriage or railway without being in great distress, and often having what her friends called "nervous attacks." In the intervals of these many nervous seizures the patient considered herself a well woman, but was thought by all her friends, as well as her family, a victim "nerves

She consulted many physicians at various times and was treated for a variety of conditions, among them stomach trouble, organic heart disease, hysteria, neurasthenia, etc., but was looked upon by the majority of the physicians whom she consulted as a "very nervous woman." This patient's life for the past fifteen years had been anything but a desirable one to either herself or her family.

Looking backward on the history of the case, it is perfectly evident that during all these years the patient's physical and mental health had been poisoned by the pathological secretion of the thyreoid gland, but although the patient lived in a large eastern city and was under the care of men of reputation the cause of her difficulty was not discovered until the condition had existed for years and was far advanced.

It is the part of wisdom not to make the same mistake twice. I have taken a special interest in cases of exophthalmic goître since that first experience, and have taken care to ascertain as carefully as possible a history of the patient's life before the present illness began, and have been astonished in not a few cases to find that five, ten, and even fifteen years before the diagnosis of the condition was made these patients were under medical care for ills that in the light of subsequent events could have been due to nothing but the altered secretion of the thyreoid gland. I remember very well the case of a patient. wife of a western physician who was sent to the sea shore for the benefit of the climate and to be treated for a chronic gastric disturbance which had not yielded to treatment. Her history was that for several vears she had suffered from what she termed "nervous indigestion," which caused frequent and repeated attacks of vomiting. Examination revealed an enlarged thyreoid gland, a slight degree of exophthalmus, a slight tremor, and a persistent tachycardia. Love and the familiarity of close association had blinded the professional eyesight of the husband in this instance, but it is more difficult to understand why the patient could have been under the care of a well known internist for treatment of the stomach trouble without the true nature of the condition being discovered.

In private practice the reason why these partially developed cases are overlooked is without doubt careless methods of examination, but private practice is not the only place where this disease goes undiagnosticated. Through the courtesy of Dr. H. A. Hare, of the Jefferson Medical College Hospital, I was able to investigate the old histories of several patients who are now typical examples of Graves's disease and who appear at the out patient department of the hospital for treatment. In six of the histories of patients who afterward became typical cases of exophthalmic goître no suspicion of the true nature of the illness was recorded, but in five of the six the note was made that the patient was exceedingly nervous during the examination. three histories the diagnosis was marked exophthalmic goître followed by an interrogation mark. One of these patients returned nine months later with the characteristic facies, there having been no exophthalmus at the first visit. Another patient also returned after one year's absence, and now presents all the classical signs of the disease. Each of the last mentioned patients gave significant histories of previous ill health extending over a period of years, but although each patient was aware that at times the swelling in their throats accompanied their "bad spells" they did not consider the matter of sufficient importance to call the attention of their attending

In twenty cases of this disease of which I have complete records in only two did the symptoms begin abruptly. In one case a severe fright was the

physicians to this phenomenon.

apparent cause, and in the other the grief of a mother over the sudden death of her only daughter by accident. In both cases the symptoms appeared within a few hours following the mental strain. Of the eighteen remaining patients fourteen gave a history of over eight years of ill health before a correct diagnosis was made, while the symptoms of the four cases remaining have apparently developed within five years. Of the eighteen cases, twelve patients have been more or less continuously under treatment for gastric disturbances and nervousness. while six had been treated for organic heart trouble. It seems but reasonable to believe that in the ordinary case of exophthalmic goitre there is, as in other diseases, an incipient stage where only a very careful examination and a thoughtful consideration of the history make a positive diagnosis possible.

Certainly it is true that only in this early stage of the disease do we find our medicinal agents of value. That a certain percentage of the incipient cases never develop, while others remain latent until some severe strain upon the nervous system causes their

development is equally true.

During the past five years two very important aids to early diagnosis have been brought forward. The first suggestion is made by Emmerson, of Johns Hopkins Hospital, who advocates the administration, in these undeveloped cases, of five grains of thyreoid extract three times daily while careful notes are made as to any exaggeration of the symptoms. If the case is one of Graves's disease there is invariably an increase in the pulse rate and often an increase in the exophthalmus. The exaggeration of the symptoms soon disappears in cases of the disease, while no symptoms are noted in patients suffering from other diseases. I have had occasion to try this method three times in which there was a degree of doubt and found it most helpful.

The second aid to early diagnosis has been advocated by Kocher, who has found what he thinks to be a characteristic blood picture in Graves's disease. He states that in each of one hundred cases of the disease in which he studied the blood the leucocytes were below 5,000 to the c.mm., that the polymorphonuclear are decreased, while the lymphocytes are much increased. If this is found to be true in all cases the examination of the blood will be a very

important aid in the borderline cases.

Despite our advance in knowledge concerning the pathology of this disease, the treatment, whether by ordinary medical measures combined with rest, forced feeding, and change of climate, sera, or by the more recently advocated surgical measures, still leave much to hope for in the future. Of one thing we are all sure, and that is whatever our line of treatment the greatest hope for success lies in the hope for better results from treatment necessitates that we use every precaution to make our physical examination complete and educate ourselves to recognize the early and undeveloped cases of this disease. It is necessary for us to remember that in this disease, particularly in its early stages, we do not have the four so called cardinal symptomsthat is, goitre, exophthalmus, tachycardia, and treated. Air on and are the absent at some

stage of the disease, although there is in the great majority of cases tachycardia. Any of the other signs and symptoms may be absent, while perhaps as significant as any of the cardinal signs are the various nervous symptoms and mental irritability exhibited by the patient.

2030 CHESTNUT STREET.

H.EMORRHAGES INTO THE VITREOUS BODY IN THE ADOLESCENT.

With Report of Two Cases.

By Julien A. Gehrung, A. M., M. D., New York,

Assistant Surgeon, New York Eye and Ear Infirmary, Assistant, Vanderbilt Clinic, College of Physicians and Surgeons; Assistant Surgeon, St. Bartholomew's Clinic, etc.

The period of adolescence is probably the most important for both sexes, because of the awakening and growing desires, duties, and responsibilities pertaining to the rapid transition from childhood to adult life.

Hereditary tendencies are more pronounced at this period than at others and may render the individual more prone to a morbid state of health and

consequently to hæmorrhages.

Sex does not appear to exert any marked difference in the production of diseases of the eye during infancy and childhood. On the advent of puberty, with the accompanying menstrual losses in the one and the seminal emissions in the other, both of which are instrumental in lowering the strength and power of resistance, the difference becomes very marked. The individual is especially prone to hæmorrhages, with abnormal action of the heart and abnormal tension in the vessels, especially when combined with abnormal nutrition of the latter.

Causes: The causes of hæmorrhage into the vitreous in the adolescent, it seems to me, may be reduced to two, namely: 1, Defective nutrition; and

2, traumatism.

Defective nutrition consists in insufficient or improper supply in proportion to the demand, or improper assimilation and elimination, increased demand in proportion to quantity and quality of supply, whether from developmental or dyscrasic causes, and the improper elimination of toxic material. The dyscrasic causes of the morbid condition of the blood and tissues subsequent to diseases whereby their resistance is impaired may be inherited or ac-

quired.

Traumatism may be external or internal. External traumatism consists of injuries from blows or concussions, direct, and indirect; rapid changes in temperature, or prolonged exposure to extremes of temperature; occupations causing great fatigue and muscular strain, such as stooping, violent exercise, coughing, sneezing, etc. Internal traumatism consists in a, intraocular, diseased bloodvessels, and eye strain; b, general, fluctuations, depletion or congestion occasioned by sexual excitement, fright, hysteria, nervous shock, anger, cardiac disturbances, plethora, and anæmia—in short, any condition which can vary the blood pressure in the eye abruptly.

Suppressed menstruation is not de facto a cause

of haemorrhage. It may merely signify that the generative organs are anæmic, with a corresponding hyperanæmia or congestion elsewhere, e. g., the head.

Males are more liable to hæmorrhage than females. Von Gräfe noticed this fact in 1854.

In apoplectiform hæmorrhages alterations in the walls of the vessels are held to be the cause. Abadie denies this, and affirms that it is vascular distension which causes the rupture. Abadie also affirms that "it is very rare that at or before the age of thirty years the bloodvessels are degenerated." Bourgeois sides with Abadie because the pain of trigeminal shows an irritation of this nerve and its vasodilators, as the glaucomata are consequences of the vasodilation.

Simple increase of tension is not sufficient to produce hæmorrhage; if this was true almost every case of glaucoma would be hæmorrhagic. Neither is it necessary that the walls of the vessels be degenerated, as cases of faulty development seem only to require the exciting causes to rupture. Secondary glaucoma is not always present, and so cannot be the cause. The negative results of examination of the heart and vessels may simply mean that pathological conditions are not demonstrable.

Résumé of opinions as to predisposing causes of hamorrhages: Menstrual disturbances, anæmic contaction, constipation (Eales); gout (Hutchinson); hypertrophy of the heart (Goutard); toxæmia (Panas); acute anæmia (MacKenzie); azoturia and phosphaturia (Traneau); pernicious anæmia (Niedringhaus, Sargeant, Eales); leuchæmia (Steuben, Deutschmann); scorbuttus, malaria (cured rapidly with quinine) (Galezowski, Teillaio); renal, diabetic, and septic diseases, hereditary, also acquired, tuberculous, specific; indigestion, chlorosis, and diseases of malnutrition, imperfect development, incomplete development, overdevelopment, vascular disease neuroses, meningitis, fright, shock, injuries, trauma, etc.

Some hæmorrhages result from obstruction to the retinal circulation, endophlebitis obliterans of Wernemann. This obstacle may reside in any of the temporal or nasal branches of the retinal veins, and the obliteration may be caused by the ectasia of the posterior pole in progressive myopia.

Some deny that hæmophilics have hæmorrhages into the vitreous (Evenbuche, Valude, Abadie), but Vialet and Weber report one case in a hæmophilic, with hæmophilic parentage, having intraocular hæmorrhages which he attributed to the hæmophilia. Weber had a hæmophilic case with intraocular hæmorrages followed by optic atrophy. Eleven years later the other eye was affected; exophthalmus, with necrosis of cornea, finally phthisis bulbi resulted.

Lagrange does not agree with Abadie that hæmorrhage in these cases is due to dyscrasias of the blood or that hæmophilic blood is dyscrasic, but affirms that there is some dyscrasia of the deep membranes. He agrees that in adolescence hæmorrhage is due to alteration in the blood.

Symptoms: Prodromes are often wanting. Sudden blindness is frequently the first symptom noticed. Sometimes, however, there are repeated attacks of dimness of vision, menstrual vagaries, epis-

taxis, dizziness, bursting headaches, sense of fullness on stooping, eyes puffy in the morning, with rings around them, face pales or flushes easily, perspiration, cold extremities (circulatory disturbances), depressed and melancholy spirits, rapid growth, fatigue, nervousness, difficulty of using the eyes for near work, nocturnal seminal discharge, and epistaxis. Epistaxis is absent during hæmorrhagic áttacks. Often there is red color before the eyes. Sometimes suddenly on awaking in the morning the patient is blind in one eye, no pain, no apparent cause (the position of lying down is possibly an exciting factor).

Why is the eye peculiarly subject to hæmorrhages? Other organs are often the site of hæmorrhages, but in them they are not so noticeable to the patient or physician; they are of less consequence, more quickly resorbed, and interfere less with the functions than when in the eye. Hæmorrhages in the eye are painless, and would come and gradually disappear again unnoticed were vision not inter-

fered with.

The eye is intimately connected with the brain and subject to many of its variations of pressure and nutrition; and diseased conditions of all kinds are quickly manifested there. It is a veritable barometer of brain disturbances. No organ of comparative delicacy in the human economy is subject to such sudden, unremitting excursions, and such violent muscular action, and variations of pressure as the eyes.

On examination in cases of hæmorrhage the vitreous is found to be full of blood. The anterior portion of the eye is mostly clear from the posterior capsule of the lens forward; the conjunctival and ciliary region is as a rule not even congested. Dr. Kipp reports a case in which there was ciliary congestion, and Zieminski, a subconjunctival ecchymosis four weeks previous to hæmorrhage. morrhages into the anterior chamber are rare (see author's case). In the other articles these are conspicuous by their absence. Little tendrils of blood may be seen worming their way in the fissures of the vitreous in the early stages, increasing till the vitreous is filled, permitting no fundus reflex and obscuring vision. Sometimes there is a little light in the upper and outer parts of the retina above the hæmorrhage, probably on account of the gravitation of the effused blood. On oblique illumination the fundus shows a reddish brown reflex on the posterior surface of the lens. Later the iris may lose its lustre and color, and be marked with reddish brown streaks, the pupillary edge presents a brownish network due to absorption of blood pigment. The pupil is dilated and the eve tension is increased. The blood disorganizes, forming floating opacities or dustlike particles.

Treatment has given poor results in chronic cases, while in acute cases, after months of patient treatment, most of the detritus is absorbed, and if the destruction of the vitreous proper has not been too great, vision may be restored.

The hæmorrhages may be from the veins, burrowing along the sheaths of the vessels, forming filliform hæmorrhages, which may increase r appear as multiple ancurvsms.

Gräfe witnessed a hæmorrhage from the retinal veins which occurred while making an ophthalmoscopic examination. The blood poured slowly in a serpentine way into the vitreous. He cautions that the examination be not tedious nor unnecessarily prolonged. Hæmorrhages coming from the periphery may be sudden and copious. There may be a general exudation, an exosmosis, a diapedesis from all the veins or arteries, or possibly merely exudates of lymph. These pictures, as to number of foci, seat, disposition, and their extent, vary in different subjects.

Investigators disagree as to the origin of the hæmorrhages. Some writers, especially the Germans, think that they come from the sheath of the optic nerve, originating either from the papillary vessels or the intravaginal space, and so into the vitreous. This is improbable, as the blood could not pierce the lamina cribrosa, but would more easily invade the subarachnoid space, and course along the nerve. Others think they come from the retinal veins of the fundus. While still others say they come from the peripheral veins, from the vena vorticosæ, the ciliary body and neighborhood. The retina is merely a thin membrane, easily ruptured. The blood supply is great, and the parts subject to frequent and marked fluctuations. It seems most probable, therefore, that the majority of hæmorrhages are from the latter places. The ciliary body is very vascular, muscular, rich in nerves, and in almost constant activity, due to accommodative efforts. If the hæmorrhages have their origin from the retinal veins a clot may be just over a vein, and in later stages a filament of exudate may project into the vitreous, attached to the vein at the site of the rupture. The retina becomes thickened and white in patches, from which may radiate numerous streaks of exudate. This is known as the retinitis proliferans of Manz.

Abadie observed the beginning of a hemorrhage. Streaks of blood along the walls of the retinal vessels spread out in sheets and invaded the papilla and retinic zone, while others in form of spots in-

vaded the equatorial zone.

Hæmorrhages in the adolescent often form a sheet betwen the retina and vitreous without infiltrating the retina, e. g., subhyaloid hæmorrhages. Panas speaks of simple hæmorrhages of adolescents as "epistaxies intraoculaires."

The site of a lesion may be determined by perimetric examination. There may be other causes for the scotoma found, rendering the result doubtful.

Complications, aside from causative factors, may be secondary glaucoma, chorioretinitis, and iritis, to the extent of destruction of the eye from phthisis bulbi. Detachment of retina is rare. Bourgeois observed that small hæmorrhagic foci and some white spots were the only symptoms in a case where the urine showed diabetes. H. Jackson referred to one case of meningeal hæmorrhage in a young man, subject to epistaxis, in which a clot was found in the eye. Myopia (acquired) was noticed in a number of cases which were said to be normal, or nearly so, before the hæmorrhagic attack. In some cases hyperopia existed previously to the effusion (Zieminski). In cases in which glaucoma follows hæ-

morrhages into the vitreous or retina, or in hæmorrhagic retinitis, the eye is in all probability predisposed to glaucoma. While hæmorrhages which accompany or follow glaucoma indicate diseased bloodvessels, unless complicating operation, in which case it may be due to the too sudden release of tension.

Classification: Abadie classifies the hæmorrhages as follows: 1, Abrupt hæmorrhages with repetition. 2, The drastic hæmorrhages with rapid evolution, progressive but more insidious than the first. Instead of being resorbed in a short time, they suddenly reappear. Such cases develop slowly either toward disorganization of the eye or cure, according to treatment employed, etc. 3, Hæmorrhages dependent upon previous lesions of the deep membranes, e. g., chorioretinitis. The hæmorrhage then becomes a secondary consideration, as it is a complication of the previously existing disease. 4, Apoplectic form, due to rupture of retinal vessels not in sequence to the fragility of the vessel walls, but because of the excessive dilation.

LeGrange's classification: I, The eye is healthy and the subject is sick. 2, The eye is sick and the subject is healthy. 3, The eye is sick and the subject is sick. He objects to the classification adjective to dyscrasis, etc., as indefinite, and suggests the

preceding.

Bourgeois's classification: 1, Secondary hæmorrhages, e. g., chorioretinitis. 2, Apoplexies of the

retina. 3, Dyscrasic hæmorrhages.

To all these conditions we must add the disease "adolescence." We must admit that it is sometimes a diseased state producing marked tendency to hæmorrhage requiring only an extraneous exciting factor.

Treatment: 1. Prophylactic. Children with inherited diseases or tendencies must be carefully watched and properly treated. Any nervous manifestation or abnormal conditions in girls not directly attributable to some cause should direct the attention to the generative system, and any defect, however slight, should be properly corrected. Children of either sex rapidly attaining their growth should excite the alarm of the doctor and parent rather than admiration. They should be treated as convalescents, by diet, exercise, etc. By avoidance of exposure to rapid changes of temperature or prolonged exposure to heat or cold, overfatigue, hunger, exposure to disease, and infections. Errors of refraction should be corrected, and all occasion to eve strain avoided. Careful inquiry should be made as to cause of headaches, dizziness, epistaxis, etc. Mental and physical rest should be given during menstruation.

2. During hæmorrhage: Avoid unnecessary or prolonged ophthalmoscopic examination. Command absolute rest in a darkened, quiet room. Keep the howels open, and maintain free elimination. Give low but nourishing diet. Maintain even temperature. Deplete the head by cold applications, position, and pediluvia. Avoid recumbent positions, as it seems to be an exciting factor to intraocular hæmorrhages. Some recommend venesection, but this is objectionable. Leeches to the temple are necessary for immediate effect, as well as cold applica-

tions. There should be a light, gentle pressure bandage on eye, to act practically as a splint and hæmostat. Some give hypodermic injections of pilocarpine and eserine, also ergot and quinine, especially in malarial cases. These remedies should be used with great caution and tentatively, as they may produce a contrary effect. Ergotin, strychnine, belladonna are held by some to be of no value in these cases. Give bromides, small doses of iron (rational) as tonic; treat heart and all exciting factors. Do not excite or alarm patient, but console and encourage him.

3. Treatment of posthæmorrhagic state: Hot compresses on the eyes to hasten absorption and stimulate circulation; good food; potassium iodide, possibly combined with mercury. Treat all dyscrasias and exciting factors. Continue hygiene, quiet, etc. Abadie recommends extractum chinchonæ, ferri chloridum, sulphuric acid, acid lemonade ad libitum. He considers this better than potassium iodide or sodium salicylate. Vignes likes sodium iodide, by injections. Panas gives arsenic in the form of Fowler's solution. Bourgeois, in DeWecker's clinic, recommends injection of the salts of mercury into the buttocks.

The question of cerebral apoplexy must be considered and guarded against. Potassium iodide must be used cautiously, as it produces engorgement of

the head.

Glaucomatous conditions require very careful treatment. Operative treatment is dangerous, as the sudden lowering of tension may excite hæmorrhage, with grave results. Even rapid results from eserin

may be harmful.

If the intraocular vessels are diseased the congestion and ædema following iredectomy for glaucoma are likely to last longer, and retinal, choroidal. and neural changes increase, and the glaucomatous conditions become aggravated. Sometimes the tension becomes so great and painful as to necessitate enucleation. Hutchinson reports such a case.

Zieminski had a case with glaucomatous complication. Medical treatment and paracentesis was performed, which relieved the patient for twenty-four hours only. "The return of all the symptoms forced us to make an iredectomy with satisfactory results. The symptoms having disappeared, the

blood resorbed rapidly."

Prognosis: Prognosis is grave in proportion to the amount of hæmorrhage and location. The blood resorbs slowly; acts like a foreign body by its continuous presence in the vitreous, the aqueous becomes irritated and loaded with fibrinogen and provokes a proliferating inflammation, causing an afflux of leucocytes. Detachment of retina rarely occurs. Small hæmorrhages may remain between the vitreous and the retina and slowly resorb. The extravasated substance may become organized into white patches toothed and fringed, producing scotoma. The blood is resorbed in the vitreous more slowly in proportion as the effusion is more distant from the ciliary

The likelihood of a recurrence of the hæmorrhage makes the prognosis grave. However, many cases are reported, in which, even after several recurrences of extensive hæmorrhage, the vitreous clear-

ed and vision became normal.

The writer wishes to report two cases:

CASE I.—Patient was seen in Dr. Hunter's service of the New York Eye and Ear Infirmary. Subhyaloid hæmorrhage in a woman, twenty-eight years of age, tall, brunette, married, no children, no miscarriages, menses irregular, sometimes a week or more overdue, and quite copiregular, sometimes a week of more overduc, and quite coordinates outs. Patient stated that she had suffered considerably from "female weakness," backache, etc. There was no history of epistaxis nor specific trouble. She had had frequent attacks of rheumatism, was anæmic, poorly nour-ished, and nervous. Family history was negative.

One week before presenting herself at the clinic she awoke

in the morning, suffered no pain, but noticed that she could not see the face of the clock with the right eye. Peripheral vision good. Vos. 20/20+Fundus: In the mascular region there was a large hæm-

orrhage, perfect purse formation, as is beautifully depicted in Liebrecht's Ailas. Sharp upper border horizontally a little above the level of the disc. By playing the light over the edge of it a sharp shadow was cast on the retina. The lateral edges gradually curved, meeting each other below, and below the level of the disc. The transverse measure-ment was about four or five disc diameters, vertically about three. Several days later the hæmorrhage was the about three. Several days later the næmorrnage was the same size, slight extravasation into or over the retina, very thin layer towards temporal side. The main clot was still quite distinct. Vitreous was not invaded.

After two days most of the blood outside of the main purse clot had been absorbed, and purse formation was again complete. Where the extravasated blood had been

there was a slight, whitish mottling, rather stellate. A few whitish spots, quite small, seemed to be in the main clot. A large physiological cup existed absolutely free of blood. The origin of the hæmorrhage in this case must be in the

retinal vessels.

Patient was given potassium iodide, hot baths, bowels were kept freely open, good diet, quiet, dark, tonics.

Uranalysis showed faint trace of albumin, probably due

to presence of pus Since writing the report patient has almost entirely re-

This case seems to be one of adolescence, as the history given corresponds to cases reported by

others, and no other cause is patent.

The fields, shown in Fig. 1 and Fig. 2, were very kindly taken by Dr. Alexander Duane on his tangent plane at 30 inches from eye. Object, 10 mm. white ball. The field taken February 1, 1908, shows the absolute and partial scotoma, beautifully depicting the partially absorbed margin of clot, and the denser centre. Field taken April 27th shows only a partial scotoma, in harmony with picture of fundus, as clot is mostly absorbed and quite thin.

CASE No. II.-Hæmorrhages into the vitreous body following stab wound in temple, not touching eye; with the rare complication of hæmorrhages into anterior chamber. Case seen on Dr. P. A. Callan's service of the New York Eye and Ear Infirmary, who kindly permitted me to pub-

Mr. C. M., twenty-nine years of age, Finlander, carpenter. Patient was not well nourished. His right eye had been struck by a foreign body, eleven years ago, lodging in lower middle portion of iris and lens, producing traumatic cataract. Cataract and foreign body were removed seven mouths ago, no complications resulting.

On August 28th patient was stabbed in the left temple, one On August 20th patient was statober in the temperature inch behind margin of orbit and one quarter inch above median line. Wound probed, bone intact. There was a hearmorrhage into the vitreous body. Fundus was not visible. Vos = 6/200. Treatment: Rest, atropine, and cold

September 3rd. Patient was discharged, slightly improved, vitreous body still containing much blood.

Patient improved rapidly until October 3rd, awakened

with "fog over eye."

October 4th. Eye totally blind. Not even light perception. Vitreous body full of blood and marked hyphæmia. October 10th. Blood mostly absorbed.

Skiagraph, made by Dr. G. A. Dixon, was negative.

October 22d. Fresh hæmorrhage into the anterior chamber. V= barely light perception. T= slightly subnormal.

Injection not marked.

November 6th. Anterior chamber still cloudy, small amount of blood remaining, vitreous body very cloudy.

Fundus not visible. Patient had taken potassium iodide, and had subconjunctival injections of normal saline solution, and also of dionin. As absorbents quinine and iron, and suprarenal extract as tonic and reconstructant. Atropine locally. (Since this was written he has had recuirences.)

This is evidently a case of intraocular hæmorrhage of adolescence induced by the contre coup of the stabbing. The bloodvessels were in poor nutrition and unable to withstand the violence and sudden change in blood pressure. Later on, after lying down, with the corresponding increase of blood pressure, these vessels again gave way, with the resultant recurrent hæmorrhages. One interesting factor in this case is the repeated involvement of the vessels of the iris. This is a rare complication.

Conclusions: 1. Hæmorrhage into the vitreous body during adolescence is quite frequent, and owing to the danger of recurrence, and tissue changes in the eye, is a dangerous condition, worthy not only of patient, careful, and exhaustive treatment after the occurrence, but also of prophylactic measures.

2. The too rapid development of children should cause solicitude.

3. Rapid changes of temperature and prolonged exposures to heat or cold are ætiological factors.

4. Menstrual disturbances, undue sexual excitement and abuse, cardiac disease, dyscrasias, malnutrition, errors of refraction, all causes of eve strain, hereditary diseases and tendencies, vascular diseases, anæmias, abnormal (premature?) development, or malformations, all mental and physical causes of sudden and rapid fluctuations of the blood stream and tension are causative factors in intraocular hæmorrhages.

5. The origin of hæmorrhages may be from the retinal vessels or from the vessels in the region of the ciliary body, not from the sheath, etc., of the

optic nerve.

6. Glaucoma is rather the result than a causative

factor of these hæmorrhages.

7. The treatment should be medicinal if possible, the knife to be used only as a dernier resort.

8. Attacks in women usually follow menstrual disturbances

9. Where there is a tendency to epistaxis and this suddenly ceases we have a danger signal of hæmorrhage.

10. Males are more liable to intraocular hæmorrhage than women; normal menstruation is seemingly a safeguard.

11. The age from puberty through womanhood, or manhood, is a danger period.

12. Anæmic conditions are predisposing.

I desire to acknowledge my indebtedness to Dr. J. E. Weeks for suggesting the subject of this article and valuable advice in its preparation; to Dr. Alexander Duane for his kindness in making the "fields," and to Dr. P. A. Callan and Dr. Dwight Hunter for their courtesy in allowing me to publish these cases seen in their clinics.

II EAST FORTY-EIGHTH STREET.

LUMBAR PUNCTURE IN OTOLOGY.

By Seymour Oppenheimer, M. D.,

New York.

In the great majority of aural affections seen by the otologist, the admissibility of lumbar puncture as a diagnostic aid need not be considered, as it is neither indicated nor does it present any degree of usefulness. But in that group of cases where, coincident with or following suppurative changes either in the middle ear alone, or, more frequently, the middle ear and mastoid tissues, serious pathological changes are suspected in the intracranial structures, every diagnostic aid that can be made available must be considered, and in such instances this procedure may be the essential factor in clearing up the nature of the conditions present.

That lumbar puncture as a diagnostic agent in some of the intracranial complications of suppurative otitis has a decided value has been repeatedly demonstrated, not only in greatly aiding in the recognition of a meningitis, where it gives positive evidence of the condition present, but it is of value, as will be seen more fully later, in a negative aspect. While in some obscure cases one may be enabled by this procedure to determine the nature of the meningeal changes and to some extent their cause, by an analytical and bacteriological study of the cerebrospinal fluid, and thus obtain fuller information as to the advisability or not of operative procedures, it does not seem advisable that lumbar puncture should be employed indiscriminately in all cases of suspected intracranial complications from suppurative otitis, but its use for diagnostic purposes should be limited to such cases where serious doubt exists as to the presence or absence of meningitis, and in which it is impossible to obtain a satisfactory diagnosis without its use. While there is the possibility of added danger from its employment, yet it is trivial as compared with its value as a diagnostic agent in some instances, and as it is readily performed, it should always be remembered as a valuable aid to the otologist.

Its importance from a positive aspect is self evident, as when the withdrawn fluid shows changes from the normal varying in degree from marked turbidity, or possibly a purulent fluid, to that almost or but slightly altered, one can readily determine the nature of the intracranial changes and determine to a great extent the feasibility of operative procedures in the given case, and to a considerable degree, the prognosis. While, as has been demonstrated, the presence of but slight change in the fluid is not necessarily of grave prognostic import, even in the presence of serious local symptoms, as even in such cases, with the evidences of meningeal alterations thus obtained, operative procedures may be available, and at least in a small percentage of such in-

stances, be successfully accomplished.

The negative evidence obtained by lumbar puncture in otology also may possess great diagnostic value, for, as a rule, it indicates the absence of a meningitis of any extent, and thus eliminates this factor from the conditions suspected to be present. In a few recorded cases, however, this has seemingly been disproved, as a purulent meningitis has been found at autopsy, but it has been limited in extent and has not attained sufficient progress to infect the entire cerebrospinal fluid at the time at which the puncture was made. On account of this discrepancy in the pathological findings, it is undoubtedly the best practice to consider a normal fluid as of no diagnostic value for the time being, and if the case is such that twenty-four or forty-eight hours' delay may be safely considered, to again puncture, and if the fluid still remains clear, to consider that meningitis is not present; while other conditions being equal, operation would not be contraindicated. If delay is impossible, however, a normal fluid obtained at the first puncture would not necessarily contraindicate immediate operation, if other symptoms were present clearly indicating that the mastoid and possibly the cranium were the seat of morbid changes. It is not always, therefore, to insist in otological cases that no conclusion should be drawn from negative findings.

Quantitatively one may obtain some evidence of the presence of increased intracranial pressure by an excessive amount of fluid escaping through the cannula employed in making the puncture, but this evidence is of little or no value in the conditions met with as aural complications and for which lumbar puncture would be employed, although some value should be attached to the escape of the fluid under apparently high pressure, as undoubtedly indicating

increased tension.

To the color of the fluid one can attach no practical value, while the same may be said of its specific gravity, but the proportion of albumin present is of great diagnostic import, as an increase above the normal shows, with but few exceptions, the presence of meningeal inflammation. When numerous cells are present in the fluid, one may be sure that inflammation is the cause of the cellular exudate, while the finding of microorganisms leaves no doubt of the existence of an infectious meningitis, and this is especially so when tubercle bacilli are found, as under such circumstances a tuberculous meningitis alone can produce this condition.

The amount of fluid removed at any one time may vary from one to one and a half ounces, but for diagnostic purposes but a few drams are necessary to determine the conditions present, and the amount withdrawn is immaterial in this respect, but when this procedure is employed as a therapeutic measure the amount depends entirely upon its effect on the

patient at the time of the lumbar puncture.

While this procedure has not been employed in any large series of cases by otologists, yet it has been used sufficiently often for the diagnosis of some of the intracranial complications of suppurative of tits to form fairly definite conclusions as to its apparent harmlessness in this class of cases. It has been suggested, however, that there exists some danger of drawing infectious material from the

danger of drawing infectious material from the cranial cavity into the spinal canal in cases where the former is infected; that this may be a possibility it is impossible to deny, although in such instances no harm could arise further than that already present, as a purulent meningitis in itself would, in but a very short time, infect the spinal canal as a matter

of course.

As a basis for comparison with the varied morbid

products found in the fluid which has been withdrawn from a case of intracranial infection, it will not be out of place here to briefly state that the normal cerebrospinal fluid contains but a small trace of albumin, usually varying between 0.25 and 0.1 per cent., or at times even less than this, while it should be perfectly clear, depositing no sediment on standing. At the same time there is an entire absence of any cellular constituents, and fibrin should also not be present. It is not desired here to enter into any of the details of the methods by which the distinctive diagnosis of the various intracranial conditions is aided by a study of the fluid obtained by lumbar puncture, but it is essential to emphasize that not only should the fluid be studied microscopically, but that, with careful aseptic technique, cultures should be made to accurately determine the particular microorganisms present, and also that it is important in obscure cases to carry the bacterial tests still further, and as far as possible have inoculation experiments made when there exists any doubt as to the relations thus obtained and the associated aural changes. The importance of ascertaining the bacterial elements causing the meningitis, if such exists, being of the utmost value, especially in those cases of severe mastoiditis where the symptoms would seem to indicate a possible intracranial complication, and lumbar puncture shows conclusively the presence of a coincident tuberculous meningitis of low grade.

In the distinctive diagnosis of a possible brain tumor from that of a brain abscess, or extradural collection of pus limited in extent and thus circumscribed, little or no information can be obtained, and the withdrawn fluid is practically the same in both of these conditions. As a rule in such conditions, the cerebrospinal fluid remains unchanged from the normal, is clear, perfectly limpid, and contains from 0.4 to 0.8 per cent. of albumin, and if allowed to stand will not spontaneously coagulate. As long as the pus collection, irrespective of its location, remains circumscribed, and the arachnoid space is not invaded by the purulent process, practically nothing can be gained as an added diagnostic feature by lumbar puncture, but where the diagnosis from other conditions seems occult, one may gain some added negative information, as the fluid in these two conditions is frequently released under abnormally high pressure, and may also be more abundant than usual.

Between brain abscess alone and an abscess with meningitis, lumbar puncture is of great diagnostic value, as it enables one to determine the presence or absence of the latter, but at the same time, except for a possible increase of the intracranial pressure, definite information as regards the brain abscess will not be obtained. The distinctive value in these conditions is well illustrated by a case reported by Jacoby, where the diagnosis and important question of operative procedures lay between these changes, that is whether a brain abscess alone was present, or whether it was complicated with a meningitis. The puncture, however, showed pus in the cerebrospinal fluid, and operation could, therefore, not be advised; the autopsy later confirmed the correctness of this opinion, as it showed that there was an abscess of the cerebellum, and in addition a purulent meningitis was present.

Another aspect of this question will arise in those cases where the diagnosis lies between a diffuse meningitis or an abscess of the brain. Under such circumstances, lumbar puncture may be essential for the recognition of the particular condition present, and in this instance it is of the greatest service; as before shown, the meningitis may be readily recognized by this procedure, and thus a satisfactory answer will be obtained.

In the distinctive diagnosis between brain abscess and sinus phlebitis, the evidence obtained is usually negative, and lumbar puncture affords no help in distinguishing one condition from the other. In a small group of cases, however, when this condition arises and a high temperature is present, some additional information of value may be obtained by puncture, and in connection with the other symptoms will warrant one in giving a fairly definite opinion of the particular pathological changes present in the case.

It is especially with meningitis, however, that lumbar puncture presents its greatest diagnostic value, and not only may a purulent meningitis be recognized by this procedure, but so called pseudomeningitis may also be distinguished. This being well shown in a case reported by Knapp, where the radical operation was performed upon a girl of sixteen years. A few weeks following she became ill, with high temperature, delirium, vomiting, and rigidity of the cervical muscles, so that clinically the case presented all the evidences of a serious meningitis. Lumbar puncture was performed for diagnostic purposes, and while the fluid obtained was turbid, yet it was entirely free from microorganisms, so that a purulent meningitis was eliminated, and the subsequent restoration to perfect health showed the value of this procedure in such cases.

In true meningitis there is always an exudation of cells from the meninges, which produces a greater or less degree of cloudiness of the cerebrospinal fluid, so that a cloudy fluid obtained by lumbar puncture invariably predicates the presence of some degree of meningeal inflammation, and to a certain degree the extent of this turbidity is proportionate to the amount and character of the exudation. In addition to this and especially in otitic meningitis, the proportion of albumin present is of the greatest significance. To determine this, the albumin should be estimated by quantitative examination, and in meningitis one finds that this is increased from the normal ratio to 0.03 or 0.1 per cent., or even higher in some instances. When the albumin is in proportionately large amounts, such as 1.6 per cent. or more, the fluid will coagulate spontaneously, so that if one obtains a clear fluid in a case where the symptoms are suggestive of some meningeal inflammation, spontaneous coagulation is highly suggestive of an otitic meningitis, although it may possibly be of limited extent.

Where lumbar puncture demonstrates a concurrent meningitis in otitic cases it does not always indicate that surgical intervention is contraindicated, as the pathological changes may be of limited extent, and in such cases where the fluid is not markedly altered, operative measures should be proceeded with, other things being equal. Although if microrganisms are present to any degree, little can be gained by exposing the intracranial contents, a case

of Lichtheim's demonstrating this, as there was ofitis with cerebral symptoms, and lumbar puncture demonstrated the presence of streptococci, showing that a purulent meningitis was the cause of the cerebral symptoms, the correctness of this diagnosis being confirmed by autopsy.

The distinction of serous meningitis from the various intracranial complications of suppurative otitis is not materially enhanced by this procedure, as both the quantity and quality of the fluid present little or no distinctive changes in this variety, and when minor alterations are present they differ in no distinctive manner from those common to the intracranial morbid changes of otitis. The release of the fluid under increased pressure may signify increased intracranial tension, and therefore has no distinctive diagnostic value, and still further a purulent meningitis is not infrequently, in its early stages, accompanied with a serous exudate on the meninges, so that the findings at an early period

would be quite misleading.

The possibility of a tuberculous meningitis being associated with a nontuberculous mastoid suppuration may seriously render the recognition of the presence or absence of intracranial complications very difficult or practically impossible by the usual methods employed, and under such circumstances lumbar puncture is of great value in recognizing the tuberculous condition. While the finding of tubercle bacilli in the fluid is absolute proof that the meningitis is tuberculous, yet it is not always possible that these organisms will be found, and then repeated search should be made to demonstrate their presence. In some cases the cellular exudation is so small in amount that the fluid appears perfectly clear, and from its macroscopic appearances no suspicion will arise as to the serious changes in the meninges, but microscopical examination will demonstrate the organisms and render the diagnosis clear. This is shown in the cases studied by Furbringer, where tubercle bacilli were found in the fluid in twenty-seven cases, and in all the diagnosis was confirmed at autopsy, while in seven cases the exception to this was shown, as the fluid was negative, although the autopsy showed a tuberculous meningitis, thus giving a correct diagnosis in eighty per cent. of the cases.

While in general the degree of cloudiness of the fluid is to a great extent proportionate to the amount and character of the meningeal exudation, yet, as has been shown by Leutert, one may occasionally find a turbid fluid with numerous white blood cells present, and yet in such instances autopsy has showed the absence of meningitis, the condition apparently depending on the fact that at the time the puncture was made a transient and localized serous leptomeningitis was present, which resolved at a later period.

Cerebral pressure or irritation may be expressed by increased tension under which the spinal fluid escapes, and in this way lumbar puncture may be of considerable diagnostic aid when considered with other symptoms indicative especially of a cerebral or cerebellar abscess, or a localized epidural pus collection, but taken alone one cannot attach much significance to such a phenomenon.

Much importance must be attached to the nature of the abnormal cellular constituents of the fluid, in

the presence of symptoms suggestive of otitic intracranial complications and of these particular cell elements, polynuclear leucocytes predominate in purulent meningitis, so that when a turbid fluid contains a large number of these cells, with or without the presene of microorganisms, one should have little hesitation in considering the meningeal inflammation as purulent in character. When mononuclear lymphocytes predominate, or are found to the exclusion of other types, tuberculous meningitis is evidently present, especially if the fluid is clear, or but slightly clouded. Unless other symptoms indicative of this condition are also present to some degree, the lymphocytosis may be the expression of some old otitic lesion, such as a patch of chronic meningitis in relation to some carious process of the temporal bone, or it may also occur during the subsidence of an acute nonfatal otitic meningitis. The presence of red blood cells in the cerebrospinal fluid occurs in an entirely different class of otologic cases, as it bears no relation to the intracranial complications of aural suppuration, but may be mentioned here as indicative of serious traumatic injury to the labyrinth, but at the same time lumbar puncture affords little added information in such instances, as the ear symptoms alone are sufficient to make a diagnosis without subjecting the patient to this proce-

The great value, therefore, of lumbar puncture in otology presents mainly a diagnostic aspect, and the most important value is that it enables one to exclude the presence of a purulent meningitis or a tuberculosis of the meninges, and thus avoid operative procedures that would be of no benefit. Although from an otological standpoint the presence of meningeal symptoms in themselves do not contraindicate mastoid and intracranial operative procedures, unless the lumbar puncture shows that the cerebrospinal fluid is infected.

Finally, as a therapeutic application it is of no practical value at present in any of the conditions previously mentioned, except that it may possibly relieve intracranial tension in certain cases of serous meningitis. It may be briefly mentioned, however, that Gradenigo in four cases of otitic leptomeningitis employed lumbar puncture as a therapeutic agent and obtained three recoveries. In two cases the fluid withdrawn, being cloudy, contained leucocytes and staphylococci, and he believes that this procedure exerts a direct curative effect in such cases, while Thiell also believes that it is of some therapeutic value in serous and seropurulent meningitis. But the majority of otologists believe that its therapeutic usefulness is of but little moment, and, while it may be admissible in such otitic cases as are accompanied with increased brain pressure, one is not enabled to find any positive indications for its employment except for diagnostic purposes.

In labyrinthine disorders, Babinski has removed in this way from fifteen to twenty cubic centimetres of spinal fluid as a therapeutic agent, and asserts that it has a remarkable influence on the aural vertigo. He believes that it also acts favorably on the tinnitus and deafness, but not to the same extent, and alleges that it is more efficacious in pure labyrinthine lesions than in other pathological changes here. His contentions, however, have not been supported by other otologists, and Lombard and Caboche in study-

ing Babinski's method found in cases of dry adhesive otitis that there was no improvement in the hearing, although the vertigo was temporarily relieved more than the other symptoms.

SCARLATINAL EPIDEMIC FROM INFECTED MILK BOTTLES.

By Harold B. Wood, M. D., Philadelphia.

The danger of the communicability of infectious diseases when the diagnosis is difficult and the possibility of bacterial transmission at the onset of a disease is apparent to all. It may seem troublesome and drastic to institute from the very beginning of an illness disinfection of all excreta, nasal sprays, partial isolation, or protection of the water supplies, but such action will often prevent subsequent illness and death. These measures are usually considered, but another channel through which bacterial transmission occurs is too frequently neglected by the householder-the conveyance of germs to another's food supply. Whenever a case of illness of any kind appears, particularly if among children with mild or obscure symptoms, the physician besides instituting all other protective measures should particularly instruct that all milk bottles should be carefully sterilized or at least entirely filled with boiling water. Every person upon leaving the house should thoroughly cleanse the hands with hot water and soap; particularly should this be done if any food, candy, fruit, or other store is to be visited. Since all bottles discarded with the ashes are liable to be collected and used for various pur-poses all such should be broken whenever coming from an infected household.

When the diagnosis of contagion is first made the origin of the infection must be immediately traced along those lines which are open to investigation: water, ice, milk, shellfish, ice cream, butter, or other food supplies, personal playmates or associates, house surroundings, drainage, flies, and the wanderings of pet animals. All these avenues should be thoroughly inspected to discover the presence of any uncontrolled latent case or carrier. which might become a chronic disseminator. The food and milk supplies of the respective families infected with contagious disease should be reported immediately to the health officer, who should be properly clothed with authority in every municipality, however small, that he may at once commence investigation. That such action is especially necessary was shown in a recent epidemic of scarlet fever

in Collingswood, N. J.

This epidemic of scarlatina probably originated with a child whom the physician saw but once, and could make a diagnosis of only tonsillitis; it was confined to the customers of a single milkman; it was transmitted by infected bottles; and it subsided completely and immediately after investigation had led the local health officer to personally sterilize all bottles used by that milk station. During the three weeks of activity of the epidemic there developed sixteen mild and uncomplicated cases in thirteen families, there being eleven children and five adults affected, the age limits being three and

about fifty years. Every person infected used milk from the same dairy, each using raw milk for drink-

ing or cereals.

Collingswood, a rapidly growing town of some four thousand inhabitants, obtains a good water supply from the Merchantville system, which is above suspicion. The town is supplied by four or five dairies. The suspected dairy, situated in a small cemented cellar, in a village a mile distant, was supplied by two dairy farms. One farm, a half mile distant, produced seventy quarts daily; from the other about one hundred quarts were transported fifteen miles. Both barns were of the common antiquated structure, but received attention in ordinary cleanliness. No cases of disease could be located in either farm, nor at the dairy itself. The dairy was conducted by a man and his wife. All milk was brought to the dairy cellar in cans and there bottled. The bottles were merely washed with warm water, no care being taken toward sterilization. For the collection, washing, and distribution of bottles three days were required.

The epidemic supposedly originated with a little girl who on July 4th was believed to have tonsillitis. Parental denial of scarlatinal symptoms was counterbalanced by neighbors declaring they noticed desquamation of the hands and face that occurred two weeks later. On July 20th the first diagnosticated case appeared a mile distant in a boy of nine. Two days later his playmate was taken sick. After eight days two cases appeared in Collingswood involving a three year old boy and a young man. The next day a sister of the young man became ill in the same house, probably not from contact. The baby was followed by his father four days later, probably by contact. Another case appeared this same day, August 1st. The subsequent cases were: August 6th, a boy, age nine; the 7th, small boy; 9th, one boy and three girls; 10th, man, age fifty; 11th, small girl who lived with one of the girls taken ill on the 9th; 12th, another little girl. The July 4th case was probably responsible for those developing on the 20th and 22d, and these in turn transmitting by bottle to the 28th, 29th, and one August 1st case. One of these later households returning bottles daily to the dairyman undoubtedly was indirectly responsible for the succeeding nine cases. Transmission could hardly have occurred through contact or association except in three instances, the cases of July 22d, August 1st, and 11th. If this was contact transmission it occurred at the onset of the disease, and had only two or three day incubational periods. An investigation finally being made, sterilization of the dairy utensils about the thirteenth of August yielded the desired result.

In a milk epidemic an explosive onset indicates rather an infected general supply; a germ carrier in the dairy would be more apt to give an epidemic of longer duration, considering the number of infected persons, and without intervals of quiet before the early cases. The universal habit of returning to the dairy one bottle remaining in the house when the fever or rash appeared accounted for the early cases; the time in each instance giving three days for delivery of the infected bottle, and five latent days for incubation. The daily returning of infected bottles from one household accounts for the

more rapid later development of the epidemic. The results of sterilization add weight to the bottle hypothesis. Epidemics of scarlatina being transmitted through infected bottles rather than an infected supply are in the minority of those investigated, according to Trask, but three out of fifty-one epidemics being traced to this origin. In the compilation of Busey and Kober only three out of one hundred and seventy-seven scarlatinal milk epidemics were traced to bottle infection. The ratio is probably far from correct.

Such results show the necessity of at once controlling avenues of bacterial escape, the danger of permitting bottles to go from any household where illness occurs among children, the value of habitual sterilization by both householder and dairyman, and the necessity of competent sanitary officers with

legal authority.

5038 PINE STREET.

THE EFFECT OF MAMMALIAN PITUITARY ON TETANY AFTER PARATHYREOIDECTOMY AND UPON THE PUPIL.

By Isaac Ott, M. D., and John C. Scott, M. D., Easton, Pa.

Preliminary Note from the Physiological Laboratory, Medico-Chirurgical College of Philadelphia.

Pogowitsch found alterations in the pituitaries of thyreoidectomized dogs and rabbits of the nature of an increase of certain elements. Various other observers have also found changes in the pituitary in the disease of the thyreoid. Herring has shown that the posterior lobe of the pituitary furnishes a secretion which passes through the nervous portion to enter the infundibulum and ventricle of the brain. The secretion has a colloid appearance. Herring has also found definite histological changes in the pituitary body after thyreoidectomy. The most striking changes were in the nervous part of the posterior lobe, granular, hyaline, or colloid bodies becoming very numerous. Gley has shown that tetany is produced by removal of the parathyreoids, and MacAllum has confirmed this.

We performed parathyreoidectomy in several cats, which in about forty-eight hours was followed by tetany. We then injected five to ten grains of pituitary extract subcutaneously, which in the course of two hours stopped the tetany and acted as a tonic to the neuromuscular apparatus, replacing an awkward gait with trembling limbs by one of steadiness and normal movement. We also used the pituitary extract in injections by the jugular

vein with the same result.

Meltzer has shown that adrenalin dilates the pupil after removal, twenty-four hours previously, of the superiocervical ganglion. We have found in rabbits that when we excised the superior cervical ganglion on one side that after twenty-four hours' local applications of pituitary, or using it in injections into the jugular vein, or subcutaneously, a dilation of the pupil ensued. In the normal eye no effect ensued by local applications of a saturated solution.

These facts indicate a relation between the pituitary and the parathyreoids.

Correspondence.

LETTER FROM LONDON.

The General Medical Council.—The Annual Meeting of the Royal College of Surgeons.—The Feeding of Poor Out Patients.—An Interesting Legal Case.

LUNDON, December 1, 1908.

The winter session of the General Medical Council was opened last week, and this occasion is of special interest as it marks the fiftieth anniversary of its foundation. The jubilee was celebrated by a dinner at which the present members entertained their predecessors in office, and the president, Sir Donald Macalister, was in the chair. The General Medical Council was founded in 1858 with the object of enabling persons requiring medical aid to distinguish qualified from unqualified practitioners. Its function was to safeguard the public by insuring that the Register should be trustworthy. end the Council was intrusted with twofold powers. It had authority to supervise the admission tests whereby the "qualification" of practitioners was ascertained, and it had authority to remove from the Register those who after qualification had proved themselves unworthy. From these two powers the manifold activities of the Council as they are exercised to-day have slowly but inevitably been developed. It had at first to contend with grave difficulties, internal and external, and its judicial functions were often challenged and had to be sustained in the general courts of law. The decisions of the courts have declared the nature and extent of its jurisdiction and have upheld its judgments when they were contested. It has now developed into a body of some power and has done much to increase the prestige of medicine. The criticism and cooperation of the various licensing bodies have enabled it to formulate a standard of "qualification" which is generally accepted, not only within the United Kingdom, but in many other parts of the British Empire.

The president in his address mentioned some of the work the Council was undertaking relating to unqualified practice. By the assistance of the Colonial and Foreign Offices a large mass of authoritative information had been obtained respecting the laws regulating the conditions of obtaining medical and other degrees and the restrictions imposed on unqualified practitioners throughout the Empire and in foreign countries. This information, which reached the Council's office in various forms and in numerous languages, has been carefully analyzed and digested by the registrar and his staff for the use of the Committee on the Prevention of Unqualified Practice. As it is entirely derived from official sources, the digest will be of value to the public, and when it has served the immediate purpose of the committee it will be issued as one of the Coun-

cil's publications.

The annual meeting of the fellows and members of the Royal College of Surgeons of England was held at the college on November 19th. Mr. Henry Morris, the president, was in the chair and fifteen other members of the Council were present. The meeting was much larger than usual. The president was asked if any steps were being taken in

reference to the proposed cooperation between the two Royal Colleges and the University of London. In reply the president said that negotiations were proceeding and that if they arrived at any arrangement the future holders of the diplomas of M. R. C. S. and L. R. C. P. would also have the degrees of M. B. and B. S., but the arrangement would not be retrospective. Mr. Joseph Smith then moved the first resolution, "That this meeting thanks the Council for having for the first time in its history taken a poll of the members of the College, but regrets that the Council found itself unable to abide by the result." The poll referred to by Mr. Smith was with reference to the admission of women. The result of the poll showed a majority against their admission, but in spite of that the Council decided to admit them. This resolution was seconded by Dr. Sidney C. Lawrence and was carried. After other resolutions had been passed, the president stated that, with regard to the admission of general practitioners to the Council, at the last election a fellow of the college in general practice was a candidate and received a large measure of support.

The governors of the Westminster Hospital have. owing to the munificence of Lady Campbell Clarke, been enabled to make a practically new departure in hospital administration. It is the unfortunate experience of the physicians and surgeons who work in our large London hospitals that too many of the out patients stand in need, not only of medical treatment, but of extra food, which many of them are by reason of limited means unable to provide for themselves. It is to meet this difficulty that the Lady Campbell Clarke Fund has been formed by her at the Westminister Hospital. The object of the fund is to provide food in such necessitous cases under the direction of the visiting staff. The meals are to be given in the hospital itself, but provision is made which will enable such things as milk to be taken away for the benefit of children and others who may require it frequently. There is no doubt that such a fund is badly needed in London and

will fill a decided want.

An interesting case came before the courts last week. Action was brought by Dr. A. E. Neale against the Bartitsu Light Cure Institute (Limited) to recover damages for breach of contract to employ the plaintiff as consulting medical superintendent of the institute. The company had agreed to employ the plaintiff on terms approved by the Ethical Committee of the British Medical Association. He now alleged that the defendants had rendered it impossible for him to fulfil his agreement with them by reason of their breach of these provisions. The defendants denied this and counterclaimed for damages for breach on the plaintiff's part of the agreement caused by his alleged incompetence and want of skill. To this the plaintiff replied that, if any injury had been caused by his treatment of certain diseases, it arose from the impossibility of curing such diseases with the defendant's machinery and appliances. It was proved that the institute had caused a large number of pamphlets to be printed and distributed advertising the institute, and that this was done without the consent or knowledge of Dr. Neale. Dr. George Bateman, secretary of the Medical Defense Union, one of the witnesses. stated that the contents of the pamphlet in question were such that if it had been issued with Dr. Neale's consent he would have rendered himself liable to removal from the *Medical Register*. The result of the case was that Dr. Neale was awarded £600 damages. It comes rather as a surprise that the Ethical Committee of the British Medical Association should under any circumstances allow a medical man to associate himself with such an institute.

Therapeutical Aotes.

Marginal Blepharitis.—This affliction, which is characterized by redness of the edge of the lids of the eyes and the formation of crusts or scales at the roots of the lashes, and usually affects young children at school, is commonly associated with a slight degree of myopic astigmatism, which makes it essential that the refraction should be tested, and proper glasses ordered, if necessary. In mild cases, according to The Hospital for November 14, 1908, the glasses alone are almost sufficient to insure a cure, but if there is much redness and incrustation of the edges of the lids it is advisable to wash these crusts off with a warm alkaline borated lotion. The following formula is the most usual:

| \mathbf{R} | Sodium bica | arbonat | e, | | | | | | ٠ | .gr. | V11 |
|--------------|--------------|----------|----|------|------|------|------|--|---|----------|-----|
| | Sodium bor | ate, | | | | | | | | .gr. | VII |
| | Sodium chlo | oride, . | | | | | | | | .gr. | VII |
| | Refined sug | | | | | | | | | | |
| | Water, | | | | | | | | | | 311 |
| M. | Ft. solutio. | | | | | | | | | | |

As alternatives to the foregoing prescription ointments may be ordered as follows:

| ment | s may be ordered as follows. |
|--------------|------------------------------|
| \mathbf{R} | Ammoniated mercury,gr. ss; |
| | Lead acetate,gr. xlv; |
| | Expressed oil of almond, |
| | Petrolatum,3x. |
| M. | |
| P, | Salicylic acid, gr. xv; |
| | Zinc oxide |
| | Pulverized starch, |
| | White petrolatum,3v. |
| 7.7 | , |

The author of the article cited reiterates the necessity of first correcting any error of refraction that may be found. Without this precaution other treatment is "merely ploughing the sand."

For Fissures of the Tongue.—The application to the surface of the fissures of the following solution by means of a camel's hair pencil is recommended in Annales de thérapeutique dermatologique et syphilioraphique:

| | 1 | | | | | |
|-----|-----------|------------|----------|------|---------|----|
| R | Carbolic | acid, crys | stals, . | | gr. xl | ; |
| | Tincture | of iodine | , | | | |
| | Glycerin, | | | | āā 3iii | i. |
| 3.1 | | | | | | |

The Treatment of Acne.—The general treatment should consist, according to Jeanselme (Bulletin général thérapeutique, November 8th, 1908), of the administration of laxatives, charcoal, and magnesia. Intestinal antiseptics should not be used. The food should be simple, sauces and condiments being interdicted. Fruits and vegetables should be partaken of freely as well as pure water and weak tea. The fat of pork, eggs, sea fish, canned foods, fermented cheeses, etc., should be avoided. Lymphatic

patients should bathe freely and be treated with arsenic and codliver oil. Anæmic patients should be treated with preparations of iron and arthritic patients with alkalies.

Every evening an ointment should be applied consisting of a mixture of eighty parts of cold cream with from one to three parts of precipitated sulphur, or gauze moistened with the following lotion may be applied:

| | piica. | | | | | | | | | | | | | | |
|---------|-----------|-----|-----|-----|----|------|------|------|------|--|------|------|----|--------|--|
| P_{i} | Precipita | ted | sul | phy | ٢, | | | | | | 31 | to | n. | 3iv | |
| | Glycerin, | | | | | | | | | | | | .3 | Siiss | |
| | Spirit of | 731 | nph | or. | | | | | | | | | | 3i | |
| | Water, | | | 4 | ٠. | | | | | | | | | . žiss | |

This should be washed off with hot water the following morning.

An ichthyol ointment containing from five to ten per cent. of ichthyol may be used.

If the local application of sulphur causes excessive irritation, the following ointment may be applied alternately with the sulphur cream:

| R | Zine oxide, | | | | | | | | | | | , | | | |
|------|-------------|--|------|--|--|--|--|--|--|--|--|-----|--|---------|--------|
| | Talc, | | | | | | | | | | | . } | | .āā | 3iiss. |
| | Petrolatum, | | | | | | | | | | | -) | | | |
| TAT. | | | | | | | | | | | | | | | |

In acne punctata the comedones are expressed and the surface is thoroughly washed with either Castile or green soap, taking proper precautions in the latter case to prevent undue irritation. In pustular acne a teaspoonful of yeast is given before each meal and the face steamed with boiling water for five minutes morning and evening. If this treatment fails the pustules may be opened with a fine galvanocautery, or with a scarificator. Hypertrophic acne should be treated surgically, the diseased tissues being removed. The results of the treatment of keloid acne are always uncertain. Scarification is sometimes helpful, but if the improvement is very slow it should be discontinued. The keloids are sometimes absorbed spontaneously, if not irritated. The simple zinc oxide plaster sometimes proves effective.

For the Pain of Uterine Cancer.—Lutaud prescribes the following:

| | O . | |
|---------|---|-----|
| P_{i} | Tincture of thuja, | |
| | Solution of potassium arsenite, | 3; |
| | Syrup of acacia, | |
| | Water, | ii. |
| M. | et Sig.: One teaspoonful thrice daily before meals. | |

The Local Treatment of Coccygodynia.—The local medical treatment of the painful affection of the coccyx and the surrounding parts which is termed coccygodynia, and which is a symptom almost peculiar to women, consists, according to *The Practitioner* for December, 1908, in the application of ointments, suppositories, blisters, cauterization, or electricity. It is observed that a sedative ointment rubbed into the skin of the coccygeal region sometimes gives relief. The following ointment is said to be efficacious:

| $\mathbf{P}_{\!\scriptscriptstyle E}$ | Tincture of | aconite, . | ٠. | | | | | | | | . 3 | is: | ; ; |
|---------------------------------------|-------------|------------|----|--|------|------|--|--|--|--|-----|-----|-----|
| | Belladonna | omtment, | | | | | | | | | | | i. |

M. ft. unguentum.

The application of the actual cautery is said to constitute the most certain remedy. A Paquelin cautery is used to cauterize the skin over the sacral foramina on each side the skin being burnt deeply, and the resulting eschar is then treated as an ordinary granulating wound.

NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal and The Medical News.

Entered at the Post Office at New York and admitted for trans-portation through the mail as second class matter.

NEW YORK, SATURDAY, DECEMBER 19, 1908.

ANAPHYLAXIS.

A Harvey lecture was delivered by Dr. M. J. Rosenau on Saturday evening, December 5th, on a subject with which his name has been intimately associated, namely, anaphylaxis. Those who were present heard, not a long, wearisome recital of laboratory experiments or of opposing theories, but a concise exposition of our present knowledge of anaphylaxis. supersusceptibility, supersensitiveness, or Allergie, as the condition has variously been

With the vast amount of scientific research done on the various phases of immunity during the past twenty-five years, it is strange that the phenomenon which is now known by these terms should have escaped attention. It is true, the rashes sometimes produced by injections of diphtheria antitoxine have been studied, but their cause has generally been believed to be some toxic substance, probably a globu-The reason for the long period of incubation has not been understood. Practically all of our present knowledge of this subject has been gained in the past three or four years. The term anaphylaxis was introduced by Richet, who intended to express by it a condition the opposite of prophylaxis. Working with the poison of the sea anemone, he found that when dogs were injected with this poison the first injection produced such changes in the dog's organism that a much smaller subsequent dose produced rapidly fatal symptoms. He found that this

result was only produced if at least a certain interval had elapsed between the two injections.

It has since been found that the condition is in no sense anaphylaxis, but is merely a quickened response on the part of the body so injected. Von Pirquet therefore prefers to use the term Allergie (altered energy), and this is the term in common use in Germany. The condition is very well illustated by what takes place in vaccination. an individual is vaccinated for the first time, the well known vesicle surrounded by the inflammatory areola appears after a distinct period of incubation. When a vaccinated individual is revaccinated, there appears to be no response whatever, but careful observation will show that this is not the case. There is a response, but the changes occur so rapidly after the revaccination that they usually pass unnoticednot anaphylaxis, therefore, but Allergie,

When, in 1906, Rosenau and Anderson published their well known study on the Cause of Sudden Death Following the Injection of Horse Serum, few realized that this should mark a most important contribution to our conceptions of immunity. These authors found that guinea pigs which had once been injected with a small dose of horse serum were liable to an acute fatal poisoning when again injected with horse serum some time later. The original injection, it was found, could be as small as a millionth of a cubic centimetre. The interval between the injections was very important, not less than about ten to twelve days being necessary.

While he was visiting this country, in 1903, Ehrlich's attention was drawn by Theobald Smith to the fact that the guinea pigs which had been used for testing toxine-antitoxine mixtures were exceedingly susceptible to subsequent injections of horse serum, the second injection often proving fatal. Returning to Frankfort, Ehrlich gave this problem to his pupil Otto, who, almost simultaneously with the American investigators, published a paper containing conclusions entirely in accord with those of Rosenau and Anderson. Otto therefore speaks of the "Theobald Smith phenomenon."

It is gratifying that most of the important contributions concerning anaphylaxis have come from this country. Shortly after Rosenau's publication a masterly article appeared by Gay and Southard, and these authors were the first to describe pathological lesions occurring as a result of the intoxication. According to Gay and Southard, horse serum contains a substance which they term "anaphylactin," which acts as an irritant to the bodily cells. As a result of the irritation, after some days, the cells are in such a condition that a second injection of horse serum may easily produce fatal results. Subsequent investigations showed that this action was not confined to horse serum, but that the condition was apparently a fundamental fact in almost all kinds of immunity. Rosenau and Anderson, in particular, showed that an animal could be sensitized to three different proteids at the same time, and would then be in a condition to react to a subsequent injection of each of these.

There is still some question whether the substance which sensitizes the animals is the same as that which subsequently poisons them. Most observers think that different substances are involved. though Rosenau and Anderson believe that the substances are identical. The latter observers also noted the interesting fact that animals could be sensitized by feeding them with the proteid. Thus, guinea pigs were fed with raw beef and thus sensitized to a subsequent injection of ox serum. meat must be given raw, as cooking destroys the sensitizing substance. In view of this fact, one might expect that in countries where raw horse meat is consumed (smoked sausage or raw chopped horse meat) serum accidents would be more frequent in connection with the use of diphtheria antitoxine. So far as is known, however, this is not the case, though it is not easy to gather statistics on the subject. It is not certain that man is sensitized in the same way as guinea pigs. It is well known that a number of sera, such as the antistreptococcus sera and the antituberculous serum of Maragliano, are constantly being administered in repeated injections, and thus far no such conditions of anaphylaxis have been observed. In this connection, it is well to remember that the interval between the injections, as well as the size of the dose, is highly important in producing the conditions in animals.

The investigations in anaphylaxis are perhaps destined to play an important part in a number of other directions. Thus, it is possible that some light may be thrown on a number of obscure disorders, such as eclampsia and epilepsy. Furthermore, a considerable change has already been effected in our views concerning endotoxines. It is well known that in the absence of demonstrable extracellular toxines, we have assumed that certain bacteria, such as typhoid, cholera, meningococcus, etc., must needs possess toxines closely bound up with their protoplasm, i. e., endotoxines. Now that we know that a harmless proteid can sensitize the bodily cells to a subsequent injection with the same proteid, leading to severe symptoms of intoxication and death, we no longer need to assume the existence of these endotoxines. Rosenau and Anderson found that this supersensitiveness could be transmitted from parent to young, though only through the maternal side. The male parent does not transmit this quality.

Rosenau suggests that there may perhaps be a transmitted supersensitiveness to tubercle bacillus substance in the cases in which tuberculous disease is said to run in families. Certainly all who have investigated the subject admit that environment will not explain all the instances of family tuberculous disease.

In connection with the use of antitoxine, it is interesting to note that the cases of sudden death following the administration of serum have several times been in asthmatic individuals. Just what their peculiar susceptibility is due to is not known, but the point is well worth remembering. The same is true of persons who have ill defined feelings of distress when in the vicinity of horses.

These investigations have also modified our views concerning the nature of the period of incubation. In most of the infectious diseases it has been assumed that the period of incubation represents the time necessary for the virus to increase sufficiently to be able to produce symptoms. Ehrlich long ago showed that toxines also produced their symptoms only after a period of incubation, and yet a multiplication of the virus was out of the question. In view of what has been said, it will be seen that the views of Gay and Southard furnish an adequate explanation of the incubation period, even of poisonings by proteids that are not poisonous.

THE TARIFF ON SCIENTIFIC BOOKS AND INSTRUMENTS.

In regard to a revision of the tariff, the average man understands by that term a lowering of duties. Already, however, there is a rumor that certain interests are endeavoring to have a duty placed on foreign medical books and to have this duty payable by libraries and other institutions as well as by individuals. At present medical books printed in languages other than English may be imported free of duty. Books printed in English, however, may be imported only upon the payment of a duty of twenty-five per cent., but libraries may import such books free of duty. Scientific instruments also may be imported only upon the payment of a duty of from forty-five to sixty per cent. ad valorem. Scientific men as a rule pursue their studies largely for the purpose of contributing to the sum of the world's knowledge and for the purpose of improving the conditions under which the individual lives. They are not generally ambitious for a large return for their very important contributions to the advancement of civilization. We have a right to expect that the government will assist these men in the performance of their work by placing the instruments and books necessary for their use ready to their hands at the lowest possible figure. We should like to see the duty removed from scientific books printed in the English language, to see the duty left off scientific books published in foreign languages, and to see the duty removed from scientific instruments. In order that there shall be no ambiguity about the meaning of the schedule, we should like to see the words "medical and surgical" added to the word "scientific" as applied to books and instruments. Medical, surgical, and scientific books and instruments should, in our opinion, be admitted to this country absolutely free of duty.

At the December meeting of the College of Physicians of Philadelphia, the matter was brought up by Dr. W. W. Keen, and a resolution was adopted authorizing the president of the college to appoint a committee to prepare a suitable resolution or resolutions opposing the proposed abolition of the present exemption from duty of books in other languages than English, and the abolition of the exemption of libraries from the payment of duty on imported books. We should advise other medical, surgical, and scientific societies to adopt similar methods, so that the members of the Congress of the United States may know in unmistakable terms that scientific opinion is unanimously opposed to increasing the duties upon these articles.

A PROPOSED MEDICAL RESERVE CORPS OF THE NAVY.

The Bureau of Medicine and Surgery of the Navy Department has not been slow in perceiving the advantages of the new Army Medical Reserve Corps. In his last annual report, for the fiscal year 1908, Surgeon General Rixey remarks that it is hoped that the naval militia bill may receive the favorable consideration of the Sixtieth Congress during its second session, and he adds that "it is the intention of the bureau to submit to the department for approval the draft of a bill providing for a reserve corps." There ought to be no doubt, we should say, of the favorable action of Congress with regard to such a bill, for certainly the navy as well as the army always finds itself in pressing need of additional medical officers whenever the immediate prospect of hostilities arises.

So far as we can see, no mistakes have been made in the organization of the Army Medical Reserve Corps, so that there is no error to deter the naval Bureau of Medicine and Surgery from organizing its proposed reserve corps on the principles that have been followed in the army, regard being had, of course, to the peculiarities of the naval medical service. As at present constituted, the Bureau of

Medicine and Surgery of the navy is remarkably efficient, and we may be sure that any bill framed by it will be thoroughly entitled to enactment by Congress.

THE ACTING ASSISTANT SURGEONS OF THE NAVY.

The present acting assistant surgeons of the navy are not on the footing of the old contract surgeons of the civil war. They are appointed officers, and their appointment is dependent upon their passing a physical and professional examination satisfactorily. This has been the case for the last ten years. The examining boards, consisting of medical officers of the navy, are in practically continuous session at New York, Philadelphia, Washington, Chelsea, Mass., and Mare Island, Cal. Consequently, as Surgeon General Rixey states in his last annual report, for the fiscal year ending June 30, 1908, "no candidate is discouraged nor likely recruits sacrificed by deferred examination."

On the recommendation of the Bureau of Medecine and Surgery, the Secretary of the Navy issued a notable order on October 8th of this year. The order cancels the permits for examination of those candidates for appointment as assistant surgeon who had not reported for examination, and provides that "hereafter candidates for admission to the Medical Corps of the United States Navy will be examined only for and will enter as acting assistant surgeons, and on the 1st day of October following they will be ordered to the Naval Medical School for a period of six months' instruction. At the expiration of this tour of duty the whole class will be examined for the position of assistant surgeon." Thus, it will be seen, provision is made for a very desirable probationary service, and, since conditions so favorable for candidates have been established, the bureau is abundantly warranted in its intention of requiring from successful candidates a contract to serve for a certain length of time.

H. EMORRHOIDS IN CHILDREN.

A curious example of the disagreement of experienced men concerning a very simple matter of observation is afforded in an article by Dr. Denis G. Zesas, published in the Archives générales de chirurgie for October 25th. It was in 1873, in the Gazette des hôpitaux, says Zesas, that Lannelongue asked the question, Do children have hæmorrhoids? Bouchut replied that hæmorrhoids did not exist in children, and that any diagnosis of them in childhood was erroneous. Gosselin was of the same opinion, and he said: "Whenever children said to

have hæmorrhoids have been brought to me, I have found nothing but a rectal polypus." Giraldès, however, wrote as follows: "Hæmorrhoids, very rare in the child, form bluish tumors due to dilatation of the veins, and are readily to be seen if we separate the folds of the verge of the anus." Jobert de Lamballe and Dupuytren were more uncertain, the former declaring that hæmorrhoids were so rare in children that some authors denied their existence. Lancereaux called them exceptional, and Curling rare. Other authors are cited to the same effect.

On the other hand, a writer called "Ernka" in the text and "Truka" in the bibliography (neither of which names we find in the Index Catalogue) is said to have reported thirty-nine cases, and Potain, speaking of the heredity of hæmorrhoids, relates the case of two children of the same parents who were born with hæmorrhoids. Henoch is cited as having met with only three cases in his long career, in children aged three, six and seven years respectively, and Houzel as having found but four instances among about 500 children examined, though he speaks of a "hæmorrhoidal state" which he regards as likely to end in the formation of true hæmorrhoids. Reinbach is inclined to believe that hæmorrhoids would oftener be found in children if the region of the anus was more frequently examined.

THE SERUM TREATMENT OF HAEMO-PHILIA.

In our issue for December 12th, on page 1137, we commented on a recent article by Dr. Dejardin, of Liège, from which it appeared that injections of normal serum were efficacious in the treatment of hæmophilia. Dr. F. L. Wachenheim, of New York, has been kind enough to call our attention to an article of his, entitled The Hæmorrhagic Diseases and their Allies in the Light of Modern Pathology, that appeared in the Medical News for January 16, 1904. Dr. Wachenheim thinks that this article of his anticipated Weil and others in the matter of the treatment of hœmophilia with "any serum."

Dbituary.

JOHN T. WHEELER, M. D., of Chatham, N. Y.

Dr. Wheeler died after a brief illness, from pneutionia, on December 3d. He was in the prime of life at the age of fifty-eight. His life had been exceedingly useful. In his profession he was a leading man of his part of the State. In his community he was, moreover, a citizen of public spirit, and in educational work especially was instrumental in establishing a village school and public library of high

character, while in varied ways his loss to the public will be felt. In public health his interest culminated more recently in his being placed in charge of the Division of Communicable Diseases of the State Department of Health. In his professional work he was always ready to bear his part and filled the position of president of the third district branch of the State medical society when it was first organized, and had this year been vice-president of the State society. He was a gifted writer and wrote with clearness and elegance. He had a pleasing presence, a winning manner, and a good heart. On the day of his funeral all business places were closed and there was a large gathering of saddened friends to pay the last tribute.

JOHN SUTHERLAND, M. D., of Bedeque, P. E. I.

On the morning of October 5th Dr. Sutherland was found dead in his bed in Montreal, where he was making a short stay on his return from a visit to Chicago. Up to that time he had appeared to be in good health. He was a native of Stanley Bridge, P. E. I., and was sixty-two years old. He was a graduate of the Medical Department of the University of Pennsylvania, of the class of 1876, and had been a successful practitioner in Bedeque for more than thirty years.

Hews Items.

Changes of Address.—Dr. Paul Bartholow, to 23 West Thirty-sixth Street, New York.

The Toronto Free Hospital for Consumptives.—Subscriptions to the H. C. Hammond Endowment Fund for this hospital so far received amount to \$41,740.

The Society of Physicians of Canandaigua, N. Y., held a meeting on Thursday, December 10th. The paper of the evening was read by Dr. D. A. Eiseline on Status Lymphaticus.

"Tag Day" in San Francisco,—A tag day was held recently in San Francisco, which added \$28,000 to the Children's Hospital Fund. Of this amount \$12,000 was collected by school children.

The Philadelphia County Medical Society's committee on public policy and legislation consists of the following members: Dr. James B. Walker, Dr. L. Webster Fox, Dr. William S. Higbee, Dr. James M. Anders, and Dr. John Ruoff.

The New York Academy of Medicine.—A meeting of the Section in Obstetrics and Gynacology will be held on Thursday evening, December 24th. After the presentation of specimens by Dr. L. J. Ladinski and Dr. Leonard S. Rau, Dr. J. Van Doren Young will read a paper entitled A New Operation for the Correction of Retrodeviation of the Uterus.

The Buffalo Association for the Relief and Control of Tuberculosis is the name of a society formed in Buffalo recently. At a meeting of prominent men and women who are interested in the establishment of a hospital for consumptives, at which Dr. Matthew D. Mann presided, a committee of fifteen was appointed to effect permanent organization.

The Buffalo, N. Y., Academy of Medicine.—A meeting of the Section in Obstetrics and Gynacology was field on Tuesday evening. December 15th. The programme included two papers, one entitled Manual Dilatation of the Parturient Canal, by Dr. P. W. Van Peyma, and the other entitled Education of Women Relative to Diseases Incident to the Menopause, by Dr. De Witt G. Wilcox.

The Medical Society of the County of Kings, N. Y.— The mnety-second regular meeting of the Section in Padiatrics was held on Friday evening, December 18th. The principal feature of the scientific programme was a paper entitled The Care of the Rheumatic Child, by Dr. Le Grand Kerr.

The Northern Medical Association of Philadelphia held a stated meeting on Friday evening, December 11th. Dr. David Reisman read a paper on the Ætiology and Pathology of Cirrhosis of the Liver. Dr. Judson Daland read a paper on Symptomatology and Treatment of Cirrhosis of the Liver.

The Philadelphia Academy of Surgery held a stated meeting on Monday evening, December 7th. Dr. Gordon J. Saxon gave a demonstration of an apparatus for the continuous administration of saline by the rectum. The remainder of the programme consisted of the presentation of patients and the reports of cases.

Contagious Diseases in Chicago.—During the week ending December 5, 1908, there were reported to the Department of Health 778 cases of contagious diseases, as follows: Diphtheria, 192 cases; scarlet fever, 183 cases; measles, 102 cases; chickenpox, 93 cases; whooping cough, 9 cases; pneumonia, 28 cases; tuberculosis, 93 cases; typhoid fever, 52 cases.

The Society of Medical Jurisprudence, New York, held its two hundred and seventeenth regular meeting on Monday evening, December 14th, Officers for the ensuing year were elected as follows: President, Dr. Robert A. Murray; vice-president, Mr. Alfred E. Ommen; treasurer, Mr. John C. West; recording secretary, Mr. Charles P. Blaney; corresponding secretary, Mr. John S. Durand.

The Rochester, N. Y., Academy of Medicine.—The regular monthly meeting of Section III (Obstetrics, Gynacology, and Padiatrics) was held on Wednesday evening, December 16th. Cæsarean section was the topic selected for consideration. Dr. William M. Brown presented reports of interesting cases, and Dr. Edward W. Mulligan opened the general discussion.

The Medical Society of the County of Chautauqua, N. Y., held its annual meeting in Jamestown, N. Y., on December 9th, and elected the following officers for the ensuing year: President, Dr. Morris N. Bemus, of Jamestown; first vice-president, Dr. Edgar Rood, of Westfield; second vice-president, Dr. E. A. Scofield, of Bemus Point; secretary and treasurer, Dr. H. A. Eastman, of Jamestown. The Philadelphia Neurological Society held a meet-

The Philadelphia Neurological Society held a meeting on Friday evening, December 18th. After the exhibition of a number of patients, the following papers were read: Association and Reinforcement in Aphasia, by Dr. F. X. Dercum; Encephalitis, by Dr. S. D. Ingham; Tumors of the Lateral and Third Ventricles, by Dr. T. H. Weisenburg and Dr. W. F. Guilfoyle; Disease of the Optic Nerve as the Earliest Symptom of Multiple Sclerosis, by Dr. Alfred Gordon.

Medals Awarded by the Royal Society.—Announcement is made that the president and council of the Royal Society have awarded medals for 1008 as follows: The Copley medal to Dr. Alfred Russel Wallace; the Rumford medal to Professor H. A. Lorentz; Royal medals to Professor John Milne and Dr. Henry Head; the Davy medal to Professor W. A. Tilden; the Darwin medal to Professor August Weissman; and the Hughes medal to Professor Eugen Goldstein.

The Section in Otology and Laryngology of the College of Physicians of Philadelphia met on Wednesday evening, December 16th. Dr. Walter Roberts reported a case of temperosphenoidal abscess, and presented the patient. Dr. S. Mac Cuen Smith made a few remarks on mastoid pain. Dr. Joseph S. Gibb read a paper on the treatment of recurring attacks of lacunar tonsilitis, and described the method of removing submerged tonsils by dissection and snare.

Officers of the Richmond, Va., Academy of Medicine and Surgery.—At the monthly meeting of the Academy, which was held on the evening of December 8th, the following officers were elected to serve for the ensuing year: President, Dr. McGuire Newton; first vice-president, Dr. Marvin E. Nuckols; second vice-president, Dr. Manfred Eall, Jr.; third vice-president, Dr. Allen Freeman; secretary, Dr. Wark W. Peyser, reelected; assistant secretary, Dr. W. Brownley Foster; librarian, Dr. G. Paul La Roque; treasurer, Dr. W. A. Sheppard.

The Norwegian Hospital Alumni Association, Brooklyn, held its ninety-ninth regular meeting on December oth, at the residence of Dr. Arthur Longstreet. Dr. Robert E. Coughlin was elected president; Dr. John H. Ohly, vice-president; and Dr. Louis Stork, secretary and treasurer. The one hundredth meeting of the association, which will be held in January at the home of Dr. Sewell Matheson, will be celebrated in a manner fitting to the occasion.

Charity Ball Beneficiaries.—The Philadelphia Charity Ball will be held on January 27th, in the Academy of Music, Philadelphia. The beneficiaries selected by the committee having the ball in charge are the Children's Orthopædic Ward of the Hospital of the University of Pennsylvania, the Children's Ward of the Jefferson Hospital, the Kensington Hospital for Women, and St. Christopher's Hospital. The German American Charity Ball will be held in the Academy of Music, Philadephia, on Monday evening, February 18th. The beneficiaries are the Rush Hospital for Consumptives and the Samaritan Hospital.

Scientific Society Meetings in Philadelphia for the Week Ending December 26, 1908:

Monday, December 21st.—Medical Jurisprudence Society; Medical Society of the Woman's Hospital; Ornithological Section, Academy of Natural Sciences.

Wednesday, December 23d.—Philadelphia County Medical Society.

THURSDAY, December 24th.—Pathological Society; American Entomological Society and the Entomological Section, Academy of Natural Sciences; Section Meeting, Franklin Institute; Philadelphia Botanical Club.

Alumni Association of the New York Skin and Cancer Hospital.—At a meeting of this association, which was held on Wednesday evening, December 16th, under the presidency of Dr. H. H. Whitehouse, the following papers were read: Lupus and Epitheliomata, their Treatment by Excision and Paste, by Dr. B. Merrill Ricketts, of Cincinnati; Influence of Gravity on Lesions of the Skin, by Dr. R. M. Vermilye; The Practical Physician versus the Para Pathologist, by Dr. J. Francis Airken; The Conjunctival Tuberculin Reaction in Certain Diseases of the Skin, by Dr. Jerome Kingsbury; Anæsthesia for Plastic Operations on the Face, by Dr. James T. Gwathmey.

The American Physiological Society will hold its twenty-first annual meeting in Baltimore during convocation week, beginning December 20, 1908. Joint sessions will be held with the American Society of Biological Chemists, with the Section in Physiology and Experimental Medicine of the American Association for the Advancement of Science, the Society of American Bacteriologists, and the Association of American Anatomists. According to the preliminary programme, which has just been received, the meeting promises to be one of great interest and value. Further information regarding the meeting may be obtained from the secretary of the society, Dr. Reid Hunt, Twenty-fifth and E Streets, N. W., Washington, D. C.

The Hospital Ship Relief Declared Unseaworthy.—
The hospital ship Relief, which suffered so severely in the typhoon on its way to Manila, has been declared unseaworthy, and will be used as a floating hospital somewhere in the Philippines, probably at Olongapo. The Solace will be fitted out for active service at the Brooklyn Navy Yard, and assigned to duty with the Atlantic fleet when that fleet arrives in home waters in February. It will probably accompany the fleet to the Cuban drill grounds. It is reported that the Surgeon General of the Navy will recommend the construction of two additional hospital ships, to cost \$1,000,000 each. The need for these ships was referred to in President Roosevelt's message to Congress.

The Southside Virginia Medical Association.—The twenty-third meeting of this association, which was held in Emporia, Va., on Tuesday, December 8th, was one of the most successful in the history of the organization. The attendance was large and the programme unusually good. Officers for the ensuing year were elected as follows: Dr. C. W. Astrop, of Surry, president; Dr. T. M. Raines, of Wakefield, first vice-president; Dr. E. M. Parker, of Emporia, second vice-president; Dr. R. H. Sims, of Powellton, fourth vice-president; Dr. O. C. Wright, of Jarratt, treasurer; and Dr. E. F. Reese, of Courtland, secretary. The next meeting of the association will be held in Petersburg in March, 1909.

The Medical Association of the Greater City of New York.—A stated meeting of the association will be held in Du Bois Hall, New York Academy of Medicine, on Monday evening, December 21st, at 8:30 p. m. Dr. John B. Deaver, of Philadelphia, will read a paper on Gastric Neuroses. Dr. Anthony Bassler will read a paper entitled Indications for Surgery in Gastric Disease. Among those who will participate in the general discussion are Dr. Robert F. Weir, Dr. George E. Brewer, Dr. Joseph B. Bissell, Dr. Max Einhorn, Dr. Robert Coleman Kemp, and Dr.

The Mortality of Chicago.—During the week ending December 5, 1908, there were reported to the Department of Health of the City of Chicago 520 deaths from all causes, as compared with 520 for the preceding week and 546 for the corresponding period in 1907. Of the total number of deaths 142 were of children under five years of age. The principal causes of death were: Apoplexy, 5 deaths; Bright's disease, 41 deaths; bronchitis, 7 deaths; consumption, 49 deaths; cancer, 23 deaths; diphtheria, 20 deaths; heart diseases, 57 deaths; measles, 2 deaths; intestinal diseases, acute, 38 deaths; measles, 2 deaths; nervous diseases, 20 deaths; pneumonia, 87 deaths; scarlet fever, 9 deaths; suicide, 4 deaths; typhoid fever, 6 deaths; violence (other than suicide), 25 deaths; whooping cough, 1 death; all other causes, 124 deaths.

The Tri-Professional Medical Society of New York held a stated meeting at the Hotel Astor on Tuesday evening, December 15th. Interesting cases and specimens were presented by Dr. J. M. Rector, Dr. J. Monroe Lieberman, and Dr. Augustin H. Goelet. Dr. Edward D. Franklin read a paper entitled Reproduction Shortens Life, which was discussed by Dr. B. S. Talmey, Dr. W. J. Lederer, and Dr. Augustin H. Goelet. Dr. Harold D. Corbusier read a paper on Some Effects of the Sun upon the Body, and the discussion which followed was opened by Dr. G. Morgan Muren, Dr. J. Monroe Lieberman, and Dr. J. Carlisle De Vries.

Vital Statistics of New York.—During the week ending December 5, 1908, there were reported to the Department of Health of the City of New York 1,213 deaths from
all causes, as compared with 1,430 for the corresponding
period in 1907. The annual death rate in 1,000 population
was 14,31 in the whole city, and in each of the five boroughs it was as follows: Manhattan, 13,65; The Bronx,
15,61; Brooklyn, 14,68; Queens, 13,68; and Richmond, 23,13.
The total number of deaths of children under five years of
age was 309, and of these 208 were under one year of age.
There were 87 violent deaths, of which 23 were due to suicide, 7 to homicide, and 57 to other accidents. There were
121 still births. Eight hundred and ninety-eight marriages
and 2,465 births were reported during the week.

An Opening for a Woman Physician in the Government Service.—The United States Civil Service Commission announces that an examination will be held on January 13, 1909, to secure eligibles from which to make certification to fill a vacancy in the position of medical interne (female) in the Government Hospital for the Insane, Washington, D. C., at a salary of \$500 per annum, with maintenance. The commission has experienced considerable difficulty in filling this vacancy, and properly qualified persons are urged to enter this examination. Unmarried women only will be admitted to the examination. Applicants should at once apply to the United States Civil Service Commission, Washington, D. C., for application Form

cants should at once apply to the Onted States CIVII Service Commission, Washington, D. C., for application Form 1312, or for further information regarding the examination.

The Mortality of the State of New Jersey.—During the mouth ending November 15, 1908, there were 2,602 deaths reported to the State Board of Health, as compared with an average of 3,030 for the previous twelve months. Of the total number of deaths 762 were of children under five years of age, and of these 558 were under one year of age. The principal causes of death were as follows: Typhoid fever, 40 deaths; meales, 6 deaths; claptheria, 41 deaths; malarial fever, 3 deaths; tuberculosis of the lungs, 275 deaths; this cancer, 118 deaths; cerebrospinal meningitis, 25 deaths; diseases of the nervous system, 202 deaths; diseases of the respiratory system (pneumonia and tuberculosis excepted), 133 deaths; pneumonia, 183 deaths; infantile diarrhea, 160 deaths; diseases of digestive system (infantile diarrhea, 160 deaths; diseases of deaths; Bright's diseases, 182 deaths; suicide, 25 deaths; all other the control of the c

The Society of Normal and Pathological Physiology, Philadelpnia, held its third meeting for 1908-1909, on Monday evening, December 14th. The programme consisted of the following papers: Streptothrix Infection of the Tonsil, by Dr. N. Gildersleeve; Some of the Zymogenic Activities of Bacteria, by Dr. D. H. Bergey; The Central Nervous System in the Albino Rat Compared with that in the Wild Mus Norwegicus, by Dr. Shinkishi Hatai; Protozoan Parasites of Man, with microscopic demonstration, by Dr. John M. Swan.

The Brooklyn Pathological Society.—The four hundred and eighty-ninth regular meeting of this society was held on Thursday evening, December 10th. Dr. Adolph Bonner reported a case of ruptured uterus, and exhibited a specimen. Dr. Burton Harris reported a case of hæmatoma, due to infection by the distoma hæmatobium. A case of tuberculosis of the breast was reported by Dr. William Lintz, who presented a specimen. Dr. J. Eddy Blake read a paper on the Bacteriological Diagnosis of Diphtheria, in which he recounted some recent experiences with the laboratory reports of the New York City Department of Health. Dr. Le Grand Kerr read a paper on the Diagnosis of Rheumatism in Children, and Dr. Charles Dwight Napier read a paper on the Diagnosis of the Rheumatic Joint.

Infectious Disease in New York:

If c are indebted to the Bureau of Records of the Department of Health for the following statistics of new cases and deaths reported for the two weeks ending December 12, 10.08.

The Health of Philadelphia.—During the week ending December 5, 1908, the following cases of transmissible diseases were reported to the Bureau of Heath of Philadelphia: Typhoid fever, 43 cases, 7 deaths; scarlet fever, 45 cases, 4 deaths; chickenpox, 105 cases, 0 deaths; diphtheria, 100 cases, 13 deaths; measles, 67 cases, 0 deaths; whooping cough, 13 cases, 0 deaths; tuberculosis of the lungs, 130 cases, 0 deaths; puerperal fever, 4 cases, 6 deaths: ruumps, 11 cases, 0 deaths; cancer, 21 cases, 20 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than that of the lungs, 11 deaths; tetanus, 1 death. The total deaths numbered 524 in an estimated population of 1.532.738 corresponding to an annual death rate of 17.71 in 1.000 population. The total infant mortality was 97; 70 under one year of age, 18 between one and two years of age. There were 37 still births: 21 males, 16 females. The total precipitation was 0.01 inch.

The American Röntgen Ray Society will hold its ninth annual meeting in New York on Monday. Tuesday, and Wednesday, December 28th, 20th, and 30th. The scientific meetings will be held in the New York Academy of Medicine, and an interesting exhibit of x ray apparatus will be held in the Engineers' Society Building. Thirty-ninth Street, between Fifth and Sixth Avenues, which will be open for inspection during the three days of the meeting. All professional men who are interested in Röntgenology are invited to attend the meetings and to inspect the exhibits. At a special meeting to be held on Tuesday evening, December 20th, Dr. John A. Wyeth, president of the New York Academy of Medicine, will preside and deliver an address. Dr. Henry Hulst, of Grand Rapids, Mich, will read a paper entitled Examination of the Lungs by the Röntgen Rays, which will be discussed by Dr. A. Alexander Smith and Dr. Eghert Le Fevre. Dr. Percy Brown, of Boston, will read a paper entitled The Röntgenologist and His Specialty, which will be discussed by Dr. Reginald H. Sayre. Dr. George C. Johnston, of Pittsburgh, will read a paper on the Present Status of Röntgen Therapy. Dr. William Allen Pusey, of Chicago, will open the discussion. Dr. E. W. Caldwell, 480 Park Avenue, New York, is president of the society, and Dr. George C. Johnston, 611 Fulton Building, Pittsburgh to the corretary

The Section in Laryngology and Rhinology of the New York Academy of Medicine will meet on Wednesday evening, December 23rd. The subject which has been chosen for consideration at this meeting is Eruptive Conditions Manifested in the Nose and Throat. Dr. John A. flows Manifested in the Nose and Throat. Dr. John Fordyce will read a paper dealing with the subject from a dermatological standpoint, Dr. Louis Fischer will take up the subject from a pædiatric standpoint, and Dr. Feltx Cohn will treat the subject from the point of view of the laryngologist. A general discussion will follow, which will be opened by Dr. Max G. Schlapp and Dr. George H. Fox.

be opened by Dr. Max G. Schlapp and Dr. George H. Ton-The Health of the Canal Zone.—During the month of October, 1908, there were 292 death the Canal Zone in brospinal meningitis; I from tetanus; 2 from bronchopneumonia; 15 from pneumonia; 15 from diarrhœa and enteritis under two years of age, and 2 from puerperal septichæmia. The morbidity rate for the month among the employes of the Canal Commission was 26.66 in a thousand. The malarial rate was 41.79 in a thousand. The last case of yellow fever in the Canal Zone was discovered in May, 1906. The last case of plague in August, 1905.

Society Meetings for the Coming Week:

Monday, December 21st.—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn., Medical Society.

Tuesday, December 22d.—New York Dermatological Society; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Obstetries and Gynæcology); New York Medical Union.

Wednesday, December 23d.—New York Academy of Medicine (Section in Laryngology); New York Surgical

Society.

Society.

Thursday, December 24th.—New York Academy of Medicine (Section in Obstetrics and Gynæcology); Brooklyn Pathological Society; Hospital Graduates Club, New York; New York Celtic Medical Society.

Friday, December 25th.—New York Society of German Physicians; New York Clinical Society; Academy of Pathological Societoe, New York.

Saturday, December 26th.—New York Medical and Surgical Society; Harvard Medical Society, New York; Lenox Medical and Surgical Society; Harvard Medical Society, New York.

Donations and Bequests to Charitable Institutions. By the will of Dr. William J. Earhart, who died recently in Philadelphia, the following Philadelphia institutions will receive \$5,000 each; The Woman's Homecopathic Hospital; the Children's Homecopathic Hospital, to endow a bed to be

receive \$5.000 each; The Woman's Homeopathic Hospital; the Children's Homeopathic Hospital, to endow a bed to be known as the Jacob R. Earhart, M. D., bed; the Hahnemann Hospital, for a surgical ward; the Woman's Southern Homeopathic Hospital, which will also receive an additional \$5.000 to endow a bed to be known as the Anna May Memorial; and St. Luke's Homeopathic Hospital.

The auditor of the estate of James Hamilton, late of Downingtown, reports that she has paid \$7.292 to each of the following institutions: The Presbyterian Hospital of Philadelphia, the Chester County Hospital, of West Chester, Pa., the Presbyterian Home for Aged Couples and Aged Men, of Bala, Pa., and the Home for Aged and Infirm Colored Persons, of Philadelphia. She also reported that she had paid \$3.604 to the Presbyterian Orphanage of that she had paid \$3,646 to the Presbyterian Orphanage of Philadelphia

By the will of Mrs. Mary E. Ives, who died recently in New Haven, Conn., the General Hospital Society of New Haven receives \$5,000; Grace Hospital receives \$5,000; the New Haven Orphan Asylum receives \$1,000; and the Home

for the Friendless, \$1,000.

By the will of Sarah E. Ward, who died in Boston re-By the will of Sarah E. Ward, who died in Boston recently, the following Boston institutions become residuary legatees: The Cullis Consumptive Home, the Home for Incurables, the Free Home for Aged Women, and the Boston Society for the Relief and Control of Tuberculosis.

The Milwaukee Sanatorium for Tuberculosis has received a gift of \$500 from Mrs. W. T. Cushing

Mr. George Eastman, of Rochester, N. Y., has donated to the Homeopathic Hospital of that city the sum of

Bith of Current Miterature.

 On Certain Evil Tendencies in Medicine and Surgery
 (Concluded), By Maurice H. Richardson.
- 1. The Subcutaneous, Cutaneous, and Conjunctival Use of Tuberculin in Diagnosis.-Lord believes that reactions with any one of the three tests, when properly performed, indicate tuberculosis somewhere in the body. It may not be where our clinical data led us to suspect it, and reactions may occur in the presence of latent, inactive as well as active, foci. This must be constantly in mind in applying the results of the test to individual cases. In patients suspected of tuberculosis a positive test is only one more factor to be considered in establishing the diagnosis, while a negative test is of much greater value and goes far toward disproving the tuberculous character of the disease in question. Of the three tests, von Pirquet's cutaneous method appears to be quite harmless and reliable. It is probably more delicate than the conjunctival and subcutaneous tests, and hence more often responds to latent, inactive, and unimportant foci. So far as can now be judged, there need be no hesitation in its application.
- Transmission and Progress of Tuberculosis in Children through Family Association.-Floyd and Bowditch are of the opinion that, while the educational movement is rapidly making progress in regard to tuberculosis among all classes of people, the full realization of our duty to children has not been appreciated. No adequate provision has vet been made to place these children in good environment that they may regain their health. The work of removing the infected member of the family is being well worked out, but until we can care for all the ignorant and careless consumptives our problem in regard to children will continue to be a large one. Much, however, can be done through isolation, education, and cleanliness. A considerable number of children have been under observation in day camps and in the country. The results have exceeded the expectations. Not only has the general improvement been rapid, but a number of active lesions have become quiescent after a few weeks' treatment. would seem that the child at its receptive age is peculiarly open to ideas in regard to hygienic living, and the recuperative power of the body at this stage in development gives great promise of successful results in treatment. In order, then, better to protect our children, several measures are important. Early notification of all births; better inspection and control of the cities' milk supply; systematic school inspection; housing reform; segregation of advanced cases; required notification of the disease; provision for the care of pulmonary tuberculosis in children; education of all school children on matters of general

hygiene. Nearly all these measures are being enforced in Massachusetts, and, as the forces of sanitation and education advance, the solution of the problem of tuberculosis is nearer.

Syphilis.—Ravogli says of the treatment of syphilis that it is difficult to foresee whether it will be possible to find an antisyphilitic vaccine which, by increasing the opsonic index, will render the organism capable of disposing entirely of the treponema. One thing is sure, that in the mercurial preparations we have a remedy which directly attacks the spirochætæ and improves the general condition of the system, rendering it able to cope with the virulence of these germs. In the meantime we can find the means to attack the treponema directly on the initial lesion where it is developing. We can either destroy it in the locality or at least succeed in modifying syphilis to such a point that it may have a mild course. The local and the general action of atoxyl has been greatly praised by Salmon and Hallopeau. A salve containing 50 per cent. of atoxyl has been used on the initial chancre and at the same time there have been given injections with an atoxyl solution from 10 to 20 per cent. with satisfactory results. The action of the atoxyl on the syphilitic pathological products has been recognized by Hoffmann not only on man but also on the animals. Hoffmann and Uhlenhuth have found in the application of atoxyl a preventive action against syphilis in the animals, and this was later confirmed by Metchnikoff. But it seems that the atoxyl treatment does not protect the patient from the relapses of syphilitic manifestations. In the author's practice the atoxyl injections in cases of severe symptoms did not give him the results which the mercurial preparations have afforded. It can be said then that to-day there has been found another remedy which has true antisyphilitic action. Time and

experience will show whether it is to replace mercury, whether it is to be given in conjunction with mercury, or whether the greatest of all antisyphilitic remedies will still be mercury—Breakey observes that atoxyl must be admitted to an equal footing with mercury as a specific in syphilis, and as an abortive in the disease it is much more reliable. As a remedy it is preferable in all stages and possibly can be depended on to destroy all spirochætæ if used even after the primary manifestation. It is of special service in the graver and more malignant types of the disease. It is not contraindicated in the parasyphilitic manifestations, but even ameliorates many of the symptoms, such as pains and neuralgia in tabes and paresis. Syphilis may be aborted by the prophylactic use of atoxyl adminstered as late as from one to two weeks following inoculation. The failures of previous investigators along these lines have largely been due to insufficient doses of atoxyl. That atoxyl administered by injection. proves to be a true prophylactic is demonstrated by the fact that a typical chancre developed in an animal in which syphilis had been aborted by atoxyl, and which was later again inoculated with syphilis. The same experiment goes to show that prophylaxis does not carry with it an enduring immunity. In the use of the remedy, during any of the stages of syphilis, more rapid improvement than one gets from the use of mercury usually followed. When the disease has become disseminated—that is to say, at any time following the appearance of the primary lesion-constitutional treatment, be it with atoxyl or mercury, must be carried on for a prolonged period, and, while the improvement of particular syphiltic maniiestations is more rapid with atoxyl than with mercury, recurrences appear on the cessation of the treatment. The explanation of the action of mercury or atoxyl on the spirochætæ must still be found. It is probably through the effects of the drugs in attenuating the germs or in stimulating phagocytosis. Beyond a certain dose, the amount given has no further effect on the destruction of the microorganisms. The small doses are ineffective and useless, while large ones produce toxic effects, varying from slight headache, nausea, vomiting, colic, and possible ocular effects and subsequent paresis. ordinary dose should be 50 centigrammes. This should be given hypodermically at intervals of one or two days and repeated from four to eight or ten times, after which an interval of rest should be observed, or treatment may be continued by one of the other specifics of mercury or iodine. Very good results have been observed in the alternation of these remedies, or even in using them together at the same time. At present, atoxyl, as a remedy, promises much. In unusual dermatoses of uncertain character, the recovery of the Spirochæta pallida establishes a positive diagnosis and indicates the necessary treatment. The failure to find spirochætæ, however, proves nothing and we are thenno better off than we were years ago. In such cases, the Wassermann test may be used as a necessary diagnostic resort. Outside of the larger medical centres, such diagnostic measures are quite impracticable, and in the hands of the general practitioner impossible. The fact remains that in many cases a diagnosis must and will depend entirely on the clinical picture presented. To the attending physician still remains the necessity of recognizing syphilis from the symptoms manifested by the patient.

12. Air Infection of Minor Importance.—Chapin states that the theory of the aerial transmission of disease was developed as the most reasonable way of explaining the phenomena of infection, but contact inefection with carriers and mixed cases affords a better explanation of the phenomena. The best medical thought has been steadily restricting the supposed sphere of aerial transmission, and only a few authorities now assert that disease is carried by the atmosphere outside of dwellings, and this assertion is made only with regard to smallpox. Bacteriology teaches that former ideas in regard to the manner in which diseases may be air borne are entirely erroneous; that most diseases are not likely to be dust borne, and they are spray borne only for two or three feet, a phenomenon which after all resembles contact infection more than it does aerial infection as ordinarily understood. Tuberculosis is more likely to be air borne than is any other common disease. Animal experimentation indicates that tuberculosis may be air borne, and that plague and some other diseases are not, but pathology has not determined, as is sometimes alleged, that even pulmonary consumption is an air borne disease. There is no good clinical evidence that the common diseases are air borne, but there is considerable clinical evidence that scarlet fever, diphtheria, smallpox, measles, whooping cough, typhoid fever, and plague are not easily transmissible through the air.

14. A New Method for the Quantitative Estimation of Albumin in Urine.—Goodman and Stern have made use of the solution of Tsuchiya-phosphotungstic acid in ninety-six per cent. alcohol and hydrochloric acid—as a basis for a titration method. They dissolved I gramme of crystallized albumin in 100 c.c. of distilled water (solution A). Of this they took I c.c. and diluted with 9 c.c. of distilled water (solution B), so that in the 10 c.c. there was 0.01 gramme of albumin, in 1 c.c. 0.001 gramme, and in o.I c.c. 0.0001 gramme. They put in a test tube 5 c.c. of the following solution: Phosphotungstic acid, 1.5 grammes; hydrochloric acid (cone), 5 c.c.; alcohol, ninety-five per cent., q. s. ad., 100 c.c. They found that if the solution of albumin (solution B) was added with a pipette graduated in 0.1 c.c. it took o.1 c.c. to cause a cloudy precipitate with the phosphotungstic acid; in other words, o.1 c.c. of the albumin solution contained 0.0001 gramme albumin. To prove the delicacy of this test they took I c.c. of solution B and diluted it with 9 c.c. of distilled water, so that in the 10 c.c. there was 0.001 gramme albumin, in 1 c.c. 0.0001, and in 0.1 c.c. 0.00001 gramme, and they found that it required exactly I c.c .or 0.0001 gramme albumin to cause a precipitate. Having established the fact that the acid solution precipitated exactly 0.0001 gramme albumin, they applied their method to urine. First the Heller test was made, and if much albumin was present the urine was diluted I in 10; if not, undiluted urine was used. Five c.c. of the phosphotungstic acid solution was put in a test tube, and then with a 2 c.c. pipette graduated in tenths of a cubic centimetre, the filtered urine was added to this, shaken after the addition of each tenth, and urine added until a whitish cloud appeared. The number of tenths of a cubic centimetre was read and expressed in terms of 100 c.c.

For example, if it takes I c.c. of diluted urine (I in IO) there is 0.0001 gramme albumin in 0.1 c.c. of undiluted urine, or in 100 c.c. there is 0.1 gramme albumin, or I gramme in 1,000 c.c. On the other hand. if 0.7 c.c. diluted urine (I in IO) is used, then 0.07 c. c. diluted urine equals 0.0001 gramme albumin, 7 c.c. undiluted urine equals 0.01 gramme albumin, and 700 c.c. equals I gramme albumin. The following equation gives the percentages: 700:1.0= 100: X or 0.142 per cent, or 1.42 gramme per thousand. The authors state that their method for determining the amount of albumin by titration is to be recommended on account of its simplicity, accuracy, and the rapidity with which one obtains results. It is applicable to urines containing but faint traces of albumin, such as those in cases of febrile albuminuria, which are not suitable for the Esbach method. The method is also accurate for large quantities of albumin. So far they have been unable to find any sources of error in their method such as must be taken into consideration with the Esbach albumin-

- The Tuberculosis Problem in the Philippines and the Elimination of Intestinal Parasites as the First Step in Its Solution,

 By Victor G. Heiser.
- Neuroses of the Nose,

By CHARLES PREVOST GRAYSON.

The Ileocolic Circle.—Robinson observes that the ileocolic circle is formed by the bifurcation of the injejunal artery into the ileocolic artery and ileal artery and completed by their distal inosculation. In other words, the jejunal artery divides into the ileocolic and ileal arteries which reunite some five inches distalward forming a constant mesenteric vascular circle—a constant fixed primordial circular vascular landmark. The ileocolic circle is located in the ileocolic angle and is a constant struc-It may be accompanied by mesenteric apertures, from insufficient vascular nourishment, which may serve for hernial strangulation. The ileocolic circle is frequently divided into compartments by arteries of varied dimensions, which are destined to nourish the mesentery within the circle or are bifurcated loops, branches of the main circle. The clinical significance of the ileocolic circle is that its right circumference—96 per cent. (i. e., the ileocolic artery)—is the main source, or the origin of the arteria appendicularis. The ileocolic circle, existing in the form of an oval, measures practically 2x6 inches. The dimension of the ileocolic circle depends upon the location of the bifurcation of the jejunal artery and the length of the ileal artery. The jejunal artery may bifurcate proximal, on a level or distal to the origin of the distal mesenteric artery, i. e., in the region of the third lumbar vertebra. The ileocolic circle may possess, imposed on its periphery, a series of minor vascular arches. It is a primordial vascular landmark destined to nour-

ish the ileum and cæcum (with appendix as an ancient stomach). The ileocolic circle is associated and in relation with the right psoas, distal ileum, cæcum, right ovary, right oviduct, ureter, common

iliac, and the treacherous, dangerous appendix to which it primarily, chiefly, and directly emits the vascular supply. It is directly associated with the ileocolic arches. By placing it mesenteron on a leftward tension one may view plainly the "ileocolic circle" though not injected. By the aid of the ileocolic circle the anatomist can unfold with greater practicality the vascular relations of the ileum and cæcum, but especially those of the appendix. The ileocolic circle is an important practical physiological vascular landmark. The base of circulation is anastomosis, which is here indicated in its typical form—that of a circle; collateral anastomosis is complete, perfect. Our chief means to control the blood current for therapeutic purposes is through the "inosculating circle," e. g., the uteroovarian circle. Physiologically the ileocolic circle is supplied with such numerous radiating branches of marked dimensions that if it were ligated ample collateral circulation would preserve tissue nutrition and furnish sufficient blood volume for function of the tractus intestinalis (sensation, absorption, secretion, peristalsis). The ileocolic circle presents practical pathological conditions. Apertures of the peritonæum within the ileocolic circle may produce (atrophic) peritoneal apertures from lack of blood supply, sufficient to allow intestinal coils to become strangulated. Arterial sclerosis of the ileocolic circle may occur to sufficient degree to interfere with nutrition of tissue and enterocolonic function (sensation, absorption, peristalsis, secretion), particularly that of the appendix. Should an embolus appear in any segment of the ileocolic circle the collateral circulation is sufficiently abundant to preserve tissue and function and reestablish collateral circulation. The ileocolic circle is one of the most important vascular landmarks, especially in relation to the dangerous and treacherous appendix-dangerous because perityphilitis kills, and treacherous because its capricious course cannot be prognosticated.

4. The Tuberculosis Problem in the Philippines.-Heiser says that in tropical countries, where tuberculosis and hookworm diseases are coexistent, the elimination of the hookworm will produce better results in diminishing the mortality from tuberculosis than any measure that has as yet been tried upon a large scale; at the same time the general mortality can be markedly reduced. The annual mortality among 3,000 prisoners in Manila was reduced from 75 to 20 by the elimination of intestinal parasites; 50 per cent. of this number formerly died of tuberculosis. This was accomplished after the measures heretofore recommended by good authorities had been faithfully but unsuccessfully offered. Increasing the resistance of an individual to tuberculosis by the elimination of intestinal parasites has proved very effective in reducing the incidence of the disease. As a result of a campaign of education and by providing more hygienic houses, the number of cases among the general population of Manila was apparently reduced from 15.6 to 13 per cent. of the total mortality.

I. Diabetes Mellitus .- Pavv, in his second lecture on diabetes mellitus, discusses the question of the fate of the sugar taken in with the food, where it is metabolized, etc. Everything points to a disappearance of the sugar at the seat of absorption into the intestine. Nowhere else do we find such activity of protein formation. Quiescence prevails at a period of fasting, but after food ingestion, extremely active bioplasmic growth starts into operation, the newly formed bioplasm flowing in the shape of lymphocytes, through the chyliferous vessels into the circulatory system and giving rise to the digestive lymphocytosis which is observed to follow the ingestion of food. The main disposal of the absorbed sugar is effected by the assimilative action occurring within the mucous membrane of the intestinal canal, and what escapes being disposed of here, passes through the portal vein to the liver, which exerts a supplementary action in checking its flow into the general circulation by producing transformation into glycogen. Food that has been broken down and placed in a fit state by digestion for absorption is at once dealt with at the seat of absorption and rebuilt into an elaborated form. Dextrose and peptone are alike recognizable at the seat of obsorption, but both thereafter disappear. At the same time, and at the same spot, there is an active bioplasmic growth taking place, and bioplasm is known to feed upon dextrose and upon peptone. The lymphocytes, which constitute the growing material, can be followed from the villi into the absorbent vessels, and thence through the thoracic duct into the vascular system. Concurrently during the digestion period there is a large accession of lymphocytes-a digestion lymphocytosis. The next event in the life history of the lymphocyte is lymphocytolysis. There can be no doubt that production and disappearance constitute a routine procedure, and the disappearance is attended with a melting down and transformation into the protein constituents of chyle and blood plasma, thus bringing this tissue pabulum into direct relation with the food. Looked at in this way, the tissues draw their nutrient supply from material elaborated from the digestion products at the seat of absorption, instead of the digestion products being conveyed as such through the circulatory system to the tissues, an event that, on account of their small molecular nature should, but does not, make itself evident by their running off with the urine. The breaking down of protein material into utilizable and nonutilizable portions may very consistently take place within the lymphocyte through the instrumentality of intracellular enzyme

action. This view is in harmony with the fact that the period at which the increased elimination of urea shows itself after the taking of food, about corresponds with that of maximum activity of lymphocyte autolysis. Impermeability of the kidney to sugar is a pure fiction based upon the false conception of healthy urine being free from sugar. The urine stands in very sensitive relationship to the blood with respect to sugar. It is an indicator of the state of the blood as regards sugar, no matter whether the amount existing is large or small, and if sugar is reaching the circulation, as is contended for under the glycogenic theory, it can not escape being rendered evident by the urine, just as, indeed, happens in connection with diabetes.

2. Typhoid "Carriers." - Davies and Hall have studied a series of cases of typhoid "carriers" with special reference to their "effectivity"-i. e., the times and seasons of the year when they transmit the infection. A most interesting point brought out is the almost uniform absence of "effectiveness" of the carriers during the early months of the year. It is now known that typhoid bacilli may live for considerable periods in the gallbladder and hepatic bile passages, and that the carrier harbors the typhoid bacillus continuously. What is the meaning of the "ineffective" period? It may be due to periodicity in the virulence of the bacillus, the organism living a hibernant existence in the intrahepatic and extrahepatic biliary passages during these months, and becoming actively parasitic on reawakening for the remaining months of the year. The period of effectiveness, again, may be dependent upon the type of food taken, the general tissue metabolism, or the condition of the heat regulation apparatus. This seasonal effectivity may offer an explanation of the waves of endemic typhoid fever, the May revival starting the supply of fresh infections which subsequently develop by extension into the autumnal outburst. The writers hold that where typhoid fever is endemic there should be systematic examination of the fæces of convalescents or suspected carriers, made day by day and extending over long periods. The marked excretion of the typhoid bacilli during the later weeks of the acute attack does not appear to have its parallel in the carrier. The agglutinating properties of the blood may afford evidence of the "effectiveness" of the carrier. In conclusion are given an excellent set of instructions for typhoid convalescents to be given the patient when discharged from a hospital.

3. The Common Cold .- Allen asserts to have placed the bacteriology of the common or catarrhal cold upon a sounder footing, indicated means whereby a distinctive diagnosis of the causal organism or organisms may be made in any given case from a consideration of the clinical features, and to have demonstrated the utility of vaccine therapy not only in shortening acute attacks, but also in curing chronic cases and in securing immunity, more or less complete, from further attacks, acute or chronic, in those susceptible to this troublesome and common complaint. He defines a cold as a local inflammation of any portion of the respiratory tract, from the mouth and external nasal meatus to the bifurcation of the bronchi, together with the sinuses attached thereto. Inflammations due to the ordinary pyogenic cocci are excluded. The acute cold exhibits the following stages: I. Local anæmia of the mucous membrane. This is followed by local hyperæmia. 2. After infection there is a period of incubation, during which the hyperæmia increases, and there is dryness and tickling of the throat and nose, and general malaise. 3. The third stage, or "catarrhal plateau" is characterized by greatly increased mucous secretion, with sore throat, cough, and general malaise. 4. In the subacute stage, the mucous discharges become thick and vellow in color, containing leucocytes and lymphoid cells. 5. The last stage is one of true chronicity, and is marked by continuous excessive secretion of thick mucous. The most common causative organisms are the bacillus of Friedländer, the bacillus septicus, the influenza bacillus, and the micrococcus catarrhalis. Their relative frequency varies widely in different epidemics. Each organism produces a more or less distinct type of cold. True chronic nasal catarrh is usually due to the bacillus of Friedländer, while the micrococcus catarrhalis is largely responsible for chronic tracheitis. Subacute colds appear to be due to either the bacillus of Friedländer, to the micrococcus catarrhalis, or micrococcus paratetragenus. The persistent hacking tracheal or "winter" cough is probably due to one of the two latter organisms. The mode of onset and condition of the throat are helpful in the distinctive diagnosis. If the fauces and pharynx are first affected, either the micrococcus catarrhalis or the bacillus septicus is certainly present; if the larynx and trachea become speedily involved the former of these or micrococcus paratetragenus is indicated; to hear a patient cough is sufficient for a diagnosis if m. catarrhalis or m. par-The constitutional symptoms of the atragenus. bacillus septicus are but slight, those of the micrococcus paratetragenus are moderate, while the general malaise in the cases of the three others may be extreme. The temperature is high only in the case of influenza. The prognosis in cases of infection with Friedländer's bacillus should be very guarded, as there is risk of ear and accessory sinus involve-The same is true of the micrococcus catarrhalis and the influenza bacillus where extension downwards is also to be feared. A good prognosis can be given in the case of the bacillus septi-

LA PRESSE MEDICALE. October 28, 1908.

The Method of Having the Patient Lie on his Right Side in the Diagnosis and Treatment of Atonic Gastrectasia, By PAUL CARNOT.

Lying on the Right Side in the Diagnosis and Treatment of Atonic Gastrectasia.—Carnot recommends to test a patient in whom atonic gastrectasia is suspected in the following way: In the morning the stemach contents are evacuated with the stomach tube and then half a litre of water is introduced. The patient then maintains an upright position, or is seated, for an hour, when the stomach tube is reintroduced to ascertain whether any water remains accumulated in a pouch below the level of the opening of the pylorus. The second test is in the same manner except that, after the introduction of the water, the patient is caused to lie on his right side for an hour, so that the opening of the pylorus

is on a lower level than the rest of the stomach. If the pylorus is permeable there will remain at the end of an hour at most only an insignificant quantity of water. By the maintenance of this position after meals he asserts that it is possible to give such a patient sufficient alimentation without exposing him to the ill effects of gastric surcharge or increasing the ptosis. He says that every one of his patients treated in this manner was relieved and underwent a rapid amelioration.

Studies Concerning the Relations between Human Tu-berculosis and Tubercle Bacilli and the Tuberculosis and Tubercle Bacilli of Cattle (Continued), By Johannes Fibiger and C. O. Jensen. Elementary and Colloidal Sulphur (Sulfidal), (Concluded),

1. Complement Binding.—Halberstädter, Müller, and Reiche assert to have demonstrated that hæmolysis may be checked by serum from patients with scarlet fever in conjunction with alcoholic extract from a syphilitic liver. This checking of hæmolysis is not usually as marked as when syphilitic serum is used, but yet under certain circumstances it may be indistinguishable even quantitatively from the reaction induced by syphilitic sera.

3. Blood Pressure in Chronic Nephritis .- Engel says that the high systolic blood pressure is truly a symptom of atrophic kidney, while, on the contrary, uncomplicated inflammations of the kidney, either wholly or mainly parenchymatous in character, so long as they are compensated, exhibit absolutely no increase of blood pressure, and that therefore the theory that ascribes nephritic hypertension in chronic parenchymatous form of renal disease rests upon confounding it with cardiac hyperten-

7. Elementary and Colloidal Sulphur.-Nevinney says that the absorption of precipitated sulphur varies, and that an increase of the neutral sulphur is to be observed, while, on the contrary, the absorption of sulfidal always remains the same, and all of the sulphur appears to become oxidized in the organism. He recommends sulfidal as preferable in all cases in which sulphur is indicated.

By PFANNENSTIEL. (Concluded), 11. Johann Hermann Baas, By BIEDERT

12. Medical Poems of the Early Part of the Eighteenth By STÖCKER.

2. Resistance of Bacilli of the Type Paratyphus B.—Mayer has shown by his investigations that under certain circumstances paratyphus bacilli can maintain their vitality for years in dried human fæcal matter protected from the light, and points out the importance of this fact in the explanation of certain epidemics.

3. Fulguration Treatment of Malignant Tumors.—Schultze reports twelve cases of malignant tumors in which he employed the fulguration treatment without material benefit. He condemns

the method as unsatisfactory.

4. Calmette's Ophthalmoreaction.—Schrumpf reports a case in which permanent injury to the eye resulted from the application of Calmette's test, and concludes that when every precautionary measure has been observed Calmette's ophthalmoreaction may cause permanent injury to the eye, and that therefore it should be used with great circumspection, and the patients should be informed beforehand of the danger.

7. Atropine in Incarcerated Hernia. - Rabl reports four cases of hernia irreducible by taxis in which spontaneous reduction took place after subcutaneous injection of atropine. An interesting point in connection with these cases is the disparity of ages of the patients. One was three years old. one twelve, one thirty-five, and the fourth eighty-

Icterus Gravis of the Newly Born .-- Pfannenstiel concludes his very elaborate paper with these considerations concerning the nature of this disease. It has been very often met with repeatedly in children of the same parents, between whom may have been born other children who were healthy or only slightly affected by icterus. There appears to be no difference between the mild form and the so called physiological icterus of the newly There are transition forms between the mildest and the most rapidly fatal forms of icterus neonatorum. The ætiology is unknown. Syphilis has been demonstrated in no case. Other infections are improbable. The apparent causes found in solitary cases are mentioned. For treatment he recommends the promotion of diuresis, subcutaneous infusions of salt solution, warm baths with cold sprinkling, enemata of camomile tea, and anything else indicated by the symptoms.

1. The Cutaneous and Ophthalmic Tuberculin Test in Infants under Twelve Months of Age .-Shaw believes that a working knowledge of clinical and laboratory aids to diagnosis is necessary to practise medicine conscientiously. An early diagnosis of tuberculosis is especially necessary in young children. The earlier it is made, with proper treatment, the greater the chance of recovery. Von Pirquet found a characteristic reaction after cutaneous vaccination with tuberculin and established the cutaneous tuberculin test. Wolff-Eisner obtained a reaction on the conjunctival mucous membrane after instilling a drop of weak tuberculin solution. Both he and Calmette found it constant in tuberculous subjects. In a large number of reported cases of the cutaneous in young infants no reaction has been reported. The author could find no detailed account of the ophthalmic test in young infants. He personally used the ophthalmic test on eighty-one infants under twelve months without reaction. The cutaneous test in the same infants gave reaction in one case. The cutaneous test is simple and without danger, and is preferable to the ophthalmic test.

3. Present Knowledge of Whooping Cough .-Donnally states that recent statistics show that the mortality of whooping cough in children under five years of age is greater than that of any other disease except diarrhœa, enteritis, pneumonia, convulsions, meningitis, and diphtheria. Its mortality is chiefly due to its complications. The disease is more protracted and its complications more frequent during raw and inclement weather. The sputum of the disease in its paroxysmal stage contains a minute hæmophilous bacillus almost indistinguishable from the bacillus of influenza. This is obtainable in pure culture only on hæmoglobin media. The disease is contagious during its entire course, one attack usually gives immunity for life, and the incubation period is indefinite. The examination of the chest in an uncomplicated case shows nothing abnormal. Examination of the blood shows increased leucocyte count with lymphocytosis. Tuberculous infection is

one of the frequent accompaniments.

4. The Leucocyte Count of Normal "Institutional" Children and those Suffering with Pertussis .- Mosenthal offers the following conclusions: 1. The average normal leucocyte count of "institutional" children is higher than is usually given. The normal count in such cases varies between 29,600 and 7,000. 2. The percentages of the different varieties of leucocytes show diminished polymorphonuclear cells, and increase of mononuclear. The percentage of the former increases with age as in other normal children. The percentage of eosinophiles is within normal limits. 3. In the catarrhal stage of pertussis the leucocytes are doubled, the mononuclear cells increased by 5.5 per cent. In the convulsive stage the changes in the blood count are similar. 4. In cases in which there is only an afrebile cough there may be overleucocytosis. The polymorphonuclear elements are increased at the

expense of the mononuclear. 5. Overleucocytosis with increased percentage of mononuclear cells at the expense of the polymorphonuclear aids the diagnosis of pertussis in the catarrhal stage.

By R. PARNELL and R. GOMPERTZ.

Home Treatment and Nursing of Pulmonary Tuberculosis in Dublin.—Thompson be-lieves it is now admitted that early cases should be treated in sanatoria, if possible, both for the immediate effect upon the patients and the educational effects upon others, and that advanced cases should be cared for in homes of rest, these cases being the ones which do most to spread the disease. The great frequency of tuberculosis in Ireland stimulated the formation of a Hospitals' Tuberculosis Committee. After six months this committee reported 157 patients treated and nursed at their homes. Of this number forty-seven were greatly improved, eleven being able to resume their work. Forty-one were placed in suitable institutions, eight families were removed to more healthy surroundings. Rooms were disinfected and sputum flasks distributed, food and clothing supplied, children sent to the country for convalescence, etc. The nurses instruct patients and their friends as to ventilation, as to the proper utilization of the available supply of food, proper methods of cooking, and as to the way to keep themselves thoroughly clean. The committee proposes to erect platforms and shelters to enable patients to be out of doors as much as possible, and is encouraged to feel that the method has obtained a firm foothold in

2. Infective or Ulcerative Endocarditis .-- Tirard thinks the diagnosis of this serious disease is often very difficult. As seen in practice it does not always correspond with the description in books. In a series of narrated cases the most prominent symptem was oscillation of the temperature, with rigor or evidence of infarction. Other symptoms were petechiæ of the extremities, vomiting, ashy discoloration of the skin, and heart murmurs. A murmur is not always present; when present it may be loud and persistent if added to preexisting chronic valvular lesion, or it may be soft and finally become inaudible. Attention is called to the fact that the deposits upon the heart valves are invariably on the side over which the blood passes in its onward flow, and that the vegetations are soft and spongy. As they do not prevent closure of the valves an absence of cardiac

murmur is not necessarily strange. The vomiting and retching, which may follow a succession of rigors, without any discoverable gastric, hepatic, or cerebral change, may be considered as analogous to the vomiting of uræmia or of cholæmia. The septic cerebral, and typhoid types of symptoms are probably due to the presence of a toxine in the circulation

Adherent Pericardium.—Fenton finds (1) 3. that there are two types of adherent pericardium at different periods of life. The first or grave form occurs under the age of thirty; the second, which has little clinical significance, after that age. (2) That a history of rheumatism is usually associated with the former, and is absent in the latter. (3) That the former is usually accompanied with valvular disease, but not the latter. In some of the former class of cases valvular disease is absent, the morbid phenomena being produced solely by the condition of the pericardium. In some of the latter there may be coincident valve disease. The cardiac enlargement may be due to the following: 1. Obstruction to systole leading to hypertrophy, subsequent dilatation, and failure. 2. That the effects owe nothing to the pericardial adhesion, but are explained by the valvular incompetence. 3. By degeneration of the cardiac muscle, occurring with the initial attack of pericarditis and permitting dilatation. The chief diagnostic points consist in a recognition of the possibility of the lesion in any case in which, in early life, the cardiac symptoms are grave, but the signs slight, or in which excessive enlargement of the heart exists in the absence of aortic disease.

4. Bier's Method of Passive Congestion .-Wakefield states that as a means of treatment for rheumatoid arthritis this is far from a panacea, but is as valuable as any means we possess. If the disease is due to microorganisms congestion should act remedially by causing autoinoculation. It may usually be depended upon to relieve the pain of the disease. The bandage should be applied when the pain comes on and removed when it has disappeared. In active tuberculosis Bier's direction is that the bandage should not be used more than one or two hours daily. As improvement occurs the bandage should be used with diminished frequency. In joint tuberculosis immobilization should be avoided, as it may cause ankylosis. Contraindications to conservative treatment by congestion are (1) commencing amyloid disease and advanced phthisis; (2) large abscesses filling the entire joint cavity and demanding operation; (3) faulty position of the joint so that cure would give a less useful result than resec-

5. Gastric Ulcer .- Mackenzie states that the position of this lesion would indicate its probable relationship to the gastric juice. Ulceration or its sequels is probably, however, a cause rather than a consequence of the excessive secretion of gastric juice, or of juice of excessive acidity. Einhorn is quoted to the effect that chlorosis, anæmia, and amenorrhoa, frequent concomitants of gastric ulcer, are also associated with hyperacid gastric juice. The sharp angle in the lesser curvature of the stomach determines the frequent location of ulcers in this vicinity. Bad teeth and constipation have also been noted as frequent attendants of this disease, also it occurs more frequently among the poor than among

those who can always have a liberal diet. One of the principal essentials in treatment is rest in bed. fluid or soft diet is important, and rectal feeding may be necessary for a time. Hæmorrhages are not necessarily of serious importance unless they are of frequent occurrence, when operative interference will be required. It must not be forgotten that the latter is a very serious step.

- Vaccine Therapy in Tuberculous Disease with Mixed Infection, By D. P. D. WILKIE.
- Congenital Diaphragmatic Hernia in an Old Man, By ALEXANDER DON.

Vaccine Therapy in Tuberculous Disease. -Wilkie reports his observations on the opsonic ex-

amination and vaccine treatment of patients with mixed infections in tuberculous lesions, who all had undergone, at some time, a surgical operation to eradicate the tuberculous disease. He found that the healing of the wound after a radical operation for the removal of tuberculous disease with mixed infection depended (a) partly on the nature of the secondary organism, e. g. with Staphylococcus albus much more favorable than with Staphylococcus aureus or streptococcus, and (b) partly on the opsonic index of the patient for the invading organism. One can with advantage raise the patient's opsonic index for the invading organism previous to operation by cultivating the organism from the wound, making a "personal" vaccine and injecting this into the patient. Operation must be delayed till the negative phase following the vaccine injection is over, and if possible one should operate during the positive phase. With staphylococcus the negative phase is generally over in thirty-six hours. In cases where after operation sinuses have persisted, improvement in both general and local conditions follows treatment with a suitable vaccine. The local action can be greatly enhanced by combining, where possible, the vaccine treatment with the application of passive congestion by an elastic bandage (Bier), or by the use of suction cups (Klapp). Our author concludes that in the great majority of cases of localized infective lesions vaccine treatment may be carried out with little or no risk, and often with great advantage to the patient, without making regular opsonic examinations; such examinations, unless made very frequently, are apt to be misleading, and no one should be deterred from employing vaccine therapy because of the difficulty or impossibility of having such examinations made.

2. Rational Spinal Support.—Frauenthal remarks that unless a brace rests upon the pelvis, by collar across the crest of the ilium, it is ineffectual and harmful. When disease occurs above the seventh dorsal vertebra, either the patient should be treated in the recumbent position for months or vears, or a brace or jacket applied, with jury mast attached, that will take off the superimposed weight above the point of disease. Children under three years of age with tuberculosis of vertebræ should be treated in the recumbent position in bed or on a portable cuirass. Recognized fundamental principles of applied mechanics have not been made use of in the application of the braces now generally in use in tuberculous disease of the spine. results made manifest in hideous deformities are due to failure to apply such scientific principles of mechanics in the fitting of braces, as would be applied in other mechanical endeavor. In the mechanical treatment of tuberculous joints we must decide which is best, viz., (1) fixation, (2) fixation with traction (thus trying to separate the inflamed surfaces and prevent the absorption produced by muscular and ligamentous contraction), (3) traction with motion.

I. Treatment of Tetanus with Subarachnoid Injections of Magnesium Sulphate.-Miller reports fourteen cases which were treated with magnesium sulphate. Of the eleven patients who received injections five recovered. Of the three who were treated by infusion all recovered. The cases in the first group were mostly of a severe type; those in the second group were mild cases. thinks it can be affirmed that by the use of magnesium sulphate we can obtain complete muscular relaxation in almost all cases of tetanus. From the reported results there is distinct benefit to the patients with this disease, the rapid exhaustion due to convulsions being prevented, and ability to take food restored. While there is as yet comparatively little clinical evidence upon which to base general statements, it does, however, seem possible to avoid the dangerous effects of an overdose of magnesium salts, while it is likely that when the technique has been thoroughly worked out the treatment will offer the possibility of saving a great many patients with tetanus who at present are given up as hopeless at first sight.

Traction in the Treatment of Hip Disease. -Bradford and Soutter affirm that the surgeon has several methods for the treatment of hip disease under his control. He can protect the joint with crutches, and can aid the patient in obtaining means for increased activity and fresh air. He can prevent deformity and limit bone destruction by exaggerated bone pressure, thus checking the process and promoting bone healing. The test of success will be the degree of resulting deformity, the object being a cure without distortion or disability. Traction can be employed without using expensive or elaborate apparatus. It does not demand unusual skill from the surgeon or nurse, nor more attention in its management than is easily possible. It meets a pathological indication in the stage of muscular spasm, it should be applied to check undue bone crowding, it furnishes a satisfactory measure of fixation of the joint when efficiently applied, and it enables one to obtain better results in hip disease than by measures which dispense with it.

3. The Heart in Pulmonary Tuberculosis .-Brown emphasizes the importance of study of the heart in this condition with reference to diagnosis, prognosis, and treatment. The heart itself may be diseased or not diseased in a given case of pulmonary tuberculosis. In considering the latter situation the author regards (1) the position of the heart; (2) its size; (3) dilatation with the area of cardiac dulness; (4) auscultatory phenomena; (5) the pulse, including blood pressure; and (6) palpitation. The position of the heart in patients with pulmonary tuberculosis depends directly upon the pathological changes that have taken place in the lungs; in other words, it may be displaced upward, downward, to right or left. In size the heart, with tuberculous lungs, may be large, small, or normal. Dilatation of the heart occurs far less frequently than would be supposed, and then only late in the disease. Careful auscultation of the heart reveals in a certain portion of patients with pulmonary tuberculosis accentuated second pulmonic sound, functional murmurs, etc. The frequency and tension of the pulse are changed early and often permanently. Palpitation is an accompaniment at puberty and the menopause; it may precede hamoptysis, and accompany dyspepsia.

4. The Heart during the Early Period of Convalescence from Acute Infectious Disease.--Robinson thinks the importance of this subject has long been recognized and has been elaborated in textbooks, but too often in an insufficient manner. No organ requires such care during convalescence as the heart, the prevention of dilatation defining in many cases the hope of future vigor and well being. This is especially true in convalescence from typhoid fever, diphtheria, influenza, pneumonia, scarlet fever, and acute articular rheumatism, for in these diseases there is cloudy change and fatty degeneration of heart muscle and nerve fibre. The heart is soft and may contain thrombi, and there may be endocarditis. This means that one should not get up and out of bed from an infectious disease until sufficient time has elapsed after the disappearance of the disease for the heart to recuperate. Still less should one resume any ordinary duties until the heart has regained its normal tonus. Failure to observe these precautions is responsible in many instances for the sudden dilatation of the heart, with fainting and collapse,

and perhaps with death.

5. Nonfatal Coma in the Course of Diabetes.— Camac reports such a case, which was under observation nine months. The coma was recovered from, but the patient died four months later with hemiplegia. The conclusions are that the case was one of syphilitic arteriosclerosis, with involvement of the pancreas, kidney, and brain. The sclerotic changes in the pancreas led to the diabetes, those in the kidney to the chronic nephritis, and those in the brain to the softening with hemiplegia, to the feeble mentality, and possibly to the coma. The author states that the only coma clinically defined in diabetes is the dyspnotic type, and the only coma chemically defined is that due to acidosis and acid intoxication. The nephritis and brain condition are most important in the consideration of the coma, but in the absence of any clear knowledge of the origin of coma in uræmia or brain softening the mere statement of their presence is not sufficient to exclude other factors resulting from disturbed metabolism, which subsequent investigation may disclose.

6. The Pathological Changes in the Thyreoid Gland as Related to the Varying Symptoms in Graves's Disease.-Wilson feels warranted in the following statements from the clinical point of view: 1. Very early acute cases show pathologically hyperæmia and cellular hyperplasia in more or less of the gland, if the more enlarged lobe has been removed. 2. Later acute cases show greater parenchyma increase and increased absorbable secretion. The increase in parenchyma is in proportion to the severity of the symptoms. 3. Cases in which there is remission of toxic symptoms show evidence of decreased function, or of probably decreased absorption. 4. Those who have recovered from toxic symptoms, but still suffer from heart or nerve lesions, or from myxœdema show exfoliated epithelium and thick nonabsorbable colloid. 5. The mild cases, of long duration, show increase of parenchyma by the multiplication of alveoli, but no increase of functional power of the individual parenchyma cells. 6. Simple goîtres should be regarded as multiple retention cysts, filled with nonabsorbable secretion, cell detritus, etc.

Proceedings of Societies.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Meeting of May 18, 1908.

The President, Dr. ROBERT T. MORRIS, in the Chair.

Carcinoma of the Cheek Treated by Means of the X Ray, Thyreoid Extract, and Thiosinamine.

—Dr. C. Am Ende presented, at the request of the president, a case of cancer which developed from an accidental injury received two years ago. Although the sore was immediately cauterized and then variously treated, it failed to heal. About a year ago a small whitish spot made its appearance. This continued to grow larger and larger, and, Dr. Robert T. Morris having been consulted, he referred

the case to Dr. Am Ende. When it was first seen by him, on December 29, 1907, he found an erosion on the inner side of the cheek somewhat larger than a silver dollar and covered by an adherent whitish mass of necrotic tissue. A similar necrotic streak lined the neighboring gum, which below it was inflamed and swollen, and the submaxillary gland was enlarged, indurated, and firmly attached to the bone. Scrapings from the erosion were found to be sarcomatous, and several experts had considered the case hopeless. The treatment consisted, besides some local applications, of x raying twice a week and the internal administration of three teaspoonfuls daily of the speaker's thyreoid fluid extract, together with two grains of thiosinamine twice daily. In addition, one grain of thiosinamine was given hypodermically, at first three times a week, and later twice a week. The mutually supporting activity of the x ray and the thyreoid fluid extract upon deep seated neoplasms, he said, had been demonstrated before, and the thiosinamine appeared to extend the effect to more indurated growths. Under this treatment the gum became normal in about four weeks, which indicated that the invasion was superficial as yet, and at present the erosion was nearly healed over, although the new mucous membrane did not yet feel normal. The metastatic induration was considerably smaller also, so that its disappearance' would seem only a question of time. Whether or not the prolonged use of thiosinamine and kindred drugs might affect normal connective tissue was a question which Dr. Am Ende thought should be taken into consideration.

The patient himself expressed the complete relief from the agonizing suffering previously experienced which had resulted from the treatment described.

The Ultra Violet Ray, High Frequency Currents, and Tabes.-Dr. HENRY G. PIFFARD said that in the discussion on tabes at the March meeting of the association there had seemed to him to be displayed a lack of knowledge about some of the agents employed in physical therapeutics, especially violet rays and high frequency currents. He gave a history of the discoveries regarding the spectrum from the time of the promulgation of Fraunhofer's lines, and said that all the rays beyond the ultrared on the one hand and the ultraviolet on the other required for their recognition some other medium than the unaided eye, various devices being employed for rendering them visible. A peculiarity of the violet rays was that, while they passed readily through water, quartz, and rock salt, they would not pass through most kinds of glass. The speaker then gave a demonstration of the fluorescence of various substances which responded to the ultraviolet ray, and stated that there were many which did this which failed to respond when exposed to x rays or radium. Thus, there was not a single fluid which would fluoresce under the x ray. One experimenter had alleged that as a result of administering fluorescent solutions internally, and then applying x rays or radium, the tissues are bathed with fluorescent light; but that fluorescent light was developed in the tissues under given conditions, even if a fact, would be exceedingly difficult to demonstrate, and it certainly had not been demonstrated by physical means. Two years ago he had

what their real nature was.

made the discovery of some additional rays. They had been designated by some as the "Piffard rays," but he was free to confess that he did not know

Tesla was entitled to the credit of discovering high frequency currents, but d'Arsonval was the first to devise means for utilizing them in the treatment of disease. It was to be borne in mind that we could have no high frequency currents either from a static machine or a coil without the addition of the Leyden jar. The oscillations of the d'Arsonval currents amounted to fifty millions or more in a second. Having referred to the derived, or shunt, current, the autoconduction, the autocondensation, and other currents, the speaker described the hyperstatic transformer which he himself had devised. In this the d'Arsonval condenser and solenoid were employed, with the addition of a fine wire coil concentric with the solenoid. By means of this current a small malignant growth might be cured instantaneously. The application was intensely painful, but the pain lasted but the fraction of a second.

As to the matter of locomotor ataxia, Dr. Piffard said that there appeared to be a tabes and a pseudotabes, and he did not understand how to tell which was which. The neurological authorities were not agreed as to what the symptom complex of the disease really was.

Dr. LEONARD WEBER said he had found that the present practice at Berlin, Munich, Heidelberg, and other German medical centres in the case of operable cancers was to remove the affected parts as thoroughly as possible with the knife, and then to apply the high frequency current. An intense cedematous reaction followed this, and much necrosed tissue was carried away. As to the question, What is tabes? he had had a good many cases in his practice, and in Germany had seen many hundreds cross sections of spinal cords from tabetics. The sclerosis of the posterior roots and the posterior columns was a metasyphilitic lesion. When an early case presented itself we had to ask ourselves, Is this going to be a classical case of tabes or is it one merely of tabes syphilitica? If the latter, antisyphilitic treatment would be of service, but he had never seen a case of true, classical tabes affected in the slightest degree by such treatment. During the last three months he had been trying some new remedies in tabes, thiosinamine at first and fibrolysine later. These were administered hypodermically, and while the injection of thiosinamine caused some pain, that of fibrolysine did not. He had been induced to employ thiosinamine in this disease by the effects which he had noted from it in old cases of urethral stricture. Thus, in one case of twenty-four years' standing, in which only a filiform bougie could be passed with great difficulty, he was able in two weeks after beginning the hypodermic use of the drug to pass a large sound-No. 26, French. It had occurred to him therefore to endeavor to check the onward march of tabes by these remedies, which seemed to have such a marked effect on cicatricial tissue. Thus far his experience was limited to three cases, all of them instances of classical tabes and of from five to ten years' standing. Up to the present time, no appreciable results had been noted in two of them, but in the third there had been a gratifying improvement. After the sixth injection the lightning pains stopped, and this was for the first time in five years.

Dr. AM ENDE said that he had not found the hypodermic injection of thiosinamine to produce any

Dr. PIFFARD said that what he had desired to find out was how to make a diagnosis before the patient While the pathological lesions were plain enough after death, tabes appeared to be a disease about the origin and nature of which we really knew very little. Neurologists were not at all agreed as to what constituted its essential features. While one would state that the Argyll Robertson pupil was the prime characteristic, another would say that the abolition of the reflexes was, and so on. Then, we wanted something which would check the progress of the disease. While such measures as the Frankel exercises were of much benefit, they were of no value in this respect. It was true, however, that here, as elsewhere, Nature provided a path of safety. We had two kidneys, and two lungs; so that, if one became incapacitated, the other might be depended upon. If, therefore, the progress of this disease could be checked in any way, we could draw to a considerable extent upon our path of safety. effort should be made, he thought, to determine what the essence of tabes really was; and then we should be able to treat it more intelligently.

Diseases Conveyed by Insects.—Dr. John B. Huber read this paper. It would appear, he said, that in the intestines bacteria did not as a rule penetrate the uninjured mucous membrane, but with the aid afforded by certain animalcules which burrowed into the mucosa, and thus made a portal of entry for them, they were enabled to find ingress to the various tissues and organs and produced their characteristic effects. Mord had found that typhoid fever and cholera might be caused in this way. A century ago the whip worm (trichuris), on account of its abundant presence being noted in epidemics of the disease, was looked upon as the cause of typhoid fever; but we know now that its rôle was an intermediary one, though the part that it played in the ætiology was a very important one. Metchnikoff had suggested that appendicitis might originate through the penetration of bacteria into tissues made permeable by intestinal parasites. The intermediaries with which we were at present concerned were insects, and their agency was varied. Thus, the germs might adhere to their bodies, or these might be swallowed by them and either ejected from their mouths or deposited in their fæces upon human food and drink. Or, again, the insects, after eating the germs, might die, and their bodies either fall into food or be disseminated as dust, to be inhaled or swallowed by human beings; or the insects might inject into man disease permeated blood which they had previously sucked from an infected animal.

He spoke first of the common house fly and the way in which it transmitted tuberculosis, the intestinal diseases of infancy, typhoid fever, cholera, and probably tetanus. He had been especially interested in the work done in connection with this subject by Dr. Daniel Jackson in behalf of the Merchants' Association of New York, as presented in their report to Governor Hughes, and also in Dr. Jackson's paper

in the Long Island Medical Journal. Having recapitulated some of the results of these investigations, the speaker said that, while we had long looked upon the house fly simply as a sort of necessary nuisance, it was only recently that we had come to regard it as a dangerous pest. The bacillus of typhoid fever had been found in lice from typhoid patients, and J. P. Mackie had reported an epidemic of relapsing fever in which the pediculus corporis seemed to be a causative factor. This occurred in a mixed settlement of boys and girls living in separate buildings. A very much higher percentage of cases was noted among the boys, who were largely infested with lice, than among the girls, who were almost wholly free from them, and a very considerable proportion of the insects taken from the wards occupied by the boys contained living and multiplying spirilla, the stomach being the chief seat of proliferation. Moreover, with the increase of the epidemic among the girls body lice became more in evidence, while with its subsidence among the boys the percentage of infected lice fell. Mackie noted that in general relapsing fever was commonly met with in poverty stricken, overcrowded, and half starved communities, where lice were apt to be abundant, and that when it occurred in mixed communities the disease seemed to select principally the poor and dirty for its subjects. In the Philippines it had been found that plague might be transmitted from rats to man by means of lice.

He spoke next of the bedbug as a conveyor of disease, especially smallpox. Tubercle bacilli had also been found in the blood of the bedbug, and Metchnikoff believed that the insect formed an intermediate host, or at least an agent, for the trans-

mission of malarial fever. In the acute febrile disease encountered in Montana and neighboring States, known as Rocky Mountain fever and spotted fever, the organism described as its specific germ appeared to be transmitted by the tick, the insect which was the agent of the propagation of the Texas, or cattle, fever. Weber, in a paper in the New York Medical Journal, had described small insects known as psocidæ, which were found in great profusion in barns and outhouses where animals were kept. When a tuberculous cow deposited sputum swarming with bacilli mixed with meal over the woodwork of her stall, these insects would consume this. Weber found microscopic specimens harboring tubercle bacilli, and tuberculous lesions were developed in the peritoneal cavity of guinea pigs as the result of the injection of the material in which the bacilli were found. Possibly typhus fever, leprosy, and other diseases which pre-vailed among squalid and vermin infected people might be transmitted by fleas. Filariasis, a disease somewhat resembling leprosy, had been known to be conveyed to human beings by the mosquito, and the same was true of elephantiasis. Anthrax might be transmitted by means of gadflies or horse flies. Cancer might possibly be an infectious disease, and Webb in a second paper entitled Do Fleas Spread Cancer? had described a case from which he made the following conclusions: 1. The patient was bitten by fleas from the bed of a cancer patient. 2. There followed an inflammation (though not necessarily propter hoc). 3. After about a fortnight a definite growth developed, ending in duct carninoma. The principal charge against the flea, however, was that it was the partner of the rat in the propagation of bubonic plague. The Bacillus pestis existed in rats which were infested with fleas, and the latter conveyed the infection to healthy rats. When the rats died the fleas deserted the bodies for other rats or for human beings. Fleas were really the essential factors in conveying the plague virus to man, and possibly they carried it from sick persons to the well without any intermediate part being played by the rat. The remainder of the paper had to be omitted for lack of time.

Dr. Daniel Jackson said that the curve of typhoid fever in New York differed from that in other places, where the disease was principally due to drinking water, etc., in regard to the time of greatest prevalence. Here this time was in the autumn, two months after the period when flies were most numerous and when the greatest mortality from diarrhœal diseases occurred. His investigations had shown that a large proportion of the cases of typhoid and of summer diarrhœa in infants was attributable to the agency of the fly, and he was convinced that if this cause of transmission could be done away with, a great saving of life would be effected. The flies were propagated principally along the river front, whence they made their way to the neighboring restaurants, and in the centre of certain tenement blocks where the most unsanitary conditions regarding water closets prevailed. The responsibility for the conditions affording such facilities for the multiplication of flies appeared to be more or less divided between the Health, the Tenement House, and the Dock Departments, and he thought that the remedy should be sought in legislative enactment. It would thus be possible to relieve the sewage conditions materially and to do away entirely with the unsanitary conditions in the tenement blocks referred to.

The President said he found that a good many of the phlegmons which were met with at his clinics had their beginning in the bites of fleas or bedbugs.

Book Rotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Applied Physiology. A Manual Showing Functions of the Various Organs in Disease. By Frederick A. Rhodes, M. D., Professor of Physiology and Embryology, Medical and Dental Departments of the Western University of Pennsylvania; Late Physician in Charge to the Reineman Hospital and the Kaufman Clinic; Formerly Assistant to the Chair of Clinical Medicine, West Penn Medical College, etc. Pittsburgh: Medical Press. Pp. 206.

The author has succeeded in making a fairly comprehensive compilation of the leading facts in physiology in their relation to practical medicine. He has been a diligent reader of the works of Krehl, Bunge, Leube, Figerstedt, Hall, von Neusser, and other recent authorities, and has presented the results of his studies in a synoptic form, which may be useful to the beginner if used in connection with, but not to the exclusion of, the larger textbooks

treating the same theme. The difficulty in all books of this class is that most of the facts of medicine and physiology do not admit of such unqualified and categorical presentation, especially the intricate subjects of metabolism, secretion, fever, and the pathology of the central nervous system. There are many evidences of careless proofreading which mar the appearance of the volume and even make the text almost unintelligible at times. The curious definition of digestion as including "those changes which occur in the food from the time that the food is thought of until it is prepared for absorption' would make it appear that the author regards as digestive processes the preparation of food in the kitchen and the unhappy changes it frequenly suffers in cold storage or in the hands of a bad cook.

Ophthalmic Surgery. A Handbook of the Surgical Operations on the Eyeball and its Appendages as Practised at the Clinic of Prof. Hofrat Fuchs. By Dr. Josef Meller, Privatdocent and First Assistant, k. K. II., University Eye Clinic, Vienna. The Translation Reviewed by WALTER L. PYLE A. M., M. D. Member of the American Ophthalmological Society, Ophthalmologist to Mount Sinai Hospital, etc. With 118 Original Illustrations. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. xiii—202 (Price, \$300)

As indicated in the subtitle, this volume considers only the operations of choice, as it were, in the various surgical diseases of the eye. Accordingly we note that a large number of ophthalmic operations are, naturally, not described at all. The work is, however, an excellent guide, and is a welcome addition to the literature on the subject. is a good teacher and demonstrator, and the style of the work, both in a literary and a scientific sense, is very good. The illustrations in half tone after very artistic wash drawings are unusually fine and on such a scale that every step of the various eye operations is made clear. Meller also considers a number of recent innovations in ophthalmic surgery, and concludes with an extremely interesting and instructive chapter on minor operations, anæsthesia, and the duties of the assistant.

The Executive Practice in Diseases of Children By WILLIAM NELSON MUNDY, M. D., Professor of Pædiatrics in the Eelectic Medical Institute, Cincinnati, O. Second Revised Edition, Illustrated, Cincinnati: The Scudder Brothers Company. Pp. 512. (Price, \$3.)

The arrangement of this work is similar to that of most books on pædiatrics, but the classification is in some respects peculiar. Pharyngitis, adenoid growths, and amygdalitis are considered under diseases of the digestive apparatus, while larvngitis is included under diseases of the respiratory apparatus. Diabetes is classed as a disease of the genitourinary organs, and curvature of the spine as a disease of the nervvous system. The grammar leaves much to be desired. Future editions would be improved by consultation with an expert grammarian. While treatment receives important attention, the book is a genera! work on the diseases of children. In the chapter on diphtheria, the uses of aconite, belladonna, gelsemium, and thirteen other drugs are described in detail. "Diphtheria being a disease of the blood," says the author, "the treatment will in all cases be general, with attention to local treatment in severe throat complications. The primary objects are to sustain the strength of the patient so as to enable

him to combat the effects of the toxæmia, and to limit the production and extension of the exudation." Six lines are devoted to antitoxine, which, the author says, has revolutionized the treatment of diphtheria. Nothing whatever is said as to its use, administration, or dose. The illustrations, though not numerous, are good, but are borrowed in almost every instance from other textbooks. The sections on infant feeding are also borrowed largely, the works of Holt, Rotch, Koplik, and Chapin being largely drawn upon. Less than a page is devoted to maternal nursing, and the section on artificial feeding is inadequate. In fact, the same may be said of the book as a whole as a working guide upon pædiatrics for the general practitioner.

A Textbook of Discases of Women. By Charles B. Penrose, M. D., Ph. D., formerly Professor of Gynæcology in the University of Pennsylvania, etc. With 225 Illustrations. Sixth Edition, Revised. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 550.

The new edition of this standard treatise will be welcomed alike by specialists, general practitioners, and students. The revision has been interstitial, but the book has been well brought up to the teaching of the present time. Dr. Penrose's textbook is sure to maintain its popularity with the profession for many years to come.

Lehrbuch klinischer Untersuchungsmethoden für Studierende und Aerzte. Von Dr. Theodor Brugsch, Assistent der II. mediz. Universitäts-Klinik in Berlin, und Dr. Alfred Schittenhelm, a.o., Professor der inneren Medizin in Erlangen. Mit emem Beitrag: Klinische Bakteriologie, Protozoologie und Immuno-Diagnostik, von Dr. J. Citron, Berlin. Mit 341 Textabbildungen, 5 schwarzen und 5 farbigen Tafeln. Berlin und Wien: Urban & Schwarzenberg, 1908. Pp. 939.

The many branches of medical science have made such progress during the last twenty-five years that an up to date book on diagnostics must necessarily be of great volume. There are so many major and minor details which have to be taken into consideration, not only in simple, but also in distinctive diagnosis, and the methods for determination are so manifold, that diagnostics has become a science of its own

The authors have taken all this into consideration and have compiled a very valuable book, which somewhat deviates from the current textbook, as Dr. Brugsch and Dr. Schittenhelm base their clinical diagnosis upon researches of the pathological physiologist. It begins with a description of the general examination of the patient, his own statement, his appearance, the external condition of his body, such as the skin, the thyreoid, the temperature, topography, etc. This is followed by percussion and auscultation, manual and instrumental examination of the heart and the bloodvessels, and the detailed examination of the organs of respiration. Examination of fluids obtained by paracentesis and puncture and the use of Röntgen rays for diagnostic purposes are mentioned next. Then follows the physical diagnosis of diseases of the heart, vessels, and lungs. The next chapters contain the diagnosis of the apparatus of digestion, of the kidney and urine, and of the pathology of metabolism. The technique of the examination of the blood is well treated. Dr. Citron is the author of the chapter on diagnosis from the point of view of bacteriology, protozoology, and

immunization. The nervous system is treated of in the last chapter. From this short synopsis it may be seen that the authors have treated the subject thoroughly.

Guide to the Clinical Examination and Treatment of Sick Children. Second Edition, Greatly Enlarged and Rewritten. By John THOMSON, M. D., F. R. C. P. Ed., Physician to the Royal Edinburgh Hospital for Sick Children, etc. With 160 Illustrations. Edinburgh and London: William Green & Sons, 1908. Pp. xxviii-629. (Price, 128. 6d.)

This edition of Dr. Thomson's work is more than twice as large as the first one, and it is very comprehensive. It deals eminently with practical matters, the clinical aspects of children's diseases being given prominence and questions of pathology subordinated so far as is compatible with satisfactory treatment from the practitioner's point of view. We regard it as among the best of the less bulky treatises on pædiatrics. It evinces on the part of the author great experience, exceptional powers of observation, and the wisdom and kindliness of the ideal physician. It deserves to maintain a high place in the esteem of the profession. The illustrations are particularly effective, and the entire mechanical appearance of the book is most creditable to the publishers.

Diet in Infancy. The Essential Introduction to the Study of Disease in Childhood. By A. DINGWALL-FORDYCE, M. D., F. R. C. P. Ed., Extra Physician to the Royal Hospital for Sick Children, Edinburgh. Edinburgh and London: William Green & Sons, 1908. Pp. x-174. (Price, 3s. 6d.)

In the preface the author says of his little book: "It pretends to no heights of eloquence and no profound depths of scientific information. It aims at being of practical utility to practical men working among children." We think he has succeeded in making such a book as he thus indicates. Much of its teaching is in a line with what our American pædiatrists have inculcated for years. We commend the book to students and young practitioners.

Cancer. Par P. MENETRIER, Professeur agrégé à la Faculté de médecine de l'Hôpital Tenon. Avec 114 figures intercalées dans le texte. Paris: J. B. Baillière et Fils, 1909. Pp. 662.

The author reviews briefly the history of cancer, which he defines as characterized clinically by a local tumor, superficial or deep, according to the organ in which it is developed, and which progressively invades and poisons the entire organism. It is not a disease, but a morbid process-that is, a process of autoinfection of the organism by the cells of the organism, proliferating cells, invading and destroying the normal elements with which they come in conflict. All the cellular elements of the organism are eventually capable of such pathogenic activity, exactly in proportion as they are capable of regenerative, irritative, or compensatory proliferation, and hyperplasia, which are normal functions from which the cancerous process represents a pathological deviation.

He gives a careful general description of the cancerous process, the cancer cell and its modes of multiplication, its morphology and general biology, its functions, secretions, and degenerations, its chemistry, and its experimental biology. He reviews the morbid states antecedent to the development of can-

cer, its beginning, growth, and primary extension, its metastasis, its regression, its general action on the organism, and its clinical evolution and diagnosis

He adopts the simple classification of cancers that develop at the expense of the epithelial tissues; cancers that develop at the expense of the vasculoconnective tissues; and tumors from several tissues and their neoplastic derivatives. Each of these classes is described in detail, as are the several theories of the pathogenesis of cancer and the various methods of treatment. There are excellent illustrations of microscopical sections, and the volume affords an admirable presentation of our knowledge of cancer.

The Law in General Medical Practice. Some Chapters in Every Day Forensic Medicine. By STANLEY B. ATKINSON, M. A., M. B., B. Sc., of the Inner Temple, Barrister at Law, Justice of the Peace for the County of London, Member of the Central Midwives' Board, Hon. Secretary of the Medicolegal Society (London). London: Henry Frowde and Hodder & Stoughton, 1908. Pp. viii-239.

This book can hardly be called a treatise on the law, as its title suggests. In eight entertaining chapters the author offers much of fatherly advice to young doctors and some very practical suggestions which might prove of value to the experienced practitioner. The book is written mainly for English circulation, and the chapters on Medical Certificates and Reports, and on Cases Arising in the Coroner's Court, are based wholly upon the English statutes, but the law quoted here and there by the author as to medical evidence, medical witnesses, negligence, and malpractice is generally the law of the United States as well as of the United Kingdom, decisions of the courts of our various States being quoted in numerous instances. The author's style is breezy-almost jocular.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Taber's Pocket Encyclopædic Medical Dictionary. Edited by Clarence W. Taber, Author of Taber's Medical Dictionary for Nurses, etc. Associate Editor, the late Nicholas Senn, M. D., Ph. D., L.L. D., C. M. Chicago: C. W. Taber, 1908. Pp. x to 13-418.

On Infantilism from Chronic Intestinal Infection. Characterized by the Overgrowth and Persistence of Flora of the Nursing Period. A Study of the Clinical Course, Bacteriology, Chemistry, and Therapeutics of Arrested Development in Infancy. By C. A. Herter, M. D., Professor of Pharmacology and Therapeutics, Columbia University. New York: The Macmillan Company, 1908. Pp. 118. (Price, 90 cents.)

Arteriosclerosis: Ætiology, Pathology, Diagnosis, Prognosis, Prophylaxis, and Treatment. By Louis M. Warfield, A. B., M. D., Instructor in Medicine, Washington University, Medical Department, etc. With an Introduction by W. S. Thayer, M. D., Professor of Clinical Medicine, Johns Hapkins University. Eight Original Illustrations. St. Louis: C. V. Mosby Medical Book Company, 1908. Pp. xvii-105.

Miscellany.

William Whitfield Miller .- While stationed at the Hygienic Laboratory in Washington, D. C., Assistant Surgeon William W. Miller contracted typhoid fever and died in Providence Hospital, November 24, 1908, after an illness of eight weeks.

William Whitfield Miller, son of William Whitfield and Mary Mebane Miller, was born at Water Valley, Miss., June 26, 1880. When he was five years of age his parents moved to Memphis, Tenn. Here he attended private schools, and later completed his preliminary education in the University of Virginia, where he won the Miller scholarship for excellence in biology. He then studied medicine in the Medical Department of that institution, and received the degree of doctor of medicine in 1901. After graduation he took a special course in pathology at Harvard University. Later he went to New York and was assistant in bacteriology in Columbia University, and assistant pathologist in Roosevelt Hospital. Subsequently he served for two years on the resident staff of that hospital. In 1905 he returned to Memphis, engaged in private practice, and was demonstrator of pathology at the College of Physicians and Surgeons in that city

After passing a brilliant competitive examination, Dr. Miller was commissioned an assistant surgeon in the United States Public Health and Marine Hospital Service September 4, 1906, and assigned to duty at the Immigration Station, Ellis Island, New York. In August, 1907, he was relieved from Ellis Island and assigned to the Hygienic Laboratory of the Public Health and Marine Hospital Service, Washington, D. C. At the laboratory he made examinations of such pathological specimens as were

sent in for diagnosis.

In connection with the investigation of the origin and prevalence of typhoid fever in the District of Columbia he made many of the bacteriological examinations of water and milk, and during the last summer made over a thousand bacteriological examinations in the search for bacillus carriers. His training and equipment for research work enabled him to take up original problems. He discovered a pathogenic hæmogregarine in the blood of white rats, described its life cycle and the mechanism of infection by the digestive tract. A preliminary note of this discovery was published in the weekly Public Health Reports, July 24. 1908. The completed work forms Hygienic Laboratory Bulletin, No. 46.

Dr. Miller was married in 1906, and leaves a widow and infant daughter. Personally he was modest, had an exceptionally winning and lovable disposition, and commanded the respect and affectionate regard of those with whom he was intimately associated. His untimely death terminated a career which had already given promise of a bril-

liant future.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commis-sioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending

BILLINGS, W. C., Passed Assistant Surgeon. Bureau orders of November 3, 1908, detailing him for duty on the Revenue Cutter Itasca, amended, detailing him for duty at the Revenue Cutter School of Instruction, Arundel Cove, Md.

COBB, J. O., Surgeon. Granted fifteen days' leave of absence from December 22, 1908. Cofer, L. E., Passed Assistant Surgeon. Directed to report to Director Hygienic Laboratory for temporary

duty.

Cofer, L. E., Passed Assistant Surgeon. Granted four days' leave of absence from December 1, 1908 under paraggraph 191, Service Regulations.

CORPUT, G. M., Passed Assistant Surgeon. Granted ten
days' leave of absence from December 8, 1908.

DUKE, B. F., Acting Assistant Surgeon. Granted twenty-three days' leave of absence from November 23, 1908. FOSTER, ALBERT D., Passed Assistant Surgeon. Relieved from duty on the Revenue Cutter Thetis; directed to proceed to Angel Island, Cal., and report to command-

ing officer for temporary duty.

Gustetter, A. L., Acting Assistant Surgeon. Granted six days' extension of leave of absence from November

26, 1908.

LAGRANGE, J. V., Pharmacist. Granted thirty days' leave

of absence from November 3, 1908.

LANZA, A. J., Assistant Surgeon. Relieved from duty on the Revenue Cutter Rush; directed to report to com-Relieved from duty on manding officer of the Revenue Cutter McCulloch, for duty.

OLESEN, ROBERT, Assistant Surgeon. Upon being relieved by Assistant Surgeon A. J. Lanza, directed to proceed to Marine Hospital, San Francisco, Cal, and report to commanding officer for temporary duty.

Stoner, J. B., Surgeon. Directed to proceed to Louisville,

Ky., Cairo, Ill., and Memphis, Tenn., upon special tem-

Ky., Carro, Hi., and Assistant Surgeon. Leave of porary duty.

Thompson, W. R. P., Acting Assistant Surgeon. Leave of absence for thirty days from November 23, 1908, granted November 11, 1908, revoked November 27, 1908.

Board of medical officers convened to meet at the Marine Hospital, Baltimore, Md., December 2, 1908, for the reexamination of a cadet of the U. S. Revenue Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; Passed Assistant Surgeon J. W. Schereschewsky, recorder.

Casualty.

Assistant Surgeon W. W. Miller died in Washington, D. C., November 24, 1908.

Army Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Army for the week ending December 12, 1908:

Brewer, I. W., First Lieutenant, Medical Reserve Corps.
When relieved from duty at Fort Warren, Mass., ordered to San Francisco, Cal., and thence to sail for service in the Philippine Islands.
Byrne, C. B., Colonel, Medical Corps. Ordered to report before an Army retiring board at Washington, for ex-

W., First Lieutenant, Medical Reserve Corps. TOHNSON, C. Ordered from Fort Des Moines, Ia., to Fort Meade, S. Dak., for temporary duty. KENDALL, W. P., Major, Medical Corps. Granted leave of

KIERSTED, H. S., Captain, Medical Corps. Granted leave of absence for one month, to take effect about December 15, 1908, with permission to apply for an extension of fifteen days.

KULP, JOHN S., Major, Medical Corps. Retired from active

service on account of disability.

18, W. F., Major, Medical Corps. Relieved from duty at Fort Sill, Okla., and ordered to Fort Thomas, Ky., for duty.

MOUNT, J. R., First Lieutenant, Medical Reserve Corps.

Leave of absence revoked.

Nichots, H. J., First Lieutenant, Medical Corps. Granted leave of absence for two months, upon arrival in the

United States.

PIERSON, R. H., Captain, Medical Corps. Ordered from Fort Niagara, N. Y., to Fort H. C. Wright, N. Y., for

PINKSTON, O. W., First Lieutenant, Medical Corps.

PINKSTON, O. W., First Lieutenant, Medical Corps. When services are no longer needed on the transport Crook, ordered to Hot Springs, Ark., for duty at the Army and Navy General Hospital.
 SMITH, R. D., First Lieutenant, Medical Reserve Corps. Relieved from further duty in the Philippines Division, Sparkenberger, F. H., First Lieutenant, Medical Reserve Corps. Relieved from duty at Fort Washakie, Wyo., and ordered to Fort Warren, Mass., for duty.

TRUBY, A. E., Major, Medical Corps. Detailed a member of an examining board at San Francisco, Cal., vice Colonel G. H. Torney, relieved.

WORTHINGTON, J. A., First Lieutenant, Medical Corps. Assigned to duty on the transport Thomas, instead of the

transport Crook.

Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the week ending December 12, 1908:

CARPENTER, D. N., Surgeon. Ordered to the Naval Acad-

Casto, D. H., Assistant Surgeon. Detached from the Sup-ply and ordered to continue duty at the naval station, Guam, M. I.

Downey, J. G., Assistant Surgeon. Detached from the Relief and ordered to the Charleston.

EYTINGE, E. O. J., Assistant Surgeon. Detached from the

EYTINGE, E. O. J., Assistant Surgeon. Detached from the Ranger, when placed out of commission, and ordered to duty at the Naval Hospital, New York, N. Y. GEIGER, A. J., Passed Assistant Surgeon. Detached from the Supply and ordered to continue duty at the Naval Station, Guam, M. I. MUNSON, F. M., Passed Assistant Surgeon. Ordered to the Monadnock and to the Monterey, when discharged from treatment at the Naval Hospital, Canacao, P. I.

Thomas, G. E., Acting Assistant Surgeon. Appointed an acting assistant surgeon from December 3, 1908.

Warner, R. A., Passed Assistant Surgeon. Detached from the Naval Academy, and ordered to duty at the Naval Hospital, Norfolk, Va.

Births, Marriages, and Deaths.

Brown—Zell.—In Philadelphia, on Wednesday, December 9th, Dr. C. Morse Brown, of Cambridge, Mass., and Miss Anna Vendette Zell.

CAIRNS—TOWNE—In New York, on Wednesday, December 9th, Dr. Douglas Walker Cairns and Miss Rose

Ethel Towne.

Cornwell—Johnson.—In New York, on Wednesday, December 16th, Dr. Frank Wilbur Cornwell, of Plainfield, N. J., and Miss Elizabeth Fairiax Johnson.
Meitzner—Elsele.—In Jersey City, N. J., on Wednesday, December 2d, Dr. Max Meitzner, of Philadelphia, and Miss Bertha Eisele.

BAKER.—In Brooklyn N. Y., on Friday, December 11th, Dr. Frank Russell Baker, aged thirty-nine years.
BATES.—In Chicago, on Thursday, December 3d, Dr. J.

BATES.—In Chicago, on Thursday, December 3d, Dr. J. Harvey Bates, aged thirty-six years.

BICKNELL.—In Omaha, Nebraska, on Saturday, November 28th, Dr. George H. Bicknell, aged forty-four years.

CRAIG.—In Griffithsville, West Virginia, on Tuesday, November 24th, Dr. Harvey F. Craig, aged forty-eight years.

DAVIDSON.—In Fresno, California, on Monday, November 30th, Dr. J. D. Davidson, aged forty-six years.

DOD.—In Newark, New Jersey, on Sunday, December 6th, Dr. Bethuel Lewis Dodd, aged eighty-three years.

Gibbs.—In Newport, Rhode Island, on Wednesday, December 9th, Dr. Oliver Wolcott Gibbs, aged eighty-six

cember 9th, Dr. Oliver Wolcott Gibbs, aged eighty-six

MATTHAEL.-In Sierra Madre, California, on Saturday,

MATTHAEL—In Sierra Madre, California, on Saturday, December 5th, Dr. Ernest A. Matthaei, of Chicago. MAY.—In Black River, Louisiana, on Thursday, November 26th, Dr. Green Berry May, aged eighty-two years. OsGood.—In St. Louis, Missouri, on Thursday, December 3d, Dr. Mary L. Osgood, aged sixty years. Prits.—In Hazlehurst, Mississippi, on Thursday, December 10th, Dr. A. B. Pitts.

Reed.—In Cambridge, Massachusetts, on Wednesday, December 2d, Dr. Guilford Shaw Reed, aged seventy-one

Root.-In De Kalb, Illinois, on Thursday, November

26th, Dr. Edith A. Root. St. History D. L. Montreal, an Monday, October 5th, Dr. John Sutherland, of Bedeque, P. E. I., aged sixty-two

years. Whittie: In Charlan, N. V. on Thursday, December 3d, Dr. John T. Wheeler, aged fifty-eight years.

THE INFLUENCE OF ALCOHOL UPON THE PUBLIC HEALTH.*

By Frederick Peterson, M. D., New York,

Professor of Psychiatry, Columbia University; Ex-President of the New York State Commission in Lunacy; Manager of the Craig Colony for Epileptics.

The mysterious power which has led mankind through all these ages from the protozoon up to man, through combat and struggle with the elements, with natural enemies, with disease, always to give us, at the proper moment, when it is most needed, the means of rescue, the power of triumph. So in these later years, when physical structure has been safeguarded and more or less perfected, and there is need of speedier spiritual growth and development, that same power sows in a million minds the seeds from which spring freedom, social reform, moral uplifting, greater knowledge of the uses of the matter and forces all about us, and warnings of whatever may endanger the progress of the human race. Thus it must be that practically at the same moment all over the world, in Great Britain, Scandinavia, Germany, France, Italy, the United States, there has arisen a wave of feeling against the misuse of alcohol.

It is true that whenever a child is born the forces of Nature bear down upon it with all the hereditary impetus of a hundred million years to make and keep it a normal average. But it is also true that there are powerful factors which may deflect and pervert this hereditary tendency to a normal average, and these factors are such as affect the nervous system, diseases and poisons. Insanity and epilepsy are among the diseases that taint our progeny. Alcohol is the chief poison that has this baneful power. As an example of what one individual may do I might cite the oft quoted Jukes family in the State of New York. One hard drinker was the originator of this family, which, over a generation ago, when Dugdale wrote his book, had become already 1,200 in number. In his summary of the study of the Jukes family of degenerates the author says:

"Over a million and a quarter dollars of loss in seventy-five years, caused by a single family, 1,200 strong, without reckoning the cash paid for whisgenerations, and the incurable disease, idiocy, and insanity growing out of this debauchery, and reaching further than we can calculate."

This is one family.

In the State of New York there are now some

key, or taking into account the entailment of pauperism and crime on the survivors in succeeding

In the State of New York there are now some 30,000 insane in the public and private hospitals, and it is estimated that twenty per cent. of these, or 6,000 patients, owe their insanity to alcohol. In all the asylums of the United States there are 150,000 insane, and assuming the same percentage, there are 30,000 individuals in this country in whom alcohol has brought about insanity. Dr. MacDonald calculates that one insane person is an approximate loss to the State of \$400 per year. Hence the actual loss in money to the State of New York through alcoholic insanity is \$2,400,000, and to the United States \$12,000,000 every year.

Alcohol is often a direct cause of epilepsy, but more often epilepsy is due to alcoholism in parents. Thus Bourneville, in a study of over 2,500 idiots, epileptics, and imbeciles admitted to the Bicêtre Hospital, found that over forty-one per cent. of them had drunken parents. In the report of the Craig Colony for epileptics it was found that over twenty-two per cent. of 950 cases of epilepsy had al-

coholic parents.

There is not time here to take up the subject of the relation of alcohol to pauperism and crime. But what I want to point out is that the asylums for the insane, the institutions for epileptics, idiots, and feebleminded, the prisons and the county poorhouses, are representative as far as their alcoholic indulgence and debauchery. Here alcohol has done it worst to the living individual. Below this topmost wave of ruin and desolation are innumerable gradations of alcoholism down to the moderate drinkers and the temperate or occasional drinkers.

The race is reasonably safe from further contamination by those victims of alcohol who are locked away in the retreats that our charitable world provides for them. It is otherwise with the vaster number of excessive drinkers, who are free to work any havoc in the social organism and who are direct and indirect feeders of the institutions named. What these may do to themselves and their wives and their children and their children we have come to learn, and it is because of this awakening to a common danger to the human race that the nations of the earth are combined in a common campaign.

^{*}Read before the ninth New York State Conference of Charities and Correction, Elmira, November 17, 1908.

It is not a single Jukes family that society has ranged itself against, but against the legions of Jukes families that menace the human stock.

It is because physicians have been brought into contact with this destructiveness that they are leaders everywhere in the great crusade. They feel themselves to be the guardians of the health of the racial mind and body. Just as they fight tuberculosis and typhoid fever and many other infectious diseases, so do they array themselves against the dangerous agent that crowds the hospitals, prisons, and almshouses with its countless victims. may differ among themselves upon minor points, such as whether alcohol has any nutritive value, whether it should ever be used as a stimulant in sickness, whether moderate drinking is always harmful, but the medical profession is at one in its stand against that abuse of alcohol which leads to the wrecking of the home and race degeneracy. The question of the harmfulness of drink has grown more acute to medical men of late years, for with the wonderful progress of their science in all departments, this too has had its share of scientific study and investigation, from the clinical, pathological, and experimental standpoints. The evidence thus accumulated in the past twenty to thirty years has established so many convincing facts that medical men are aroused as never before to the need of restricting the sale of alcoholic beverages, and of teaching the public the facts they have come to know. They all agree that alcohol is a poison, taken in any form-beer, wine, hard cider, rum, whiskey, bitters, or patent medicines. There is no question as to its being a poison.

The retort that the active principles of tea and coffee are also poisons is no argument in favor of alcohol, for while taken in excess tea and coffee do induce certain mild nervous disorders, these are insignificant when compared with the unparalleled de-

structiveness of drink.

The discussion as to whether alcohol is ever a food is equally idle and evasive of the main issue. It is not a food like bread and butter, for it has venom in it. As Professor Abel, of Johns Hopkins University, says, "it is an easily oxidizable drug with numerous untoward effects which inevitably appear when a certain minimum dose is exceeded." I have italicized the word drug, because it is as a drug that alcohol is now regarded by most physicians. It is placed among the narcotics and anæsthetics.

I should like here to present a very brief summary of what scientific investigators have recently determined to be the action of this drug:

It is no longer considered to be a stimulant, but rather a depressant.

It perverts digestion.

It depresses and weakens the heart action.

It decreases the capacity to do muscular work.

It diminishes the intellectual functions, by dulling the creative faculty, impairing judgment, vitiating the correctness of perceptions, and by generating timidity.

It brings about slow, far reaching anatomical changes, such as fatty degeneration of the heart, kidney disease, diseases of the bloodvessels, changes in the muscular tissues and in the cells and fibres of the nervous system.

Its habitual use lessens the normal defenses of the organism against infectious diseases, especially tuberculosis.

In this connection I cannot do better than commend to your attention the extremely able article on Alcohol and the Individual, by Dr. Henry Smith Williams, in *McClure's Magazine* for October, in which all the best authorities are quoted in *extenso*. It is the most complete résumé of our scientific knowledge of the subject that has yet appeared.

With such an array of fact and authority before you, you will readily understand the position of physicians on this subject, and why they are the leaders in the antialcoholic crusade. They can hardly be thought to be either fanatical or hysterical in their propaganda. You cannot question the honesty or disinterestedness of their motives. If, however, you find here and there some dissenting voice, that of some university professor perhaps, you may be sure that it is not that of a person with medical experience or any one familiar with the material which all may read, but rather the voice of some one perversely interested. You might well question whether such an one is simply seeking sensational exploitation of himself or whether he might not even be subsidized by the vast commercial interests at stake, for you must remember that the annual consumption of alcoholic drinks in the United States is over a billion gallons.

The alcohol problem is so interwoven with our whole modern life, with politics, with industries, with government revenues, as a source of wealth, etc., that it affords matter for many sided discussion. But here we are only concerned with public health, and it is from that standpoint that I present the subject to you. I believe that human evolution has now reached the stage when the abolition of the use of alcohol as a beverage is expected and required. Abstinence is one of the principles of human eugenics, that new science that is just being horn.

There is no one here present who would feed alcohol to his dogs, horses, sheep, or cattle. These possessions are too precious for that. He is too much interested in improving their breed. He would recall Professor Hodge's experiment with alcoholized dogs, in which among twenty-three pups born in four litters to one pair of alcoholized dogs, nine were born dead, eight were deformed, and only four apparently normal.

Our best method of eradicating the alcoholic evil is that of a campaign of education. Every man, woman, and child should be made familiar in one way or another with what is known by the medical profession of the ravages of alcohol. The main facts in some brief form should be brought home to them. For instance, in Paris they put up a poster in every public hospital ward and on every prescription blank of their hospitals and dispensaries they print the following:

Alcoholism: Its Dangers.

Alcoholism is the chronic poisoning which results from the talatival use of alcohol, even if not used to the extent of producing drunkeiness. It is an error to say that aleohol is necessary to laborers occupied with fatiguing work, that it gives heart for work or renews their strength; the artificial excitement produced by it rapidly gives place to nervous depression and weakness. In reality alcohol has

no actual use for anyone.

The habit of drinking strong liquors leads rapidly to alcoholism; but the drinks called hygienic (in France) also contain alcohol, the difference being only in the dose. The man who drinks daily an immoderate quantity of wine, cider, or beer becomes alcoholic also, as well as he who drinks the stronger liquors.

The drinks labelled as aperitive (in France), such as absinthe, vermouth, and bitters, and the aromatic liqueurs are more pernicious because they contain, in addition to alcohol, essences which are themselves also violent poisons. The habit of drinking leads to family disaffection, the

forgetting of all social obligations, disgust with work, pau-

perism, theft, and crime.

This habit leads ultimately to the hospital, for alcoholism engenders the most various and destructive diseases— paralysis, insanity, disorders of the stomach and liver, dropsy. It is one of the most frequent causes of tubercudropsy. It is one of the most frequent causes of tubercu-losis. Furthermore, it complicates and aggravates acute diseases; typhoid fever, pneumonia, erysipelas, which run benignly in a sober man quickly kill the drinker.

The faults of the parents fall upon their children. If these live beyond the first months, they are menaced with idiocy, epilepsy, or later fall victims to tuberculous menin-

gitis or consumption.

For the health of the individual, for the existence of the family, for the future of the country, alcoholism is one of the most terrible dangers.

These statements of the French hospital posters could be made even more brief, as I have myself made them for use on my own prescription blanks as follows:

Alcohol is a poison. It is claimed by some that alcohol is a food. If so, it is a poisoned food.

The daily regular use of alcohol, even in moderation,

often leads to chronic alcoholism. One is poisoned less rapidly by the use of beer than by

drinking wines, gin, whiskey, and brandy.

Alcohol is one of the most common causes of insanity, epilepsy, paralysis, diseases of the liver and stomach, dropsy, and tuberculosis.

A father or mother who drinks poisons the children born to them, so that many die in infancy, while others grow up as idiots and epileptics.

These rules go but a little way, to be sure, but if the 132,000 physicians in the United States could be induced to do likewise, they might help a little to persuade some of the 198,669 saloonkeepers, bartenders, brewers, maltsters, distillers, and rectifiers in this country of the harmfulness of their trades.

Somewhere in one of his books Maeterlinck observes that if the human race were to give up meat and alcohol there would no longer be hungry people.

At any rate, a study of the twelfth census of the United States for 1900 is an interesting commentary upon Maeterlinck's suggestion. I find there among the "industry groups ranked by capital," after iron and steel and their products, the textiles, lumber and its manufacture, and paper and printing, that the industries of food and kindred products are capitalized at \$938,000,000, and those of liquors and beverages, \$534,000,000.

It is easy to see that if the \$0,38,000,000 capital in the food industry can supply the greater part of the food necessary for our nation's use, the \$534,000,-000 of capital worse than wasted on the industries of poisonous drinks might well feed all the hungry

and still leave a handsome surplus.

HYDROCEPHALUS.

By S. D. LUDLUM, M. D., Philadelphia,

Instructor in New dogy and New y Pennsylvania. wath dogy. University of

(From the Aver Chineal Laborator). Penns visua II spec-from the Department of Neurology and the Laboratory of Neuropathology of the University of Pennsylvania.)

The various writers upon hydrocephalus do not agree upon many points, and therefore the subject is still open for discussion. This paper records two cases of internal hydrocephalus in which were definite lesions causing the condition, both in the aqueduct of Sylvius, one following tuberculous meningitis, and the other the epidemic form of meningitis. By means of the foramen of Magendie and the two lateral apertures in the fourth ventricle, the system of ventricular cavities and the central canal of the spinal cord are brought into communication with the subarachnoid lymph space. The fourth ventricle drains the third by the aqueduct of Sylvius, and the third communicates with the lateral ventricles by the foramina of Monro. A path is thus provided by which the cerebrospinal fluid secreted within the ventricles by the various choroid plexuses constantly escapes, and thereby prevents undue accumulation and distension within the cavities of the brain and spinal cord. Any one of these passages is open to infective processes.

Bramwell reports the closure of the foramen of Magendie from meningitis with consequent hydrocephalus. Neurath (Neurologisches Centralblatt, 1896, p. 87) also reports a closure of the foramen of Magendie. There does not seem to be any report of search into the condition of the lateral apertures flanking the foramen of Magendie. But there are a few cases reported of involvement of the aqueduct of Sylvius. Dixly (Neurologisches Centralblatt, 1899, p. 977) has studied internal hydrocephalus in the horse, and thinks it is due to occlusion of that passage. Bourneville and Novy (Le Progrès médical, 1900, July 14) report chronic hydrocephalus in a child, with the aqueduct of Sylvius completely obliterated. Jouche (Bulletins et mémoires de la Société médicale des hôpiteaux de Paris, 1902, No. 7. p. 141) has reported a case of hydrocephalus with the aqueduct of Sylvius obliterated. Spiller (American Journal of the Medical Sciences, July, 1902) has put on record a case of internal hydrocephalus resulting from closure of the aqueduct of Sylvius by proliferation of the neuroglia. Spiller and Allen (Journal of the American Medical Association, April 13, 1907) report a case of partial occlusion of the aqueduct, probably due to congenital mulformation. It is not in any way a new observation, but the cases accurately reported are about as stated. Hydrocephalus due to occlusion of one or both foramina of Monro has been reported by W. C. White (Journal of Insanity, Iviii, No. 3), unilateral; and by Spiller, Unilateral Hydrocephalus Due to Partial Closure of the Right Foramen of Monro, in *The American Journal of the Medical Sciences*, July. 1902. Most of these cases were examples of chronic

^{&#}x27;In Obersteiner's Festschrift Dr. Spiller recorded another case of contail the against the Selvers to exceed another calculated upward movements, and has marked the case in which the constraints

hydrocephalus. Both of the cases appended in the article were acute secondary closures of the aque-

duct of Sylvius following meningitis.

Quincke describes an idiopathic internal hydrocephalus as an ependymitis causing a serous effusion and pressure effects, which might be compared to the serous exudates in the pleura or synovial membranes. It is hardly an inflammatory process, and Quincke likens it to an angeioneurotic ædema. This is termed an ependymitis, but in acute cases the ependyma is smooth and natural looking, and in chronic cases is thick and sodden. In most of the cases the choroid plexus is enlarged and congested.

Among 1,180 insane patients at the Norristown State Institution, Pennsylvania, there were 337 cases with dilatation of lateral ventricles; the majority of these showed swelling and cystic involvement of the choroid plexus, but not nearly such a large proportion have noticeable involvement of the ependyma. The cases were of the ordinary forms of insanity

with these conditions found at necropsy.

The inference is that the increase of fluid is due to the choroid plexus, that it is blocked, and more than a normal quantity of fluid secreted. Hyaline bodies forming among vessels would do this, and they are commonly reported. Burr and McCarthy, in a paper in The Journal of Experimental Medicine, 1899, from the result of experimental toxic injections, show that the condition of the ependyma in a case of acute hydrocephalus is similar to a toxic condition of the ventricular fluid. This fact also being in favor of the choroid plexus being the important factor of the disorder, and not an ependymitis. Engorgement of the choroid plexus would shut up the foramina of Monro and this could cause lateral hydrocephalus. The inflammatory condition of the plexus with its ensuing exudate could furnish the fluid, or, as has been said, a retardation of blood flow by hyaline bodies in the vessels causing increased transudate; and the thickened condition of the ependyma be due to pressure of fluid or the retention of the fluid becoming more and more toxic.

The characteristic composition of the cerebrospinal fluid-viz., a low percentage of albumin and a high percentage of potassium salts-shows that it is not an ordinary transudate, but a secretory product from certain cells, probably those of the choroid plexuses. (Falkenheim and Nauryn, Archiv für experimentelle Pathologie, xxii, p. 269). The resorption of this fluid takes place mainly in the Pacchionian bodies and to a lesser extent in the neighboring lymphatics. A meningitis would impede this resorption, production increased and absorption diminished. So the primary change in Quincke's type may be in the choroid plexus, with secondary action upon the ependyma and in the acute meningitic forms due to closure of one or more foramina.

Alcoholism on the part of parents is supposed to play a part in hereditary hydrocephalus. Trau-matism after birth seems to have produced certain cases. But all cases would seem to centre upon patency of openings and amount of secretion from the choroid. External hydrocephalus can usually be explained by atrophy of the brain substance, met with in old age, after hæmorrhage, softenings, or sclerosis in lingering or cachectic diseases. Hydrocephalus due to brain growths is quite obvious in certain cases and needs no comment.

Case I.—Dr. Henry Hutchinson's Case: The patient was taken to the Pennsylvania Hospital with fever, there developed stiffness of the neck, Kernig's sign; with this there were absent knee jerks and abolished Achilles reflexes. Pupils were equal and reacting sluggishly to light. Lumbar puncture showed in smears the diplococcus intracellumbar. laris of Weichselbaum. Leucocyte count was 19,000. Lumbar puncture at two successive times showed an improvement as the case progressed. Then the ears began suppurating, the condition of the patient became worse, and eventually death ensued at the end of seven weeks of

A. (871), C. R. Autopsy was performed by Dr. Robinson, on June 11th. Anatomical diagnosis: Subacute puruent cerebrospinal leptomeningitis; hydrocephalus, puruent otitis media; bronchopneumonia, congestion of lungs; cloudy swelling of liver; swelling of mesenteric lymph

Body was much emaciated; 169 cm. in length; pupils equal, slightly dilated; discharge of purulent material from

each ear.

Brain: On removing the skull cap, the dura appeared injected and a little thickened, the convolutions flattened and the vessels of the pia injected. The tip of the left temporal lobe was swollen and had a cystic feel. All about the base of the brain was seen yellow pus, especially between the lobes of the cerebellum. The pia was everywhere thick-ened. The floor of the third ventricle behind the optic chiasm was purplish blue in color and bulged. On separating the cerebellum from the cerebral hemispheres a considerable quantity of clear watery fluid flowed out, in all about 150 c.c. The brain was put into formalin.

After hardening in formalin, a horizontal cut made through the lateral ventricles showed the latter considerably dilated, especially in the posterior and lateral horns. The choroid plexuses presented a curious appearance. At the point where each plexus curved downward into the descending horn of the ventricle, bands of inflammatory ties the ventricle of the ventricle. In addition, there was in the left plexus a firm, tumorlike mass, I cm. in diameter. The temporal a firm, tumorlike mass, I cm. in diameter. lobes were cut into from below; the wall here was very thin, measuring I to 2 cm. in thickness, and the descending horn of the ventricle was seen to be much dilated. choroid plexus, seen through the incision, presented the same appearance as that described from above. The left descending horn was somewhat more dilated than the right. At the tip of the left temporal lobe there was a small area of softening, I cm. in diameter, situated just beneath the gray matter.

Spinal Cord: Dura was somewhat thickened, tough, and

opaque. On opening it there was seen beneath the pia, at various places, small masses of rather dry, thick, yellow, purulent material almost caseous in consistence. The ves-sels of the pia were injected. The spinal cord was well preserved, and was quite firm in consistence. No enlarge-

ment of the central canal was seen.

On opening the middle ears, both were found to contain a considerable quantity of rather thick yellow, purulent material. There was no perforation of the tegmen tympani.

Grossly, there was found a cyst of the left temporal lobe. Both ventricles were dilated. There was a tumor in the left choroid plexus, and attention is drawn to the fact that on cutting through the peduncles in separating the cerebellum from the cerebral hemispheres there was an escape of 150 c.c. of fluid. The fact is explained by the infiltration of the Sylvian aqueduct by inflammatory tissue causing hydrocephalus.

Abscess of the temporal lobe occurs in ninety per cent. of the cases of chronic otitis media; it may be encapsulated or surrounded by softened brain tissue; it may be multiple or single. The abscess in this case came directly from the meningitis and the ear suppuration following.

Microscopical Examination: Sections through the wall of the lateral ventricles showed marked signs of inflammation; the subependymal tissue was infiltrated with round tion; the subependymal usua was infiltrated with round cells, densely so in the neighborhood of bloodvessels, and there was very evident proliferation of neuroglia tissue. In a few places the ependymal epithelium was absent. The choroid plexus was the seat of intense inflammation. Its vessels were greatly distended with blood, and the whole tissue was infiltrated with small round cells, chiefly of

Tumor: The tumor, which was described at autopsy, was

put into decalcifying fluid and showed the following: The tissue appeared to be identical with that of the choroid. Very large numbers of concentrically marked amyloid bodies were present, especially at the periphery. The centre of the tumor consisted principally of loose, reticulated tissue, not unlike lung tissue in appearance; the spaces in the reticulum were for the most part empty, though a few contained a translucent, homogeneous staining substance. contained a translucent, homogeneous stanning substance. A considerable area of the tumor was occupied by the remains of calcified substance. The blood vessels were greatly distended with blood, and the whole tumor was surrounded by densely packed round cells. Sections through the cortex cerebri of the temporal lobe, in the region of the abscess, showed the pia acutely inflamed, with its vessels congested, and its substance thickly penetrated with round cells. The brain substance where it formed the wall of the abscess was also densely infiltrated; and between the abseess and the surface of the gray matter, the blood vessels were everywhere surrounded by masses of round cells. Near the abscess, hæmorrhages into the brain tissue were

The cranial nerves were examined for degenerations by The cranal nerves were examined for degenerations by the Marchi and by the Weigert methods. The optic nerves showed a few degenerated fibres, seen by the Marchi method. The oculomotor nerves each showed a fair number of black stained fibres by this method. Degenerations were also present in both of the facial nerves. Examined by hæmatoxylin and cosin, the second, third, and seventh nerves were seen to be surrounded by inflammatory tissue, the inflammation involving the connective tissue trabeculæ within the nerves themselves. The condition was most

marked in the case of the seventh nerve.

It is very probable, judging from the condition of the chorioid plexus and from the fact that there were such marked bands of adhesions stretched from these across to the wall of the lateral ventricle at the beginning of the descending horn, that the flow of cerebrospinal fluid ac-cumulated and caused dilatation of the descending horns. The aqueduct lesion was in all probability caused by extension of the infectious process from the abscess in the temporal lobe. On its extension the process must have first affected the chorioid plexus; and these structures then underwent changes described, with possible dilatation of the descending horns of the lateral ventricles, and adhesions. Next, the third ventricle and the aqueduct of Sylvius were involved, and when the process of inflammation had succeeded in closing up completely the aqueduct, the hydrocephalus came to involve not only the descending horns but also the rest of the lateral ventricles and the third ventricle. That the process must have been chronic is shown by the presence in the exudate in the aqueduct, of young connective tissue

Spinal Cord, lumbar region: The pia is markedly infil-trated with round cells, and shows distended vessels filled with blood. In the white matter at the periphery of the cord there was seen some absorption of nerve fibres. Some scattered recent degenerations were present in the posterior columns in Marchi sections. All the tracts of the

white matter stained well by the Weigert method.

Cervical region of cord: The pia showed the same marked infiltration, and engorgement of its vessels with Marchi sections showed degenerated fibres in the posterior columns and in the crossed pyramidal tracts, as well as in the anterior roots. Sections stained normally by

the Weigert method.

Pons: Sections through the upper part of the pons showed the lumen of the fourth ventricle where this passes into the aqueduct of Sylvius, completely closed up by a mass of round cells. In a few places the normal lining epithelium of the wall was present, in one or two areas it epithelium of the wall was present, in one or two areas it appeared to be in process of proliferation. For the most part, however, the epithelium was absent, the round cells of the exudate fading into the surrounding tissues. These round cells were for the most part mononuclear in type; many had pale, vesicular, large nuclei. The blood vessels in the surrounding brain tissue were engorged with blood, and were surrounded by many round cells

In one of the corpora quadrigemina there was seen a small area of softening with some absorption of tissue; the walls of the cavity so formed consisted of necrotic tissue.

Following the case of Dr. Hutchinson I have had a case to examine from the service of Dr. Lloyd, at the Philadelphia Hospital, which has been similar in showing a blockage of the aqueduct of Sylvius.

CASE II .-- A man, colored, aged thirty years, came in a stuporous condition; he showed symptoms of meningitis. He died in a few days, and the brain showed meningitis and some hydrocephalus. This hydrocephalus was caused by blocking up of the aqueduct of Sylvius with a round celled infiltration extending in as far as the middle of the

superior colliculus

Sections showed portions distended with round cells and at some points the canal had broken open and the nervous tissue infiltrated with inflammatory material. This blockage had caused a moderate distention of the ventricles. There was some infiltration of the walls of the ventricles, but of a slight grade. The chief focus in the ventricles seemed to be at the entrance to the aqueduct and extending into it. There was a marked tuberculous meningitis, especially at the base of the brain. This process was apparently secondary to tuberculosis of the other parts of the body, for the autopsy disclosed tuberculosis of the lungs, liver, spleen, kidneys, and peritonæum.

There was no change in the ependyma or chorioid, of the third and lateral ventricles, but there were inflammatory

changes in the floor of the fourth ventricle.

It would seem that the source of infection was via the foramen of Magendie, and hence into the aqueduct.

THE DIAGNOSIS OF ACUTE MILIARY TUBER-CULOSIS*

BY SILVIO VON RUCK, M. D., Asheville, N. C.,

Associate Medical Director, Winvah Sanatorium, Asheville, N. C.

Acute miliary tuberculosis is a disease so varied in its clinical manifestations, even independently of the distribution of tubercle in the different organs, and in individual cases so closely simulates other affections, that its diagnosis is often attended by no little difficulty.

Especially is this true if the case has not been observed from the beginning and when a reliable

history is not available.

When the question of distinction arises the history is often of great aid and a careful physical examination may assist materially in the individual case, if the presence of an old tuberculous focus be thereby revealed. In tuberculous or so called scrofulous persons, and in those who give a history of previous tuberculous affections of internal organs, we should not fail to enquire regarding the possible relation of traumatic influences. Again the appearance of suspicious symptoms in the course of several weeks after surgical operations upon tuberculous bones and joints, lymph glands, and other parts, is suggestive of generalization of the tuberculous infection. In instances with a meningeal onset in young children, the coexistence of a chronic otitis or mastoid disease may throw light on the cause of the symptoms.

In every case it should be borne in mind that we are dealing with a secondary process which has its origin from a primary focus somewhere in the body.

Although such ætiological enquiries are important and may assist greatly in making a correct diagnosis, especially in instances in which tuberculosis is found, it is nevertheless essential to avoid hasty conclusions, and this is particularly true when the

^{*}Read by title before the Medical Society of the St te of North Citolina, at Winston, June 16 to 18, 1908.

symptoms are atypical. For example, in young children, though they have a tuberculous family history or perhaps glandular tuberculosis, we may actually be contronted with a bronchopneumonia that has given rise to convulsions, and to the undue rapidity of the respiration and the pulse, which may reach a degree in generalized bronchitis that equals or exceeds the frequency commonly observed in acute miliary tuberculosis.

Thus the history of, or presence, of tuberculosis is but a link, although an important one, in the chain of circumstantial evidence upon which we may base our final opinion, and this is true of all symptoms, every one of which may have another explanation when considered independently of the rest.

The respiratory insufficiency is one of the most constant, and in the absence of physical signs which could explain it, it is one of the characteristic symptoms of the pulmonary form of the disease. When this has been preceded with the usual onset of general malaise, loss of appetite, and the patient has at first slight and then increasing dry cough, when we can exclude a local lung affection or a pleural effusion, when there is no evidence of a pericarditis or endocarditis, and the pulse is weak and unduly increased in frequency, with or without the irregular fever, the evidence becomes strong in favor of miliary tuberculosis of the lung, and more so still if we have at the same time support from an ætiological point of view.

In such cases one will rarely err in the diagnosis of miliary tuberculosis of the lungs if the symptoms increase in intensity and there is also rapid loss of weight. The latter is a prominent feature in almost every case of acute miliary tuberculosis, and may be seen in instances in which the fever is of a mild type and when a fair amount of nourishment is taken by the patient. The diagnosis would still be supportable in instances in which signs indicative of consolidation appear in the lung in the course of the disease, and the sputum becomes streaked with blood or actually becomes rusty for a time; nor would intercurrent pleural pain or signs of an effusion require its reconsideration. The later advent of more marked dyspnæa with cyanosis still further strengthens the evidence, and the diagnosis is eventually established, even though none of the symptoms are pathognomonic and ætiological support is lacking.

The physical examination of the chest shows, as a rule, nothing characteristic, but can still aid us in certain cases. The examiner may be confused in instances in which the affection develops in the course of whooping cough or phthisis, when cartarrhal affections belonging to the preexisting pulmoutary disease are present, the more so if he has not himself been familiar with the local auscultatory phenomena, prior to the advent of symptoms indicative of a generalization. In such cases the results of the physical examination of the chest are not available for diagnostic consideration, excepting as a basis for estimating in how far they may be accountable for the property and dyspacea, and the general condition of the patients.

On the other hand records of, or reliable information of the recent chest examinations are often of have shown the disease limited to certain areas, while other portions of the lungs were free from catarrhal signs. When in such cases no change is apparent or the catarrh appears to have become generalized, and especially when this is indicated by a sense of stickiness, crepitant and subcrepitant râles, suggestive of bronchiolitis, the result of the chest examination may give important support to the diagnosis.

Early pleural symptoms, especially pain, are often mentioned in the description of cases. Jürgensen (1) described a peculiar rubbing or a soft friction sound without local pain, which he noted in acute miliary tuberculosis, both on auscultation and by palpation; this he attributed to the presence of miliary tubercle in the pleura and which he and Litten confirmed by finding corresponding tubercle at autopsy. Similar observations have since been made by Burkart (2), Hager (3), Riesman (4), and others, who have noted this peculiar rubbing in exceptional cases.

In the pulmonary form the early negative findings, or the development of a diffused catarrh, the dyspnœa, and increased pulse rate are the chief features and may continue to be so until the end, unless meningitis develops in the further course, The fever attracts often but little attention, although it is rarely entirely absent. Careful observations should always be made, and the temperature should be measured in the rectum, the dyspnæa and mouth breathing preventing the usual approximation to correctness of the mouth temperature. Frequently we find that the fever which before was absent or intermittent has assumed an irregular remittent type, and that the normal is not reached at any time during the twenty-four hours, and occasionally an inverted type of the fever curve may occur. latter is, however, also observed in other diseases, and is perhaps as frequent in acute pneumonic phthisis as it is in acute miliary tuberculosis. When the earlier course leaves us in doubt, the subsequently increased signs of pulmonary obstruction and of prostration, and the occurrence of delirium, the pallor, the continued emaciation, and, as already stated, the absence of physical signs to account for the dyspnœa aid in excluding other causes.

In distinctive diagnosis of the pulmonary form from other affections of the lungs we have to consider more particularly pneumonia and bronchitis.

Bronchopneumonia and acute capillary bronchitis, especially in young children, can cause great resemblance. Even the prodromal stage may correspond in cough, slight fever, loss of appetite, or the onset may be sudden in both affections with convulsions. Henoch (5) reported several cases of pneumonia of the upper lobes of children in which the symptoms were suggestive of meningitis.

The respiration and the pulse can have an equal frequency, and the fever may be equally high. The demonstration of consolidation in the lung, and especially the presence of bronchial respiration, would be suggestive of pneumonia. If the case has been seen from the beginning we have been able to observe the dry stage of the catarrh to be followed by moist râles, and have been able to note its progressive extension from larger to smaller bronchi; this would likewise speak in favor of pneumonia. A

diffuse capillary bronchitis, however, is in itself characteristic of miliary tuberculosis of the lungs, and unless we have the aid of other symptoms, especially on the part of the nervous system, the diagnosis may remain in doubt, or be shown in error at autopsy, in cases that are rapidly fatal. Such difficulties are not frequently encountered; the onset of miliary tuberculosis is, as a rule, slower, and the physician is liable to see the case before the pulmonary symptoms are developed to a degree that exudative inflammations in connection with dense deposits of miliary tubercle can resemble a pneumonic consolidation of the upper lobes. Moreover, such a complication in acute miliary tuberculosis is in itself very rare. The bronchiolitis caused by miliary tubercle in the lung is, as a rule, preceded by increased frequency of the respiration and by dyspnœa, and in the earlier period the chest examination is either negative or the inspiratory murmur in the upper lobes is markedly feeble as compared with that of the lower, and when catarrhal signs appear they develop in a reversed order, originating and extending from the smaller to the larger bronchi. We are therefore liable to hear first but few and later more crepitant or subcrepitant râles, in portions of the lung that are resonant, or hyperresonant on percussion. In contrast with ordinary bronchiolitis at this time the lower posterior portions are often less involved than the upper, and there is no evidence of downward extension of the catarrhal process, unless by mere coincidence which may have been in a case observed by West (6) of a boy, nine months old, who was seen two weeks after contracting a cold, and in which he diagnosticated catarrhal bronchitis. The child died six days later of dyspnæa, and the autopsy showed miliary tuberculosis of the lungs.

In adults acute croupous pneumonia is not liable to be mistaken for acute miliary tuberculosis of the lung, although when in the course of the latter typical rusty sputa appear one would naturally think of the former. In such rare cases exudative pneumonic foci are probably associated, but when situated in the upper lobes they are suggestive of tuated in the upper lobes they are suggestive of tuated in the upper lobes they are suggestive of tuated in the upper lobes they are suggestive of tuated in the upper lobes are suggestive of the abrupt onset of croupous pneumonia often with a chill, the regular fever, and the marked physical signs in the lower lobes, as well as the general course, and the appearance of the patient difference of the prevent error.

Pneumonia and bronchitis in adults are more liable to lead to diagnostic difficulty when occurring in aged persons and especially in those who are otherwise decrepit. Very often such affections begin insidiously, and there is a gradual development of dyspnæa, cyanosis, and irregular fever, with local signs of a diffused bronchitis; the illness is attended with much prostration and general exhaustion, and leads to death more or less rapidly. In such cases a generalized miliary tuberculosis which has followed a chronic or subacute type may be found unexpectedly at the autopsy.

A pleurisy with effusion could be thought of in cases in which the miliary process of the pleura causes marked exudate, and when the patient is first seen in this stage. It could, however, be in rare instances only that a careful enquiry and examination of a patient who suffers from acute miliary tuber-

culosis would not exclude ordinary pleurisy as the cause of all that can be found and observed in such cases.

Embolism of the pulmonary artery, when of small size and involving numerous branches successively, or when in a larger branch the obstruction develops gradually, may give rise to symptoms which can correspond more or less with those caused by miliary tuberculosis of the lungs, and death may occur in the course of several days or weeks, with signs of respiratory and circulatory insufficiency. Nevertheless, the clinical picture differs, and even when such changes occur gradually, the patient has experienced a more abrupt change in respiration. At the same time, his attention has been attracted to the disturbed heart action which occurs simultaneously and which continues forcibly, often with precordial distress, while the small, irregular pulse in connection points to obstruction in the pulmonary circulation as the cause of the dyspnæa and cyanosis. If the embolism is not of septic origin there is no fever, and although the patient does not think of the relation, the physician would necessarily enquire and look for phlebitis, or appreciate the probable relation of a septic affection, or of crushing injury to bone, etc., in the course of which the accident has occurred.

In the typhoidal form, the difficulties in diagnosis, in so far as we seek to establish it upon symptoms, are liable to be greater than they are in cases in which pulmonary or meningeal symptoms are prominent. In many cases the coexisting symptoms of respiratory and circulatory insufficiency are important aids in distinguishing it from typhoid fever, and the temperature curve and rapid emaciation are likewise liable to direct the attention to the true nature of the disease.

However, the resemblance in some cases which have been reported has been most complete. Senator, among others, has recorded such cases in 1881. . in one of which the autopsy showed acute miliary tuberculosis, although the type of fever, the presence of splenic enlargement, roseola, distended abdomen, dicrotic pulse, difficult hearing, epistaxis. singultus, and eventually the occurrence of purulent parotitis, all appeared to speak for typhoid fever. But such cases are exceptional, and ordinarily the two diseases present striking differences, which cannot escape the observation of the attending physician, and even in the more irregular types a careful study of the fever, pulse, and respiration will, in most instances, enable him to arrive at a correct decision.

In acute tuberculosis the fever may be continuous with scarcely any morning remissions. It is then more continuous than typhoid, and the typical typhoid curve is missing. In other cases it is intermittent, the remissions are irregular, or it may be of an inversed type, as has already been mentioned.

The pulse, as a rule, exceeds in frequency that which would be in harmony with the existing fever, a fact which has been pointed out by all observers. In the fully developed disease 120 to 130 pulsations to the minute are not uncommon, and with increasing pulmonary obstruction the rate may be increased to 150 or more, even when the fever is comparatively low.

Increased frequency of respiration is noted at

times quite early, but it usually belongs to that period in which tubercles have formed in the lungs. As the disease progresses the frequency naturally increases, the respirations become gradually deeper, and a true inspiratory dyspnœa results. Even in adults 40 to 60 respirations a minute are not unusual, and in children this may be much exceeded.

The marked enlargement of the spleen as it occurs in typhoid is rare in acute miliary tuberculosis, and a palpable spleen speaks strongly in favor of the presence of the former, especially in adults. A. Fränkel (7), however, found that in children the splenic enlargement may become equally marked. Wagner (8) and also Fränkel (9) have called attention to the enlargement and pain on pressure of the liver in children, when this organ is included in the miliary dissemination. Fränkel has seen severe icterus, and in either children or adults he believes an enlarged liver speaks for tuberculosis rather than for typhoid.

When the correspondence of symptoms is complete the question of distinctive diagnosis does not arise, but in general practice where laboratory facilities are not available, such cases still continue to afford occasional surprises upon the autopsy table. When, however, such facilities are at hand, we now have additional aids in bacteriological examinations and serum reactions. Regarding the latter a characteristic positive Widal reaction on the one side or a marked Arloing-Courmont reaction on the other, is rarely misleading, but it must be remembered that tuberculous subjects often show a modified Vidal reaction which, though less marked than in typhoid fever, may cause confusion, and that the Arloing-Courmont test may prove entirely negative in tuber-

culosis.

In all doubtful cases in which the question of typhoid fever enters into the distinctive diagnosis, bacteriological examinations of the blood, urine, and faces for the demonstration of Eberth's bacillus should be made.

In cases in which acute miliary tuberculosis occurs with or soon after convalescense from typhoid fever, it may be mistaken as a relapse, especially so when the course of the primary disease has been typical and the diagnosis was well established. In such cases great difficulty may be encountered when the symptoms are atypical, and the bacteriological examinations just referred to avail nothing in the recognition of the complication.

Unless the examination of the blood should again show Eberth's bacillus or clear up the doubt by the presence of tubercle bacilli, we must depend upon the analysis of symptoms, and the demonstration of choroid tubercle when meningeal symptoms are present, which suggest a basilar localization.

The diagnosis of the meningeal form of acute miliary tuberculosis offers less difficulty when meningeal irritation and inflammation occur, after characteristic pulmonary, with or without typhoidal symptoms, have been observed in its earlier course. In such instances the occurrence of meningitis, although obscuring for the time the pulmonary affection, removes, as a rule, any previous doubt, and confirms the tuberculous origin of the preceding symptoms as well as of the meningitis.

Cases with meningeal symptoms have been observed in which the on ct and course were not sufficiently distinctive to exclude tuberculous meningitis, and in which the distinctive diagnosis, especially from typhoid with complicating meningitis due to Eberth's bacillus or from pneumonia with associated pneumococcus meningitis has at first proved more or less perplexing. Our chief dependences for exact information, then, are the specific sera reactions, the examination of the fundus of the eye, examination of the spinal fluid, obtained by lumbar puncture, and the bacteriological examinations of the blood and secretions.

In the ophthalmoscopical examination of the fundus, choroidal tubercles have been found with various frequency, but, as a rule, at such a late period that the nature of the affection was established on clinical grounds long before. In rarer instances the discovery of choroidal tubercle has become an aid in diagnosis. B. Fränkel (10) reported such a case in 1869, in a child, age six, in which he found choroidal tubercle although meningitis was absent, nor did it appear in the subsequent course.

In a second case he found them ten days prior to the onset of meningeal symptoms. Brüire (11) was able to make a distinctive diagnosis from typhoid fever, and Loeb (12) succeeded in the same.

way by finding tubercle of the choroid.

While the ophthalmoscopical examination is but rarely of aid, in the early period of the disease and never in the initial stage, the presence of tubercle of the choroid supplies absolute evidence that more or less generalization of a tuberculous process has occurred, and, like the demonstration of tubercle bacilli in the blood or the appearance of miliary tubercle upon visible mucous membranes in the course of the disease, it removes all previous doubt, in instances where the general symptoms justify the diagnosis upon clinical grounds only.

In cases in which meningeal symptoms occur early and predominate in the prodromal and subsequent periods, the slower onset and more protracted course speak for a tuberculous origin. Such cases differ then but little from tuberculous meningitis, without generalization, the consideration of which does not fall within the scope of this paper.

In cases of acute miliary tuberculosis, tubercle bacilli have been occasionally found in the blood.

Weichselbaum (13) was the first to find them in the heart clot of three cases which he examined, and at the same time he succeeded in demonstrating their regular presence in the miliary tubercle. Meissels (14) confirmed Weichselbaum's autopsy findings, and he further found tubercle bacilli in one of two cases examined during life. Lustig (15) also found tubercle bacilli intra vitam in one case and in the heart clot after death in eight others.

Reutimeyer (16) demonstrated tubercle bacilli in the fluid withdrawn with a hypodermic syringe from the spleen, sixteen hours before death, and Sticker (17), Doutrelepont (18), and Ulcacis (19) found typical bacilli in blood specimens taken from the finger tip. The last named authors were able to demonstrate them at a time when the diagnosis between typhoid fever and acute miliary tuberculosis was in doubt. Tubercle bacilli have since been found in the blood by various others by direct examination of stained specimens taken during life, but this method frequently fails, and the animal experiment is necessary for their demonstration.

Most authors have failed to find tubercle bacilli in the blood sufficiently early to render their demonstration of value in distinctive diagnosis. Nevertheless, Wild (20) and Ribbert (21) think that tubercle bacilli are present in the blood more constantly than former examinations have indicated, and they even believe in their multiplication in the blood. The more recent observations of Jouset would, in

some respects, confirm these views.

Jousset (22) by his method' found tubercle bacilli in the blood in almost half of the cases of acute and subacute phthisis which he examined. He succeeded in demonstrating them with especial frequency in caseous pneumonia, and in two cases he was able to make the distinctive diagnosis of acute miliary tuberculosis from typhoid fever. The frequency of his observations has, however, not been confirmed by other authors, among them Bonardi (23) who, nevertheless, considers the method of great, and even of as much value as the serum reactions of Arloing and Courmont, and the tuberculin test in certain cases. Debove (24) also thinks favorably of the method.

In the urine of a case of acute miliary tuberculosis in which the diagnosis pointed to typhoid fever, Pröbsting (25) found tubercle bacilli, and in the further course choroidal tubercle was also demonstrated. The autopsy in this case showed caseous changes in the kidney indicative of an older lesion. Kleczetow (26) diagnosticated acute miliary tuberculosis in two cases by finding tubercle bacilli in the urine, and recommends its examination in doubtful cases.

Baumgarten (27) and others have obtained positive results from inoculations with urine, but for diagnostic purposes experimental tests with blood and urine are too slow.

What aid may be derived from the conjunctival administration of tuberculin as suggested by Calmette and from cutaneous administration known as won Pirquet's method remains to be seen. Bandler and Kreibish (28) failed in obtaining a reaction by the cutaneous method in four cases of miliary tuberculosis of mucous membranes; all these patients had high fever and were otherwise cachectic, which is in accordance with Pirquet's own observations that miliary and cachectic cases do not react.

Eyre, Wedd, and Hertz (29) obtained a positive conjunctival reaction in a case of tuberculous meningitis, and failed in another in which the comatose stage had been reached thirty hours before death. On the other hand, Cohn (30) found that a reaction was frequently obtained in typhoid fever patients, especially in the stage of convalescence. Further observations are necessary to establish the reliability of either method, but as they are unattended with danger and applicable in the presence of fever.

there can be no objection to their trial in cases where the subcutaneous administration of tuberculin is contraindicated.

The urine shows nothing characteristic. It is, as a rule, diminished in quantity, sometimes very scant, and Rosenstein (31) has noted anuria in children, probably depending upon implication of the kidneys in the miliary dissemination. Slighter degrees of albuminuria are often present, and Munro (32) noted albuminuria in eleven of seventeen cases which were confirmed by autopsy. Acute renal tuberculosis existed in over seventy per cent. of these cases. In six cases without albuminuria the kidneys were thus affected in but three instances.

The presence of indican, especially in children, to which Hochsinger called attention as of aid in distinctive diagnosis, and which Djouritsch (33) also thinks valuable in this respect, occurs in other gastrointestinal affections. Monti (34) found it only in very severe cases, and never in the beginning, and other authors who investigated the subject in acute and chronic tuberculous affections of children. as, for instance, Noute (35) and Steffen (36), attach no diagnostic import to its presence.

The diazo reaction while not available for distinguishing typhoid fever may be of aid in the diagnosis of the pulmonary and the meningeal form. Nissen (37) found the diazo reaction in ten of fifteen children, suffering from acute miliary tuberculosis, it having preceded the onset of meningeal symptoms for a period of from four to eight days in eight of his cases.

Kephallinos (38) recorded the diazo reaction in twenty-two of forty-six children with generalized miliary tuberculosis and coexisting meningitis.

In certain cases in which acute miliary tuberculosis follows its course without distinctive symptoms, presenting the clinical picture of some other disease, a positive diazo reaction will be of diagnostic value; for example, in such cases as reported by Strauss (39), Reinhold (40), and others, in which before death there were only symptoms of acute polyarthritic rheumatism, although the autopsy showed general acute miliary tuberculosis. Rheinhold's case of a young woman, aged eighteen, progressed under the symptoms of erythema nodosum with rheumatoid manifestations, until symptoms of meningitis developed unexpectedly.

Other unusual clinical symptoms suggestive of septic processes by the occurrence of well marked chills at irregular periods with great variation in temperature, or periods of intermission will at times draw the physician's attention in an entirely different direction, as shown by the cases reported by Fischel (41) and by Späth (42) in which acute miliary tuberculosis developed during the puerperium. Späth's case appears to have been complicated by a puerpural infection, but in the case of Fischel, there was no such evidence, and it is of interest additionally, by an intermission of symptoms sufficient to warrant the patient's discharge from the

In the foregoing consideration of the diagnosis of acute miliary tuberculosis there will be found nothing new or original, but I have endeavored in the light of present knowledge to review the subject as practically as possible in the time allotted, and expected.

^{&#}x27;Jousset's method, which is also applicable to pleural and peritoneal students, is for blood, as follows. From to to be set of blood are taken from a vein by means of a sterilized syringe and diluted with 150 to 200 c.c. of sterilized water. After coagulation has occurred the clot is filtered out upon a boiled compress and washed with sterile distilled water to remove all serous fluid. It is then placed in a flask, to which are adoled to be accompanied to the sterilized water. The fluid of the sterilized water, and the sterilized water, and the sterilized water, and the sediment of social methods and 1,000 grammes distilled water). The fluids is placed in the incurrent of social methods and 1,000 grammes distilled water). The fluids with the sediment of social methods hours, digestion being bastened by agitating every half hour. The resulting fluid is centrifugalized and the sediment stained for the bacilli. To fluids which do not coagulate spontaneously or in the examination of urine he adds a small amount of blood plasma from the horse.

pecially to emphasize the more important points which are of real value in the distinctive diagnosis from other affections.

Briefly these may be summarized as follows:

I. The rapid emaciation which is a striking feature in almost every case, and which is out of all proportion to the degree of fever, the state of the digestive organs, and the amount of food taken.

2. The bronchiolitis of acute miliary tuberculosis of the lung is characteristic in that the catarrhal signs appear first in the smaller and then extend to the larger bronchi, instead of in the reverse order as in ordinary bronchitis. In further contrast to ordinary bronchiolitis the lower posterior portions of the lung in acute miliary tuberculosis are often less involved than the upper.

3. Cases in which typhoid fever is minutely simulated by acute miliary tuberculosis or in which the two diseases coexist are rare, and a careful study of the pulse, temperature, and respiration will usual-

ly lead to a correct distinction.

4. Serum reactions are reliable when present in well marked degree, but tuberculous patients may show a modified Widal reaction and the Arloing-Courmont reaction is not always present in tuber-

5. The ophthalmic test as applied by Calmette and the cutaneous application of tuberculin according to the method of von Pirquet, while not yet established as thoroughly reliable, are safe, and one or both should be employed in all doubtful cases, especially if the subcutaneous injection of tuberculin is contraindicated.

6. Bacteriological examinations of the blood, fæces, and secretions may be of great aid in doubt-

ful cases.

7. The appearance of choroid tubercle or miliary tubercle of visible mucous membranes in the course of the disease removes all doubt.

THE OPSONIC THEORY AND ITS PRACTICAL APPLICATION.*

By A. CLIFFORD MERCER, M. D., Syracuse, N. Y.

Professor of Rediatues, Syracuse University, Physician, Syracuse Hospital for Women and Childeen, Consulting Physician, Syracuse Free Dispensary,

An opsonin' is an internal secretion found in the blood fluids, plasma, and serum. Just where opsonic metabolism in body cells takes place is unknown. Fluid extracts of glandular and connective tissues have not been examined for the purpose of estimating their comparative opsonic content and thus discovering, possibly, the seat of opsonic production.

"Read before the Syracuse Academy of Medicine April 16, 1907, and now (November, 1908) revised for the New York Medical

And how (November, 1908) revised for the latin from the Greek means a caterer or one who prepares food for another. An opsonin is supposed to combine chemically with a bacterium and, thereby, to convert this otherwise unattractive vegetable into palatable food for a lemostre. The term opsonin was first used by Wright and

An opsonin belongs to a class of immunizing antibodies of which agglutinins and antitoxines are members, but the relation of opsonins to other antibodies has not been satisfactorily determined. An opsonin in its own peculiar way is a defender of the body against the attacks of some particular

microorganism.

It is probable that opsonins are produced by cells which have become more or less specialized through long stages of animal development to help higher organisms to resist bacterial invasion. Thus the opsonic function in man would be developed with use in overcoming the microorganisms which constantly enter the body, usually in small numbers, but from time to time in almost overwhelming hosts. Each microorganism susceptible to opsonic resistance would thus develop its own opsonin. In harmony with such a probability it is found in vitro that when a normal serum loses its staphylococcopsonin, for instance, there still remains in the fluid, for example, the normal amount of tuberculo-

opsonin.

Be the origin of opsonins what it may, a healthy man has what may be regarded as a normal amount of each of various opsonins as a constituent of his blood plasma and the lymph permeating his tissues. With normal amounts of opsonins in plasma and lymph, and a normal condition of opsonogenetic cells, the healthy man has a normal resistance to bacterial invasion. Persons havng a less or greater than normal amount of an opsonin in their tested serum have a respectively less or greater resistance to the corresponding bacterial disease. When an average normal amount of an opsonin found in tested serum is represented by the figure I, less amounts by figures less than I, and greater amounts by figures greater than I, such figures become opsonic indices of patients' resisting power to a bacterial infection. The tuberculoopsonic index of a somewhat large number of tuberculous and nontuberculous subjects has been determined. Such determinations show that the tuberculoopsonic index in the nontuberculous has a range of from 0.8 to 1.2, while in patients suffering with localized and afebrile tuberculosis the tuberculoopsonic index is usually below o.8. These patients have a low tuberculoopsonic index corresponding with their low resistance to tuberculous infection.

In cases of furunculosis, acne, or sycosis due to a staphylococcic invasion the staphyloccoopsonic index is found to be low, perhaps 0.4, as compared with the average normal staphylococcoopsonic index. In pneumococcic empyema the pneumococcoopsonic index is low. In gonorrheal arthritis the gonococcoopsonic index is low. In cystitis due to an invasion of bacilli coli communis the corresponding bacillary opsonic index is low. These are examples of infections which, if not treated, are likely to be indefinitely prolonged, because they do not improve so long as their opsonic index remains In self limited infections with a definite ending the early low opsonic index gives place toward the close of the disease to a normal or high opsonic index. For instance, in the early stages of lobar pneumonia the pneumococcoopsonic index is low, while at the crisis it is normal or high. a case of unresolved lobar pneumonia the pneumococcoopsonic index continues to be low until the opsonogenetic cells secrete more opsonin and finally enough to overcome the remaining pneumococcal activity. If, on the other hand, the opsonic function fails to respond properly to the needs of the patient, disaster results.

In a self limited bacterial infection the microorganism which enters the body and causes the symptom complex of the disease at the same time stimulates the opsonic function to increased activity, as may be recognized by a low opsonic index gradually becoming higher; and thus the latent powers of bacterial defense are aroused, the more abundantly produced opsonin attacks the microorganism and so changes it in some way that the polymorphoneuclear leucocytes, previously passive, now promptly engulf and destroy it by phagocytosis. In the indefinitely prolonged bacterial infections the opsonic index remains low for long periods because the localized invasion is more or less walled off from freely moving blood and lymph currents, and is, therefore, imperfectly flushed out by the fluids which would otherwise carry bacteria from the interior of the lesion out into channels through which they would reach and stimulate opsonogenetic cells. In these cases which lack the internal opsonogenetic stimulus from their own localized lesions it is practicable to introduce by hypodermic methods a suitable stimulus from outside the body into the patient's subcutaneous tis-This stimulus consists of an estimated number of dead microorganisms of the same species, or, better still, of the same strain, as those responsible for the patient's infection. Pure cultures grown from microorganisms obtained from the patient's own lesions are best. These are killed by the least amount of heat which is known to be surely effectual, an amount which varies somewhat with the different microorganisms met with in localized lesions. The number of dead microorganisms is estimated for the purpose of regulating the size of the dose. Ready for inoculation the dead microorganisms are known as vaccine. In many instances when this suitable stimulus, consisting of the right amount of vaccine inoculated with proper intervals between the doses, is given to a patient who suffers with a local infection, which may have baffled all treatment for months or years, he immediately improves and is soon well.

The adjustment to the needs of the patient of the size of the dose and of the length of the intervals between the inoculations is governed by a record of the patient's opsonic index to the microorganism responsible for the infection. After proper inoculation in the case of a localized staphylococcic invasion, for instance, the patient's already low staphylococcoopsonic index will at first become still lower. Temporarily the opsonic function seems to be paralyzed, the production of opsonin apparently stops, while some of the opsonin, already a constituent of plasma and lymph, is probably used up in the bacteriophagocytic battle going on in the walls of the localized lesion. In harmony with this probability is the observation that when the same inoculation is given to a man in health the opsonic index falls little, if at all, which may be due to the battle going on in his body to draw upon the opsonic content of his plasma and lymph. After the early drop in the staphylococcoopsonic index of the properly inoculated patient the index gradually goes up to a point well above the average normal staphylococcoopsonic index. This rise in the opsonic index corresponds with the response of the opsonic function to the vaccine stimulus. From the high point the opsonic index falls again to a point below normal, but not to a level quite so low as that recorded before the patient was inoculated. somewhat higher, although still low, opsonic index is maintained for a while. If the inoculation is repeated at the best time, soon after the opsonic index begins to drop from its highest point, the result is similar to that which follows the first inoculation; but after a properly timed second inoculation the maintained higher level of the opsonic index is somewhat higher than it is after a single inoculation. Thus, by repeated inoculations of the right amounts of vaccine at proper times, the opsonic index can be raised considerably, and, pari passu, in the case instanced, the patient's resistance to staphylococci can be increased to such an extent as to enable him to overcome and get rid of the localized infection. If the initial dose of vaccine has been too large, the paralytic stage is lengthened so that the opsonic response is delayed or fails altogether. If a dose is repeated during the paralytic stage, this stage is emphasized, and again the opsonic response is delayed and may fail altogether. The excessively lowered opsonic index of the emphasized paralytic stage means a very low resistance to bacterial infection and hence probable disaster to the patient. As there are no clinical symptoms definitely characteristic of the paralytic stage, or of the period of opsonic response, the opsonic index becomes the only guide the physician has to enable him to adjust the size of the dose and the length of the intervals between the inoculations to the varying needs of different patients.

With the opsonic index as a guide quite a large number of localized infections have been investigated and successfully treated. A classified list of

these follows:

A: Those due to Staphylococcus pyogenes; I,

furunculosis, 2, pustular acne, 3, sycosis.

B: Those due to pneumococcus of Fraenkel; I, empyema, 2, cystitis, 3, suppuration of antrum, 4. corneal ulceration.

C: Those due to Bacillus coli communis; I, cystitis, 2, various local affections.

D: Those due to the gonococcus; 1, gleet, 2, gonorrhœal arthritis, 3, acute gonorrhœa.

E: Those due to Bacillus tuberculosis when the

lesions are strictly localized; I, lupus and tuberculous ulceration of the skin and subcutaneous tissues. 2. tuberculous diseases of bones and joints, 3, tuberculous cystitis, nephritis, epididymitis, peritonitis, adenitis, laryngitis, iritis, phlectenular con-

Thus far we have considered only well localized infections, in which the opsonic methods exhibit their more brilliant results. Successes, however, are recorded in the treatment of less localized or more systemic infections due to the bacillus tuberculosis, and at least one bidhaut result has been

obtained in a case believed to be septicæmic endocarditis due to a staphylococcic infection.

In cases of strictly localized tuberculous infections the tuberculoopsonic index is, as a rule, steadily low, and thus resembles the steadily low opsonic index common to other localized infections. In less strictly localized or more systemic tuberculous infections, as in pulmonary tuberculosis, for instance, the opsonic index is not steadily low. fluctuates widely from points below the normal tuberculoopsonic range to points above that range and vice versa. The fluctuations are irregular in extent and in the time of occurrence, and they are thought to be due to autoinoculations which are poorly adjusted to the needs of the patient both as to the size of the doses and the intervals between them. Autoinoculations occur when for any reason the flow of plasma and lymph to and through the affected tissues is increased to an extent to favor the washing out of bacilli from an imperfectly walled off or wallless lesion. Physical and mental efforts will increase the flow. For instance, attendance and dancing at a ball caused an autoinoculation which lowered the tuberculoopsonic index several tenths.

The plan of opsonic treatment in a more systemic tuberculous infection is, if possible, to convert the invasion into a localized infection. When this can be accomplished the case may be successfully treated as localized infections are treated. It is a general truth that the more resistence a patient has the more is his infection likely to be or to become localized. Therefore, in the case of a less localized tuberculous infection every effort is made to increase the resisting power of the host. The febrile patient with a widely fluctuating tuberculoopsonic index is given absolute rest outdoors under a sanatorium type of management and, if possible, at a sanatorium. Thereby his circulation becomes more slow and steady locally as well as generally. At the same time his metabolism improves in his opsonogenetic cells as well as elsewhere. He is given large quantities of milk which by means of its lime content increases the coagulability and viscosity of his blood, thus retarding circulation in tissues that may, under the favorable conditions now brought about, take on wall forming activity and convert the lesion into a more strictly localized infection.

Having accomplished this conversion, the tuberculoopsonic index becoming steady, there may come a time when the infection will be so strictly localized as to share with other localized bacterial lesions the benefit that may be derived from certain contributory measures which are sometimes used together with opsonic inoculations. The patient is to be safeguarded during the use of these measures, as he is safeguarded while receiving opsonic inoculations, by an opsonic index record. The measures consist of such general or local exercise as will excite a proper increase of circulation of plasma and lymph into and through the affected part, which, on the one hand, takes opsonin deeper into the walls of the lesion there to aid phagocytosis and, on the other hand, tends to wash out from the lesion small amounts of the microorganism to serve as the vaccine of autoinoculation. Bier's hyperæmia treatment is sometimes used to bring about similar results.

The irritant effects of Finsen light or x rays, for example, are in themselves frequently so successful in cases of lupus as to make opsonic treatment unnecessary; but when Finsen light or the x ray no longer benefits a case of lupus the addition of opsonic inoculations may complete a cure. In the light of opsonic methods the application of irritating iodine to the skin over tuberculous lymphatic glands becomes a rational procedure. In suitable cases, to decrease the coagulability and viscosity of the blood and still further to favor the free movement of plasma and lymph through the tissues of the affected part sodium citrate is added to the milk, to precipitate the lime content of this still desirable food, and citric acid is prescribed, to combine with and precipitate from various other ingesta such soluble lime salts as might otherwise become blood constituents.

The auxiliary measures used in cases of more strictly localized tuberculosis are also indicated in other localized infections. When a subcutaneous staphylococcic abcess has evacuated its pus, either spontaneously or after incision, no staphylococcoopsonin is found in the pus. But the lymph which afterwards pours into the abcess cavity contains, as a rule, staphylococcoopsonin. The lymph now contains more than enough opsonin to satisfy the phagocytic demands of the abcess wall through which it passes, and the surplus can be detected in the discharge from the cavity. But if the supply of opsonin is for some reason deficient and the healing process lags, a fuller flow of opsonin carrying lymph to the part may be brought about by poulticing or by washing out the cavity with slightly irritating bactericidal fluids. It is possible that laparotomy in tuberculous peritonitis is curative in a similar way. Exposure to entering air may result in enough peritoneal irritation to determine a curative flow of opsonin carrying lymph into the locally infected tissues.

Not only is the opsonic index a guide to correct methods in the treatment of infectious diseases by inoculations, but it is also a guide to the surgeon who wishes to remove by operation some local infection, as, for instance, a tuberculous gland or tuberculous granulomata in a joint. The surgeon avoids the paralytic stage, or "negative phase," of autoinoculations and chooses a time for operation in the stage of opsonic response, or the "positive phase," of an autoinoculation. Or he may by the inoculation of a suitable vaccine develop a higher opsonic index, or higher resisting power, in his patient before he operates.

The value of the opsonic index does not end here. It may prove to be an important guide in prophylactic treatment. For instance, in tuberculous families investigation may show that their members have low tuberculoopsonic indices long before they have tuberculous lesions and that prophylactic oculations may raise their opsonic indices to a point within the normal tuberculoopsonic range or, in other words, increase their resisting power to a point of safety against tuberculous infection. Further, the opsonic index is helpful in diagnosis. For example, in a suspected pulmonary case a steadily low tuberculoopsonic index, or a tuberculoopsonic index widely fluctuating from a point below the normal range to a point above the normal range and vice versa, would confirm a diagnosis of tuber-

culosis. The opsonic index has aided in distinguishing pulmonary tuberculosis from malignant diseases of the lungs, chronic bronchitis and emphysema, bronchitis, and general debility. Here might be repeated the list of diseases already mentioned as the infections that have been successfully treated by opsonic methods; for in all these the diagnosis was made, or was confirmed, by opsonic index determinations before treatment by vaccine inoculations was begun. For another and a final illustration suppose the case to be an obscure arthritis and that the determinations give a record of a steadily normal tuberculoopsonic index and a steadily low gonococcoopsonic index. The diagnosis of gonorrheal arthritis is made with accuracy and certainty.

If the apparent value of opsonic methods in diagnosis, prophylaxis, and treatment, matters still in the experimental stage, however, is eventually confirmed, if the necessary special and minute technique is found not to be too costly in time and to be clinically practical, and if the personal equation of the operator can be sufficiently eliminated, an exceptionally promising field of work has been opened up for properly trained laboratory workers and clinicians. It must be said, however, that, although the apparent accuracy and reliability of the methods of Wright and his supporters have been fascinating and captivating, subsequent workers have developed a cloud of uncertainty through which the theory, technique, and practical results of opsonic methods are now widely viewed. To what extent this cloud may be dissipated time alone will tell. At present it seems to be generally accepted, however, that as a control to treatment opsonic methods require too much time to be clinically practical, while in the field of diagnosis they are more promising.

324 MONTGOMERY STREET.

A CONSIDERATION OF CONSTITUTIONAL INFERIORITY.*

By H. W. WRIGHT, M. D.,

New York,
Formerly Assistant Physician, Manhattan State He-pital, Ward's Island.

The subject involved in the title of this paper considered in its broadest sense would not only require much time and space, but would need the services of an experienced sociologist, psychiatrist, philosopher, and pædagogue combined in one. Broadly speaking, a vast majority of the human race might properly be called constitutionally inferior, the normal man being very rare indeed and a standard of perfection not yet having been attained

And then again every individual who becomes the victim of any of the many forms of insanity might be called a constitutionally inferior person, and

quite properly so.

Kraepelin deals with the subject in a very thorough and exhaustive way, from the psychiatric point of view, in his classification. However, he distinctly separates the ordinary types of insanity, such as mania, dementia præcox, melancholia, etc., from other types in which he recognizes some peculiar constitutional trait present in the individ-

^{*}Read before the Ward's Island Medical Society, Mir

ual constantly. These types of mental disorder he classifies as follows:

I, The psychogenic neuroses; a, hysterical psychoses; b, apprehensive neuroses; c, expectation neu-

2, Original traits; a, neurasthenia; b, constitutional pessimism; c, constitutional irritability; d, compulsive insanity; e, erethromania; f, impulsiveness, e. g., Wanderlust, Homicidal mania; g, sexual anomalies.

3, Psychogenic personality; a, congenital criminality or moral insanity; b, insanity of the emotions; c, dipsomania; d, habitual criminality; e, morbid lying, morbid faking; f, querulousness (habitual doubting).

4, Arrested mental development; a, idiocy; b, im-

becility.

You will see that this is a very comprehensive classification, but none the less an essentially correct one.

In this broad grouping we might also place the backward school children, who have recently been attracting more consideration, with happy results.

Other specimens of inferior humanity are familiar to us in the habitual truant, the vagrant, the hobo, the tramp, the "jack-of-all-trades," the street

tough and his gang.

So much for a general classification. Before going further it should be stated that the author of this paper has no intention of considering the lowest types of constitutional inferiority, namely, the idiots and imbeciles. The cases studied do not resemble either of these in any way, and therefore it will be unnecessary to make a distinctive diagnosis. The cases considered in this paper are types of individuals whom we can immediately place for convenience between the imbecile class and the dementia præcox group.

In the types of insanity mentioned above under Kraepelin's classification there is the possibility that after a prolonged study of individual cases, many would be found to be symptomatic complexes, of a certain stage in a deteriorating process, such as dementia, and not in themselves disease entities.

Is this true of all such cases?

Are these symptom complexes only transient episodes in "psychopathic," "constitutionally inferior," or "unstable" individuals (by whatever name we choose to call them), or are they definite steps in a deteriorating process? Herein lies the chief import of our study, because here our prognosis is involved, and correct treatment depends upon a correct prognosis. Are there any features presented by such cases whereby they may be distinguished from a præcocious dementia? It is upon this phase of the subject that discussion is requested. Kraepelin has suggested that if a thorough examination of the individual's entire history could be made we would find elements of early inferiority in all cases of dementia præcox, and Dr. Jelliffe has recently written a suggestive paper along the same lines in which he considers the "predementia" characteristics of dementia pracos, and shows that many of the traits found in patients whom it is customary to classify as "constitutionally inferior" are peculiar to thole in whom frequently a deteriorating psycho-1 develops

In order to arrive at any very accurate and valuable conclusions on this subject one should be in a position to analyze a large number of patients from the first inception of any abnormality until the natural death of the individual. Unfortunately it is very difficult to obtain so complete an analysis from most of the patients in this institution. Therefore we will have to be content with a brief consideration of a few cases (six in number), which have been classified as constitutional inferiority, after the patients had been observed for about three months in the hospital and either remained under observation or from whom recent information had been obtained of their condition since discharge. It would be manifestly of no value to attempt to draw any final conclusions from case records of patients who have completely passed out of our sight after only a brief residence here brought about by a transient episode causing their committal. Indeed, in looking over several such histories one finds that the patient has in some instances been again committed to other institutions and a diagnosis of dementia præcox made. I have therefore selected only a few cases in which the diagnosis is clear, having discarded many in which other elements appeared to

Before taking up individual cases it may be well to consider in general the nature of the inferior elements and the fields of human culture which are affected. Different parts of the complex human organism will be found involved in different individuals, but the basic elements appear to be the same in all. These elements are: I, In the first place the Defects of heredity; and, 2, secondary to this, or even aside from hereditary influence, Environmental defects, causing reversions to primitive types either nearby or far removed from the normal, the degree depending upon either one of the before mentioned influences or upon both together.

In the words of Groszmann, "these elements represent to this day mental, moral, and social instincts and activities on the savage, barbarian, or generally uncivilized level. They have been unassimilated by the civilization about them, they are representatives of primordial culture, of the beginnings of human society in all their crudeness. They do not fit into modern conceptions, and cannot be understood unless we apply a historic standard."

Of the two factors which constitute the ætiology of these elementary disturbances it is difficult to determine which is the more important. thought, the term constitutional inferiority would seem to imply of necessity an inherent defect to begin with. But this need not always be an inheritance of specific defects directly and in their entirety from parent to child. The human race as it exists to-day has inherited various imperfections of a lower order of creation from which it has evolved. We all have tendencies to animalism. What one of us has not felt at some time in his life the impulse or at least the capacity to commit all sorts of crimes against our neighbors or ourselves? and what has hindered these retrograde tendencies but the discipline of environment, involving as it does our fear of punishment and the desire for the respect of our neighbors? Under certain circumstances human beings tend to revert to a lower grade of moral, intellectual, and physical culture, just as domesticated plants and animals revert to wildness under the

proper environment.

It is this aspect of the ætiology which gives us hope for the prophylactic and curative treatment of such conditions as we are now concerned with. While heredity is a strong factor, environment should also be given an important place in the ætiology of constitutional inferiority.

For example, take the case of any city child whose parents are so busy earning their bread that they can give the child little or no instruction in morality and no supervision whatever. quently the child is running in the streets when not in school, and the corrective influences of the school is reduced to a very small proportion, because the child is placed on a "part time" class schedule, thus being allowed to roam the street half of the day, associating with all sorts of people, acquiring lawless habits which lead him to petty crime, later to more serious misdemeanors—then follows juvenile asylum -and after that the bad habits may have become so strong that the career of an habitual criminal is firmly established. Would you say that heredity is the chief cause of the trouble?

Just as in physical diseases we have both predisposing and exciting causes so we have in mental disorders. Those who are predisposed to tuberculosis by heredity do not always become infected with tuberculosis, there must be also the exciting cause and the unhygienic surroundings, in other words,

the tuberculous environment.

Inferior moral, intellectual, or physical qualities may be acquired as well as inherited, so also may their opposites be attained. The fact that they are only acquired does not make them any the less constitutional. Character, good or bad, is largely the result of habitual reactions to environment, not altogether an inherent thing, although it must be admitted that the type of reaction depends to some extent upon the inherent traits. To determine which is the more important factor offers a fruitful field for speculation and experiment.

We may safely summarize the ætiological element by saying that they are exaggerations of normal, universally constitutional tendencies, becoming manifest in certain individuals because of their lack of inhibition, this lack being due both to unfavorable environment and to hereditary defect.

Of the cases under consideration all are those of women, and in them, as would be expected, the animalistic reversions are not as pronounced as in men. On the other hand, we find the psychopathic elements more refined and complex because of the special environmental influences to which those of the fair sex are subjected. Furthermore, according to the inherited or acquired traits peculiar to each individual will the type of inferiority be manifested, so that either the moral, intellectual, or emotional field may be chiefly involved.

The cases selected illustrate some of these different types, there being representatives of the lowest grade in which the emotional field is chiefly involved and of the higher grade involving a restrict-

ed portion of the intellectual field.

Consideration of Six Patients.

Of the influence of heredity our information is meagre and not altogether reliable. It should be remembered that hereditary influences may be more distant than inquiry has been able to ascertain. Abnormal traits are known to skip one or several generations to appear later in another. However, we find hereditary taint in some form, either of actual insanity, alcoholism, or neurotic constitution in five of the six patients.

Of the influence of environment our information

is more significant.

In one case the mother of the patient died during the latter's infancy, an epileptic stepmother and a "weak minded" father reared the child without any discipline whatsoever in a home lacking comfort, peace, or moral influence either by precept or example; public educational advantages were also denied, and physical handicap was another factor in producing a constitution marked by absence of moral or intellectual strength. A second patient had a home life very similar to that just described, cruelty and neglect leading the patient to involuntary prostitution at the age of fourteen years, this becoming later a voluntary method of existence for several years. Later on this patient was rescued from her associations by reason of her commitment to this hospital, and on her discharge obtained a decent position in which she is now doing well. Another patient had all the advantages of a refined home, with a good education; she inherited an impulsive neurotic nature, which manifested itself by an elopement with an unworthy lover after three days' courtship; the match proved disastrous in that she was infected with syphilis, and, leaving her husband, she has since led a wayward life. fourth patient had a good home in most respects. but lost her mother at an early age, could not agree with a stepmother, and left her home soon after puberty to shift for herself. In another case the patient suffered from a lack of proper parental discipline, and eloped at the age of seventeen with a married man, who refused to marry her in the legal way even after divorcing his first wife. The sixth patient was an invalid from birth on account of a spastic paraplegia, and was therefore influenced by a narrow, self centered mode of living, having little to interest herself in, with every whim pampered. A hypochondriacal type of psychosis with obsessions developed.

Time of onset of the earliest noticeable abnormality.—This is found to have occurred before puberty in four patients, and just at puberty in two. In all the patients studied there were, as would be expected, aggravations of previously existing traits at puberty. Many eminent authors have laid special stress upon this period of development in relation to insanity and to the formation of constitutional habits—the formation of character. Down (Montal Affections of Childhood and Youth) says "as puberty approaches attacks of mental aberrations assume a special character, . . . especially if there is any sexual deviation." To quote Stanley Hall, "destructive energies are now vented, there is a passion for creating trouble by mischief, great eleverness in concealing faults by lies, no natural

affection, and no conscience, yet even these cases after the troublous period of transition has passed often settle down to respectable and fairly decent Fuchs in his work, Schwachsinnige Kinder, says, "while the stage of puberty is revolutionary for normal persons it is still more so for defectives; idiots animalize, imbeciles become violent, egoistic, coarse, and vulgar, and the weakminded grow unsettled in their normal feelings and are without resistance to sensations that now erupt within them." Again, Stanley Hall says: "Many children thought normal before are first found wanting at this period. They are neither silly nor half-witted, but can no longer fully profit by school; their educability ceases, they begin to suffer from the provocations of those more intelligent than themselves, and become dead weights in their classes because their period of docility is ended. . . . The momentum of heredity is often insufficient to enable the child to achieve the great revolution of puberty. . . . There is not only arrest, but perversion to a darker remoter stage to which the child harks back." (Adolescence, 1905.)

Such being true, it is not surprising to find that in some of our cases the individual was considered a normal child until about the age of puberty, and this does not rule out our diagnosis by any means.

Mode of onset.—It is noticeable that in the patients under consideration the onset of the episodes has been sudden and characterized by an aggravation of previously existing abnormal traits as an expression of a reaction to some definite external stimulus. These reactions do not always constitute a psychosis sufficient in duration or intensity to require commitment to an institution, and are often transitory, episodes quickly recovered from and leaving the patient in as good a condition as previously. In contradistinction to this mode of onset and type of reaction, how different is the mechanism of dementia præcox, in which we find a gradual onset of a disintegrating process often recurring amid a favorable environment, often unrelated to any specific external cause, but rather to some autopsychic difficulty or source of irritation and disassociation; and, furthermore, a progressively downward course without complete recovery to the previous standard of efficiency.

In all but one of our patients there is a history of sudden episodes, of impulsive conduct caused by some real external circumstances such as a fright, a disappointment, a quarrel, seduction. In the one patient in whom such a history is absent there are definite symptoms of psychasthenia with fixed ideas of a somatopsychic nature; although inferior traits of another kind were present in this patient in early years, the psychasthenia symptoms did not appear until the patient was about thirty years of age. This suggests that in psychasthenia we have a more definite disease entity, a more clear cut condition.

Symptomatology.—The symptoms presented by these patients taken together as a group may be summed up in four divisions: I. Abnormal selfishness; 2, abnormal irritability; 3, abnormal suggestibility; and, 4, abnormal mental fatigue.

In such patients abnormal selfishness is manifested by cruelty and unscrupulous conduct when the personal interests may so be favored; lack of natural affection and affection unnaturally directed; general disrespect for any authority. These traits are prominent in the habitual criminal.

. Abnormal irritability gives rise to impulsive acts,

violent episodes, and unstable emotions.

Abnormal suggestibility is a prominent factor in the cases presenting fixed ideas and phobias, in psychasthenia, in those having hysterical symptoms, in those subject to hallucinations (one patient had an episode of depressive hallucinations). Such a condition causes the individual to be easily frightened, easily excited, and also gives rise to morbid lying. Abnormal mental fatigue is manifested by a lack of steady application to any task requiring thought, an inefficiency for commonplace occupations requiring any degree of concentration or responsibility, and is early seen in the defective school child, in the vagabond, the habitual idler and rover: later on in life such people are found to be still unsettled in any permanent occupation and are unable to hold any position for long. They are also unable to reason things out for themselves, and are apt to take the quickest and easiest method of forming an opinion, namely, that method which is first suggested by their emotions. Two of our patients illustrate these defects very well; in both of them, however, there is the handicap of physical inferiority. In none of our patients considered is there a marked absence of intellectual power such as is found in the imbecile class. On the contrary, in three of these patients there is a precocity of intellect having a wide range of interests, but all showing a lack of concentrative and applicative power. In none of them has there been at any time any impairment of orientation or memory, or grasp on previously acquired knowledge, unless we except one case, where there was a transient hallucinosis and condition of fright leading to misinterpretations. Incoherence in expression of thought was absent in all.

Course and duration.—As to the course of the condition while under observation; in all but two cases the patients recovered quickly from the episodes which required their committal. The two patients in whom the psychosis was protracted showed symptoms of psychasthenic insanity with more or less fixed ideas. In one of these two the condition was much improved by persistent argument, for she was an intelligent person with excellent insight, but she has now again relapsed after an emotional upset due to natural causes. In both of these patients having a chronic course relapses have been frequent both in and out of the hospital, but temporary recovery has always been complete, so far as relief from their morbid ideas with insight is concerned. In some patients aggravations in the form of fresh episodes have occurred in the hospital, and have always been due to some tangible external cause, e. g., a refusal of discharge, a morbid suggestion from a fellow patient.

In all the patients the emotional reactions have been consistent with the thought content through-In all of them there has been manifested a certain amount of insight into their condition as soon as the acuteness of the episode has subsided, and later on the majority of these patients have acquired insight of a marked degree.

Recovery to the previous standard has occurred in four of the six patients. In the remaining two

obsessions and fixed phobias are present, and in them the prognosis remains doubtful, especially as they are now in the involution period. However, we may say that in the majority of cases the prognosis is good when the patients are placed under a proper environment. (It is questionable if an insane asylum is the ideal environment.)

The distinctive diagnosis.—As to the distinctive diagnosis it will be found most often necessary to distinguish these cases from dementia præcox. This is usually difficult upon the initial examination, and several months of observation are necessary before a satisfactory diagnosis can be made, and even then in some cases we may still be left in doubt.

From a study of the cases selected the most helpful distinguishing points so far developed may be

enumerated as follows:

I, A reaction to some definite cause, usually allopsychic, this reaction being somewhat similar to the normal, but different in that it is an abnormally exaggerated type of reaction such as would not occur in a well balanced individual; i. e., a reaction to environment, not an autopsychic disintegration of

2, Frequent occurrence of such reactions which subside with removal of the exciting cause and leave the patient unchanged from the usual stand-

ard; i. e., absence of deterioration.

3, A history of abnormalities of condition from an early age, the individual never having been considered quite normal. This is contrary to the usual history of dementia præcox.

4, No loss or impairment of that part of the intellect having to do with memory, orientation, and application of previously acquired general knowledge.

5, No marked affection of the sensorium.

6, No marked incoherence or blocking of thought or dreamlike condition accompanied by fantastic delusions or disassociations of personality, such as manifested in katatonia and other forms of dementia.

From idiocy and the low grade or average type of imbecile it seems unnecessary to take up much time in making a distinctive diagnosis. The cases selected do not correspond with our present conceptions of imbecility in any marked respects. The inferiority in the cases under discussion is not a general inferiority, but is more or less localized in one sphere of the individual's constitution and is manifested differently in each case.

Before closing I would like to read briefly a synopsis of the history of one patient who seems most typical of the conditions we are studying, and

then say a few words as to treatment.

ELSA A. Was admitted May 29, 1907. Family history: Father, normal; mother, a consumptive; paternal grandfather, intemperate and of very violent tem-per; a sister hysterical, often threatened suicide. Present history: Patient was considered a normal child

until about the age of fourteen, when she became irritable and was so insubordinate at school that she was expelled Then she obtained work in a factory, but was dicharged soon because of impudence to the foreman. Later she took up domestic service, but has never held one position for long. At the age of seventeen she was told to leave her house and never return, after having quarreled with her father. She never got on well with him or with her sisters. Her mother died in 1905 while she was living away from home. In her habits she had been abstinent both as to alcohol and sexual indulgence. She twice attempted suicide with poison. The remainder of her history is obtained from the patient. She told us that for several years she had found it difficult to get on with people, that people never had treated her with enough consideration, that their kindness had only been superficial and had failed her when she most needed it. This hypercritical attitude of mind toward things in general had been a prominent and constant feature. When these feelings dominated her she said she felt capable of letting loose her resentment in violence, had difficulty in restraining herself, and in short felt as if she were "a devil." At times her insight was very keen and she then realized that she was defective in her judgment, but never entirely overcame the feeling that the world had used her badly and that she might have been different if her surroundings had been otherwise.

The following circumstances led to her commitment:

For a few weeks previous she had become rather careless as to the future and had been going to the theater with chance male acquaintances, picked up on the street, but had committed no other impropriety. Later at a religious had committed no other impropriety. meeting she became excited because of having discussed the subject of the evening with the preacher so vigorously as to put religion in a bad light. The same evening she was followed while under this excitement by some young men of the street, also pursued so long that she became very frightened, ran to a police station, and there acted so peculiarly (begged to be killed) that she was transferred to Bellevue. There she was quiet and indifferent, said she wished someone would kill her. Her excitement soon subsided, and on admission to this hospital she was quiet and agreeable, talking freely of her past life in a rational manner, showing no delusional formation or incoherence. No defect of memory or orientation or grasp on general knowledge. Her insight at this time was excellent; she realized that she had behaved abnormally and explained her behavior sensibly. Physical examination showed nothing abnormal. Her conduct remained normal for about two weeks, when she began to fret at her detention, saying that no matter how well behaved she wasn't allowed to that no matter how well behaved she wasn't allowed to go out. Then suddenly one morning she refused to work, threw herself on the floor, became mute and resistive for several hours; later told a nurse that she would show us how she could make things go, and "what trouble really was," that there was no use of working here because they only kept her the longer. The same day she became violently angry, screamed and kicked and required much restraint. The next day she was quiet and spoke regretfully of her behavior. Three days later another similar episode of anere with malicious profane talk and requests to be given ger, with malicious, profane talk and requests to be given poison. She said she would never be let out and therefore wanted to die, was not crazy but had a bad temper and wanted to die, was not crazy but had a bad temper and people didn't understand her. Her excitements were always followed by remorseful depressions. After some weeks of normal conduct she was discharged in care of "after care" agent, and a position obtained for her in the Shakers' Colony at Lebanon. She remained there about two weeks and then returned to her stepmother, leaving because she found no means of amusement there.

After returning from Lebanon she was depressed. A position at Poughkeepsie State Hospital as waitress was obtained for her, but she had difficulty in getting along with the other girls and left because, as she said, they treated her meanly and "thought themselves above her." Then a position at general housework was obtained for her. The night before going to this place and while her stepmother was urging her to get her clothes washed and other things ready, she suddenly screamed and angrily declared that she did not want to work there. She quieted down, however, and not want to work there. She quieted down, however, and went to the place, remaining there only half a day, because she thought the mistress imposed upon her. Then another place was obtained for her, in a very congenial family. She got on well and was liked until the family began to make preparations for moving, when she because of the necessary increase of work, and she had to be disnigged.

she had to be dismissed.

she had to be dismissed.

She was at home for a week thereafter, during which time she was restless, said the devil must be in her—spoke much of the ill treament of the poor by the rich, as indeed she had often done before. She would suddenly run out of the house and down the road to a nearby brook with thin clothing on to bathe her feverish face and hands. Under medication she quieted down, and another place was found for her. This place she found very pleasant. Her employers treated her unusually well, she liked them at

once and became unusually elated in consequence. Went much to religious meetings at this time and went back one night to the church where she had once before created a disturbance, and there denounced the pastor and his congregation as hypocrites, saying that they did not practise anything they preached, etc. She went home the same evening much excited, but was quieted by her father and promised not to act so again. A few days later, she was again noticed to be restless and elated, and went to a salvation army meeting, telling her mother beforehand that she was going to join this society, because she felt she would be a great preacher.

While in this meeting she created so much disturbance that the police were summoned. They took her to Harlem Hospital and made preparation to transfer her to Bellevue Hospital the same evening. While she was in the ward she took advantage of the nurse's absence for a moment to seize a bottle of carbolic acid from a medicine closet and drank its entire contents. Before her death she had a few conscious moments, during which she said she had acted on

impulse only.

Treatment — In regard to treatment I have only a few words to say in general. It is easy enough to say that since we know the ætiology of those conditions, namely, bad heredity and bad environment, let us remove the causes. With the factor of heredity, which, after all, is most probably the prime factor, not only theoretically, but literally, we as physicians, as institutional workers, can have little to do.

But it does seem that the other factor in causation of constitutional inferiority should concern us

very much.

How many times in this institution we come in contact with cases in which we feel that the patient does not really belong here, that it is a great pity for them to be here, and yet it would be a greater pity to send them out into the world—into the environment from which we have received them.

Therefore I believe that there should be a special kind of institution adapted to these cases; an institution on a small enough scale as to size, so that individual treatment may be given for individual needs, so that individual capabilities for one or another kind of work may be developed. In such an institution the physician would be of less use than the instructors in manual training, physical culture, or ethics, and would be simply a consultant. such an institution severe reformatory discipline would be employed in some cases, in other cases kindly correction and instruction through constant personal contact would be used. In no case would the patient be treated only collectively, only in the mass, but instead, particular attention to particular needs would be the rule. By such methods we would prevent that distressing and deplorable condition so often occurring in institutions, namely, deterioration in interest, in habit, and in initiative, facts which are due to treating people in classes, as machines instead of as individuals.

There is nothing so helpful to those having retrograde tendencies as stimulating their interest in some special sort of employment for which they show a liking or capability and giving them the opportunity of exercising that interest. In the type of person we are considering this is not an impossibility. The chances of good results by such methods would be especially favorable when the treatment had been instituted during the years of adolescence, for this is the plastic period. After a period of institutional training the individual could

be safely placed out in the world again, providing a proper home life or surroundings suitable in other

respects were secured.

Such treatment is prophylactic as well as curative when the individual is placed under control during adolescence. The ideal institution would take the place of a good home training in the most thorough sense of that term, which is what most patients of this type are denied, and a good home life during the plastic years will wipe out many of the defects of heredity, if not all of them.

SOFT TISSUE ROENTGENOGRAPHY.*

By Henry Hulst, A. M., M. D., Grand Rapids, Mich.

Soft rays, an exposure long enough to insure a "well done" plate, the tube adequately shielded, a small calibre diaphragm compressing and holding rigidly immovable the object, a rather slow plate of maximum latitude, together with a clear working contrasty developer—such are the elements of the technique of the röntgenography of hard tissues.

As a result, good bone pictures are now so much the rule as to excite little interest beyond that of

their clinical value.

The density differences of soft tissues being very much less, their röntgenography is proportionately more difficult. But the well known inferiority of soft tissue röntgenographs and the scarcity of good ones is not entirely accounted for by this inherent difficulty alone. Another cause and a less insuperable is external to the object and lies with the operator himself.

"Not by shortening the time of exposure, but by selecting less penetrating rays and stronger currents the röntgenography of the future will secure its better results"—such is the gist of Holzknecht's recent prophecy. It is nothing but the technique outlined above and designated there as hard tissue röntgenography. Stechow's "better expose too long than not long enough" is to be taken in the same sense as Holzknecht's dictum, and is likewise intended as a universal method. Though Albers-Schönberg holds contrariwise that "over exposure is the most common error," he, too, favors as a general rule "a thoroughly done picture with a rather long exposure."

The purpose of this paper is to point out the inadequacy of such a technique and the necessity of modifying it to suit the requirements of the tissues

themselves.

To obtain a structure picture of the bones of the body we may within certain limits compensate for increased softness of tube by the use of stronger currents or longer exposure or both. But for the risk of burning the patient much softer tubes might advantageously be employed in this kind of work than are ever made use of now. For it is not easy to lose a bone by too long an exposure or too strong a current if only the tube is soft enough. But as soft rays reduce more silver than those that are more penetrating, long before the bones are done the soft tissues may have been rayed into utter dark-

^{*}Read before the Fourth International Congress on Medical Elect.ology and Radiology, held in Amsterdam, September 1 to 5, 1908.

ness—the softer the tube and the stronger the current or the longer the exposure the greater will be the damage done to the soft tissue part of the picture. To reproduce the soft tissues and even such comparatively hard tissues as the heart, stomach, and colon containing bismuth, calcified glands, or dense calculi, the tube must not be too soft.

The routine employment of the softest possible tubes on all occasions and for all purposes within the limit of safety to the patient, as Holzknecht recommends, is a temptation not easy to escape. This is the way to make brilliant pictures, and brilliant pictures are always striking at first. The uninitiated will instantly prefer them to those made with a somewhat harder tube. But brilliancy, contrast in a röntgenograph is what emphasis is to wealth of meaning in rhetoric. The brilliant contrasty picture made with the softest possible tube is exceedingly emphatic; but examine the soft tissues and no "meaning" is there. The pictures are brilliant be-cause the soft tissues are black, they are emphatic because they have no meaning, as soft tissue pictures they are bad because the tubé was too soft and the exposure too long. Contrast, emphasis, though more striking at first than detail and meaning, in röntgenography as well as in other modes of reproduction and expression, represent the earlier stage of their evolution. The first period of röntgenography, the period of screaming contrasts, passes over into that of detail in soft tissues. The indiscriminate use of the softest possible tube is now regarded as a bad habit. Röntgenography, instead of getting into a rut and thus retarding progress, by adopting a one horse rule becomes a flexible method, röntgenography, of hard tissues naturally leads to that of soft tissues as well.

But more than this is needed. To röntgenograph the apices by means of a one minute exposure, the patient breathing all the while, violates another not less important principle. Nor is it made good by the use of an imposing compression diaphragm. The object must be at rest if possible. In the case of lungs, kidneys, and other abdominal organs this requires at least cessation of respiratory movements during the exposure. The heart is never entirely at rest. The respiratory movements of the heart, however, are the most disturbing and should always be eliminated. This does not require the exposure to be made very short. And if the necessity of the object being at rest constitutes the only as well as the most obvious reason for shortening the time of exposure the difficulty is not great. In that case Levy-Dorn's two seconds for lungs are probably short enough and his six seconds for hips, which d not breathe, might well be sixty.

I believe, however, that there are other less obvious reasons for shortening the time of exposure in soft tissue röntgenography. The following observation, made *en passant* by Albers-Schönberg, indicates, though unintentionally and unwittingly, the advantage of the shortest possible exposure. It reads simply like this: "The underexposed plate shows remarkably clear detail." Indeed, not until the hard tissue röntgenographer begins to look for soft tissue details does he learn to forget the bones. Until then, ideal soft tissue pictures must look to him like under exposures. Levy-Dorn asserts that he was

the first to demonstrate a picture of the chest taken during suspended respiration in October, 1897. But this was only to avoid disturbance of motion. Genuinely short exposures were first described, I believe, by Dr. Rosenthal in 1890.

In 1901 such pictures were published in a work to which I refer with gratitude as epoch making in the history of soft tissue röntgenography: Dié Röntgographie in der inneren Medizin, by Professor H. H. Ziemssen and Professor H. Rieder. The first pictures of the lungs and heart made in America by one second and shorter exposures without the use of intensifying screens were demonstrated by myself at the meeting of the American Röntgen Ray Society, held in Chicago in 1902.

Intensifying screens do shorten the time of exposure. But the purpose of the short exposure being to secure detail not otherwise obtainable and intensifying screens being contrast makers, that is, detail destroyers, their employment in soft tissue röntgenography mistakes the means for the end. In röntgenography of the heart, in which we care for detail less and for contrast more, they are useful makeshifts; and the usually "oversensitive sigma plate" may be sandwiched between two screens and not be fogged as usual, provided the plate is sufficiently far from the target.

In Europe, as well as in America, I find it is quite commonly supposed that extraordinary apparatus is needed for making very short exposures. Yet, my first one second and shorter lung pictures were made with my old fashioned 18 inch (45 cm.) coil designed to be operated with a hammer break, but run on an extemporized Wehnelt interrupter. After six years of experience with this method I am more than ever convinced that any good 16 inch (40 cm.) coil and some of considerably shorter spark length. if properly interrupted and adjusted, can be utilized to cut down the time of exposure of an ordinary lung at 20 inches (50 cm.) to one second and less without recourse to intensifying screens.

But coils are not the best kind of instruments. I have a coil that can be made to give a heavy 38 inch (95 cm.) flame which permits the exposure to be shortened to a single flash. But the high tension. high amperage current thus passed through the tube quickly bores a hole in the target of any tube. For this reason alone, if there were no others. I prefer a machine I have had constructed especially for very heavy work. The picture of it on the screen shows that it is a static machine. It is of the Töpfler-Holtz variety, but perpendicular instead of horizontal. The rotating plates are made of shellac and mica, which have been tested to 7,000 revolutions per minute. You can count fifty such, 28 inches (70 cm.) in diameter. The fifty stationary plates. split through the centre, are of glass and measure 32 inches (80 cm.) in diameter. The hexagonal cabinet is strongly built, and supports on top the 5 horse power motor coupled direct to the shaft. The combs and brushes are gold plated. The electrical current furnished by this apparatus differs from any ever seen before. Through a Walter six tube it registers about 12 milliampères on a Snook meter. the plates revolving 1,800 times a minute.

The full discharge passed from a positive point to a negative disc measures about 16 inches (40 cm.)

in length and is a noisy torrent of white sparks. But when the disc is made positive and the point negative an interesting change occurs. A noiseless flame curls with a sweep backward and upward toward the negative point. This flame, unlike those seen from less powerful static machines, is not purplish in color, but yellow, like that from a powerful coil.

Two seconds is enough for a renal calculus in a heavy person. For a picture of suspected phthisis I merely flash the tube. On a sigma plate sandwiched between two tungstate screens the heart is teleröntgenographed at ten feet (three metres) without fogging in one second. The stomach and colon can be done in one second (without screens), but as the bismuth mixture used places this work under the category of *hard* tissue röntgenography, I prefer to use a tube called very soft by Albers-Schönberg and to lengthen the exposure to five seconds after expiration.

Examination of the tube energized in this manner reveals the remarkable fact that there is no strain. A delicate water cooled Müller run for thirty seconds (six times the maximum exposure needed for anything) showed an unspotted target. This cannot be done with a coil, nor with a low tension high ampèrage transformer such as have recently appeared; in fact, I know of no other instrument in existence with which this can be done.

The extremely short exposures which suffice for the work requiring the greatest current, and the perfect ease with which a fine delicate tube transforms such a current into Röntgen rays, proves, all other things being equal, the vast superiority of a really adequate static current in Röntgenology over all others hitherto employed.

SEVERE IVY POISONING.

By Ralph Francis Ward, M. D., New York.

Those pathological changes in the skin of susceptible individuals from poisoning by ivy (Rhus toxicodendron), poison oak (Rhus diversiloba), or the poison sumach, are known as dermatitis venenata.

Individual susceptibility or immunity plays the decisive rôle in this condition more strikingly than in almost any other. As a rule, dark complexioned individuals are slightly less susceptible than blonds, although this is not to be relied upon. Some individuals are absolutely immune to the poison, and can work in and handle the poison ivy, and can crush and rub the leaves and berries upon the face and body, without experiencing the slightest symptom of cutaneous irritation. Others can expose themselves by handling and otherwise coming into contact with poison ivy and will experience a moderate itching at the site of a fresh scratch or other fresh solution of epidermal continuity. Still others, slightly more susceptible, will have an erythematous welt or a papule representing the exact contact with the vine, which, after itching and burning for a few days, will gradually disappear, without having extended or being carried to any other part of the body. Those who are slightly susceptible, as those described before, rarely present themselves to us for

treatment. I shall describe only the acutely sus-

ceptible.

Of these some are so sensitive that, being near where poison ivy is being cut, or burned, or having the wind blow over the vines onto the individual, will excite a severe attack. This is, however, rare, as an actual contact with the vine is usually necessary. Cases have been reported to me where gloves and shoes worn in the country and handled by others after their return have produced an attack. Rainy and hot, humid days are more favorable for producing poisoning than dry hot or cold days. Free perspiration or a wet skin aids inoculation. Toxicodendric acid is the actiological factor, which

is no doubt combined with volatile oils.

The most common portions of the body affected are the extensor surfaces of the hands and forearms, the face, and the legs, although any part of the body except the soles of the feet may be affected. One patient of mine was affected from the hair line of the scalp to the soles of the feet. Upon the palms of the hands were vesicles beneath the thick epidermis as large as hazel nuts. From hands that have come in contact with the leaves, stems, or berries, all of which are poisonous, it is often carried to the penis and scrotum, or the breasts of the female. I have seen the penis enormously and greatly distorted, and the scrotum attain the size of a large double hydrocele. These parts react more actively than the exposed parts, and because of the great amount of loose areolar tissue, makes extensive ædema possible.

The pathological process is a true dermatitis, the entire derma being the seat of a severe inflammation, and characterized by heat, swelling, and redness. There is at first an erythema, with some thickening of the skin, which appears a few hours after contact. Upon this base papules form, which rapidly fill with serum, while the skin below is becoming more cedematous. The vesicles may remain discrete, but usually become confluent, and rupturing, leave great, oozing, raw areas. By this time the skin has become so cedematous that affected arms or legs will be twice their normal size, and if the head and face are involved, the features may become as unrecognizable as in severe facial erysipelas, the cedema making the head and face round, and completely closing the

yes.

From the beginning itching, tingling, and burning are constant, and if scratching is indulged in, will lead to tearing of the skin and anguish almost crazing the patient. Night has its terrors unless

proper treatment is established early.

The course of the disease depends upon the extent of surface involved and upon the treatment followed. In general, in robust patients, after taking from twenty-four to forty-eight hours to reach its height, it will begin to subside in two or three days more, at which time the weeping rapidly subsides, the edema goes down, and the fiery red becomes a dark purple, resembling in the legs an old healed varicose eczema. The parts assume their normal proportions in three or four days after the weeping has stopped. Desquamation begins and continues until all the affected parts have shed their epidermis at least twice. It may peel off in strips, or be shed in scales, or a branny desquamation may appear.

Constitutional disturbances are not great, consisting of nausea and vomiting at the height of the oozing, and slight afternoon and evening rise of temperature, not often exceeding 101° F.

bowels are constipated.

The diagnosis is not difficult if one has seen typical severe cases. When the face alone is the seat of the inflammation it has to be distinguished from facial erysipelas, which extends peripherally with a red, raised edge, and is accompanied with grave constitutional disturbances. If some other part of the body, as the arms, are affected, and the patient has been in the country, the diagnosis is unmistakable. From eczema it is easily distin-guished because of its rapid development, great accompanying ædema, and vesicle formation.

The abortive treatment consists in the application of lactic acid, one per cent., in ethyl alcohol, ninetyfive per cent., to the exposed parts just as soon as there is any tingling or reddening. It is evident that this cannot often be employed, but it is of great value in preventing the inflammation in secondary areas. This is used also by those who have suffered and wish to be armed against and able to begin successful treatment of a possible new inoculation.

It has often been stated to me that those who have had a severe poisoning are thereby rendered more susceptible. I have not found this to be the case. The fact is that those who have had a severe poisoning are always careful of any itching of the skin

and treat it as a possible poisoning.

The treatment consists in putting the patient in bed and giving calomel in divided doses, followed by a reliable saline. This is of the utmost importance in relieving the system of all possible intestinal toxines. As constipation usually exists while the patient is in bed, simple salines should often be used. Large draughts of cool water should be given to keep the kidneys well flushed out, as additional work is thrown upon them in proportion to the extent of skin involved. If the abortive treat-·ment has failed, which it will unless inaugurated very early, or if the patient is not seen until vesicles begin to form, a lotion of the saturated solution of aluminum acetate applied to the affected area upon very loose gauze dressings and kept well wet with the solution, has, in my hands, been more efficacious and comforting to the patient than those mentioned below, which are commonly used. New dressings have to be applied at least three times daily, on account of the excessive weeping. Under no circumstances do I substitute ointments at night during this stage. The wet dressings are continued day and night until weeping stops. Solutions of phenol, two to four per cent.; sodium bicarbonate, sodium sulphite, lead acetate, lead and opium wash, or black wash may be used if aluminum acetate is not at hand. When the weeping subsides the wet dressings are discontinued and an ointment of ichthyol, ten per cent., in petrolatum, is applied. I have found this the best ointment to use.

While the patient is in bed I give two to five drops of the tincture of cypripedium every three hours. After the acute symptoms have disappeared I give the same dose three times a day, after meals, continuing thus for two weeks. This aids the kidneys and stimulates healthful repair of the skin, and very markedly lessens the tendency to post inflam-

matory itching and burning.

Under no circumstances are the surfaces rubbed or the vesicles evacuated. I have seen slight rubbing during dressings set up violent burning and intolerable itching, requiring a hypodermic injection of morphine. When sleep is disturbed because of peripheral irritation I give codeine sulphate, gr. ss, at bed time, and repeat during the night if neces-

The diet should consist of milk and vichy or some other carbonated water, equal parts, alternated with simple, salt seasoned broths, and a few light vegetables. For two weeks after the local manifestations have disappeared I keep the patient on a strictly vegetable diet. Experience has taught me that meat given before this may cause a disagreeable return of cutaneous irritation, which often is most manifest when the air strikes the skin upon removing the clothing before retiring, and may not subside enough to permit a good night's sleep.

Sequelæ are often wanting entirely, but occasionally eczema or furunculosis may supervene. It is therefore wise to give a hæmatonic consisting of some form of iron, arsenic, and strychnine, beginning as soon as the patient is up and around.

205 WEST ONE HUNDRED AND FIRST STREET.

Our Renders' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXXI.—How do you treat chrone : and Closed

LXXXI.—How do you treat chrome rema? (Closed December 15, 1908.)
LXXXII.—How do you treat chronic lead poisoning?
(Answers due not later than January 15, 1909.)
LXXXIII.—How do you treat acute dysentery? (Answers due not later than February 15, 1909.)
Whoever answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short: if practicable, no one answer to contain more than six hundred roords.

All persons will be entitled to compete for the prize whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

Our readers are asked to success topics for discussion.

The prize of \$25 for the best essay submitted in answer to question LXXX has been awarded to Dr. Paul F. Ela, of East Douglass, Mass., whose article appears below.

PRIZE QUESTION LXXX

THE TREATMENT OF ASPHYXIA NEONATORUM.

BY PAUL F. ELA, M. D., East Douglass, Mass.

Asphyxia neonatorum is very commonly met at close of prolonged or complicated labors. A discussion of its ætiology and prophylactic treatment might extend through the entire art of obstetrics considered from the standpoint of delivering a child capa

ble of breathing.

During the labor itself, the rate of the fetal pulse should be watched and if it becomes permanently slow, delivery should be hastened. In breech deliveries I cover the legs and body with warm cloths to prevent the difference between the temperature of the birth canal and that of the room from exciting premature efforts to breathe, and when the head reaches the perinæum I retract the vaginal wall from contact with the face to allow access of air to the mouth. In cephalic presentations it is sometimes necessary to slip a coil of the cord over the child's head or even to cut the cord in order to hasten delivery. In any case the face and air passages should be cleared of mucus as soon as the head is born.

The quickest way to clear the nasal passages is to attempt direct inflation of the lungs by the "mouth

to mouth method."

The diagnosis is made from the fact that the child does not breathe. The pulse is slow and its quality may range to any degree of weakness. The skin may be livid or deathly pale. The reflexes may be abolished.

The treatment should aim to clear the air passages, secure inflation of the lungs, and preserve and in-

crease the child's vitality.

The most certain method of filling the lungs with ais is by direct inflation through a catheter passed into the larynx. Mouth to mouth inflation in my own experience results in distending the stomach. In either method the nostrils should be closed. Artificial respiration by flexion and extension of the body is also effective. In the Schultze method the shoulders are grasped from behind with the child upright, and then the child's body swung at arm's length forward and upward until at the top of the swing the motion is abruptly checked, and the legs and pelvis fall toward the operator compressing the thorax. Reversing the motion the body extends and the thorax expands. This is said to be the most effective of the flexion methods.

In case the reflexes have not been abolished, the application of cold to the skin, slapping the buttocks, blowing in the face, tickling the throat, any of them may arouse the breathing reflex. Most effective is exploration of the anus with a finger.

One or two tablespoonfuls of blood may be allowed to escape from the cut cord if it seems neces-

sary to relieve the circulation.

These methods will generally be successful in simple asphyxia with a blue skin, bounding heavy pulse,

and good muscular tone.

But sometimes a child is born in a state of shock. As the body is delivered into his hands the attendant will perceive the flaccidity of the limbs before his everecognizes the cutaneous pallor which may not be evident at first. All methods of resuscitation which depend upon the excitability of the reflexes will fail in such a case because the reflexes do not exist. Even artificial inflation of the lungs is a desideratum secondary to the imperative need of preserving and restoring animal heat. If the cord still pulsates and artificial heat can be supplied while this connection with the aerated placental blood is maintained, I believe it is better not to cut the cord at once. But the inconveniences in the way of maintaining animal

heat under such conditions will usually determine in

favor of cutting.

Where I have reason to expect an asphyxiated child I have a pail of water at 102 to 105 F. ready and after a single compression and relaxation to inflate the lungs if possible, if shock is present, I immerse the body to the neck at once. One such folding of the pelvis on the thorax, the body supported head downward, can be practised even before the cord is cut. The position favors drainage of fluid from the air passages, and a moment is saved as compared with the Schultze method, which I have been afraid to use in such a case. A form of artificial respiration may be practised in the warm bath by alternately raising and lowering the thorax by one hand under the shoulders, the head and feet of the child being allowed to hang free, or direct inflation can be tried.

If the heart continues beating it should be left alone. If it stops, the fingers of the left hand can reach it through the flaccid abdominal wall and compress it gently against the thoracic wall. It can

sometimes be aroused again.

In a favorable case the slow pulse will quicken, the child will gasp spontaneously, and the skin assume the livid color of "blue asphyxia." These symptoms are warnings to let well alone. Artificial respiration should be tried only at considerable intervals. The feeble circulation can not absorb much oxygen. An untimely compression of the thorax may abort a spontaneous gasp. Gentleness of manipulation and patience are supremely necessary. The attendant should have the nerve to wait long minutes between gasps if the pulse holds its gain in rapidity and strength. But it is well to lift the child from the bath at regular intervals, and hold it head down while a movement of artificial respiration is practised.

In a case which seems to become a failure any rational means is justifiable, alcohol, strychnine, or atropine under the skin or a teacupful of hot sal solution passed into the rectum may be tried. But in my observation when failure came it came so rapidly that there was no time for these to do their

work.

When the patient has reached the point of gasping spontaneously at fairly regular intervals, and the skin is blue and the musculature again has tone, a quick dip into cold water will usually establish respiration with a spectacular convulsive gasp, and a more or less vigorous yell. But in my last case of this kind it was more than half an hour after birth before I dared to try it.

A child which has been so near death should be guarded in the after treatment from the curiosity and officiousness of relatives and friends by the best available nurse, and the most complete rest possible

to obtain.

When still a student, a fortunate opportunity to observe the patience and gentleness of Dr. C. M. Green in a case of this kind at the Boston Lying in Hospital, taught me this method. A fortunate opportunity to practise it soon afterward, as assistant to an older physician, confirmed me, and I have never used any other. I have not saved every child, but I have felt satisfied that I had done the best possible thing even when I have failed to preserve life.

Dr. Richard A. Bolt, of Cleveland, Ohio, remarks:

Intelligent and judicious treatment of asphyxia neonatorum requires some knowledge of the mechanism of respiration. Briefly, the fœtus in utero may be considered in a state of apnœa, deriving its oxygen through the placental circulation by means of osmosis and diffusion from the oxygenated maternal blood. Asphyxia results from a deficiency of oxygen in the fœtal circulation, or subsequently in the newborn, leading to accumulation of carbon dioxide in the blood with its toxic effects upon the respiratory nervous mechanism. Treatment of asphyxia neonatorum, therefore, resolves itself into prevention of any condition which shuts off, in part or whole, the oxygen supply from the fœtus in utero or in its passage through the birth canal, or mechanically hinders initial respiratory movements in the child when born. It also implies that there should be no interference with the initial reflexes which promote respiration. A knowledge of practical methods of resuscitation is most essential for successful treatment.

Prophylaxis is largely in the hands of the obstetrician, who may forsee many ante partum causes of asphyxia. Careful measurements of the pelvis, and an estimation of the relative size of the child may give valuable information as to when interference is demanded. If labor proves too long or severe it should be terminated as rapidly as is consistent with the welfare of mother and child. Indications for forceps should constantly be kept in mind, and applied when deemed necessary. When applied, the forceps should never be pressed too firmly upon the head for any length of time. Intermittent gradual pulling is preferred to a long continuous extraction. It should be remembered that while a prolonged second stage predisposes to a terminal asphyxia in the child, a careless or unskilled application of forceps leads to the same result. If a breech extraction or version is necessary care should be exercised to deliver the head within eight minutes after the umbilicus appears. When a prolapsed cord complicates the case every possible effort should be made to replace it, and retain in a high position until the presenting part engages. The knee chest position should be assumed, and the cord replaced with some suitable device. If one or more coils of cord are around the neck, gentle effort should be made to slip them back over the shoulders and body; this failing, a couple of clamps may be applied and the cord cut between them.

Intrauterine signs of asphyxia should be carefully The fœtal heart should be auscultated from time to time during labor. A progressive increase in rapidity reaching 180 to 190 per minute must be regarded as a sign of danger. If this is followed by a marked slowing, approaching 100 per minute, it is as a rule an indication for rapid delivery if the child's life is to be saved. Premature separation of the placenta, as indicated by an undue amount of blood in the early stages of labor and changes in the fœtal heart, must be looked for, and operative interference instituted as soon as possible. The mother should not be given an excess of any anæsthetic, or maximal doses of any depressing drugs, such as chloral and morphine. The use of ergot in the second stage is injudicious. Should the

death of the mother be imminent, the child may be saved by a very prompt delivery or Cæsarean section.

As soon as the head is delivered the face should be gently wiped off with sterile gauze, and the little finger covered with gauze inserted into the mouth and swept over the pharynx to remove as much of the mucous, amniotic fluid, and blood as possible. This simple procedure will often cause the child to take the first inspiration. Unless there are distinct indications for haste, the body should not be extracted with too much celerity. As a rule, late ligation of the cord should be practised.

When the body is born the child should be firmly grasped by the feet with a towel, and suspended with head downward, thus favoring gravitation of liquor amni and mucus from the bronchi, as well as affording an extra blood supply to the head. The back of the child should then be sharply slapped, beginning at the buttocks, and gradually going down to the shoulders. At the same time the physician may direct several breaths of air against the child's chest. or spray upon it alcohol and ether. As tenacious fluid collects in the pharynx, it must be gently wiped out. Most normal infants will respond with an inspiratory effort to this treatment, and a vigorous cry eventuate. If the asphyxia is more profound, and there is excess of mucus in the bronchi, a small tracheal catheter may be introduced and suction exerted with a bulb or syringe. Artificial respiration may then be consistently begun. Combined with this, the child should be placed alternately in hot (110° F.) and cold (iced or tap) water, being held with one hand under the shoulders, the thumb and index finger supporting the head, and the other hand under the thighs. As the child is transferred from one water to the other, its thighs and abdomen should be compressed against the thorax, and then gradually released and bent backward. The first movement should always be one which favors expiration. The doubling of the child upon itself may be repeated ten to twelve times per minute. This Byrd Dewey method if conscientiously pursued is one of the most useful at our command, with minimum amount of danger to the child.

It here becomes necessary to distinguish between two clinical forms of asphyxia, as treatment differs somewhat. In livid asphyxia the child is deeply cyanosed, reddish blue; the muscles retain some tone; the sphincters are still active, and the reflexes present to some degree; the heart beat is perceptible and usually rapid. In pallid asphyxia the color of the child is a cadaveric hue; the facies appears as in death; there is little if any resistance in the muscles; the sphincters are relaxed; the pupils dilated; the reflexes cannot be excited, and the heart beat is very

feeble, scarcely perceptible.

In livid, or blue, asphyxia chief reliance must be placed in exciting the reflexes. Slapping, hot and cold water, and Byrd Dewey method should first be given a trial. If these do not succeed, a consistent and prolonged course of artificial respiration should be begun. Efforts to save the child should not be given up until it is quite certain the heart has ceased to beat. The Sylvester method of artificial respiration has been used by many with fairly good results. This consists in placing the child on its back upon a firm surface, with its shoulders slightly elevated and

head hanging lower. The arms are then compressed firmly against the chest and abdomen to favor expiration, and then raised slowly above the head to cause inspiration. These movements are alternately kept up twelve to fourteen times a minute. method of Schultze of supporting the child under the shoulders and swinging it from between thighs of the physician up over the head is too violent to receive unqualified approval. I have found the other methods much more satisfactory, and equally efficient if rightly pursued. In severe cases of asphyxia, rhythmical tractions upon the tongue, as described by Laborde, should be tried. The tongue is gently pulled out to its limit, and then relaxed about fourteen times per minute. This sometimes stimulates respiration when other methods seem powerless. When respirations have begun the child should be warmly wrapped in a blanket, but not tightly about the chest and abdomen, and by no means covering over the face. It should be placed with head moderately low, and carefully observed to see that respirations continue.

In pallid asphyxia the problem is to get oxygen into the circulation as soon as possible, and at the same time keep up respiration. The child must be kept warm, and no rough handling permitted. Immersion in a hot water, or mustard, bath is desirable while treatment is carried out. Mucus and amniotic fluid should be removed from the bronchi as described before. Then air may be directed into the child's lungs by either mouth to mouth insufflation, or by means of a tracheal catheter and bulb. The air should be gently blown in, and gradually withdrawn. At the same time some of the milder methods of artificial respiration should be begun. If a tank of oxygen is at hand it may be administered, fairly well diluted with air. When respiratory movements are excited they should be kept up for some little time by artificial means, and the child closely watched. In my experience the subcutaneous injection of strychnine and other stimulants in asphyxiated infants has proved of little or no value.

(To be continued.)

Therapeutical Hotes.

Veratrum Viride in Puerperal Eclampsia .-The convulsions in puerperal eclampsia constitute the most striking manifestation of this disease, of which the exact nature and origin are still unknown. Moreover, the convulsive fit is itself a source of great danger to the patient, especially when frequently recurring, after brief intervals, and producing important circulatory disturbances. Thus the increased blood pressure, produced by the convulsion, acting upon bloodvessels, already altered by the colamptic poison, may cause their rupture, and so lead to cerebral hæmorrhage. Again, pulmonary and aspiration pneumonia not uncommonly result from the convulsions, and are among the common causes of death in eclampsia. In these circumstances, any drug, which will control this most dangerous symptom of eclampsia, is likely to have a good effect on the disease itself. This result has been secured by the hypodermic administration of the fluidextract of veratrum viride in small

and repeated doses. The character of the pulse must be taken as the guide in its administration. Where the pulse is full and strong, above 80 beats a minute, veratrum should be administered. On the other hand, where the pulse is rapid and small, and the arternal pressure is but slightly elevated, veratrum viride is contraindicated. A recent Italian writer has treated one hundred cases of eclampsia in the last ten years in this manner, with a maternal mortality of twelve per cent., and a feetal-mortality of 43.37 per cent. whereas, in the preceding ten years, before the introduction of the use of veratrum viride, he had a maternal mortality of 23.68 per cent.—The Practitioner, December, 1908.

Tonic Treatment of Constipation. Estmonnet (Journal de médecine de Paris, November 28, 1908.) prescribes a pill of the following composition, one of which is directed to be taken after each meal.

| \mathbb{R} | Pulverized | | | | | | | |
|--------------|-------------|---------|------|--|--|--|------|------|
| | Pulverized | ergot. | | | | | .gr. | 111; |
| | Extract of | bellado | nna. | | | | gr. | 1/7. |
| M. | Fac. pil. N | o. XX. | | | | | | |

The Treatment of Migraine.—According to Pron (Journal de médecine de Paris, October 10, 1908) migraine is almost always due to a condition of dyspeptic hyperchlorhydria, and the treatment of this condition may be employed against the diathesis. In addition to an antidyspeptic diet the constipation is treated by free purgations. The essential thing is to modify the secretion and functions of the stomach by the daily ingestion of alkali earths according to the following formula:

Calcium phosphate;
Prepared chalk;
Magnesium carbonate;
Sugar of milk.

M. et Sig.: One teaspoonful of the powder to be taken after the two principal meals in a cupful of warm water.

The addition of the sugar of milk and the magnesia is deemed useful to overcome the constipating action of the calcium phosphate and chalk, while the magnesia acts as an antacid.

At the onset of an attack of migraine the symptoms may be greatly ameliorated by the administration in a cupful of hot water of the following powder:

| Prepared chalk; |
|-----------------------------------|
| Magnesium carbonate; |
| Calcium phosphate, |
| Bismuth subnitrate,gr. viiss |
| Pulverized opium,gr. 1/3 |
| Sparteine sulphate,gr. 3/5 |
| Pulverized belladonna leafgr. 1/3 |

The same dose should be administered several hours later if needed. The application of hot compresses to the abdomen is prescribed at the same time.

The Use of Tincture of Iodine in Eczema.—The application of tincture of iodine to an eczematous surface proved satisfactory in the hands of J. H. E. Tomlinson (*The British Medical Journal*, October 17, 1708) after several remedies had been tried unavailingly. The case was one of relapsing moist eczema. Under the influence of the tincture painted lightly on the eczematous patch four times daily the itching ceased, the vesicles dried up, and the skin peeled off, leaving a healthy surface.

NEW YORK, SATURDAY, DECEMBER 26, 1908.

UNDRAWN POULTRY IN COLD STORAGE.

Attention has repeatedly been called to the practice of keeping undrawn poultry for long periods in cold storage. The practice is certainly disgusting and probably inimical to the health of the community. Some time ago the subject was studied by the United States Department of Agriculture, and it was found that the time that such fowls were kept in storage was occasionally as long as four years. The general opinion in the trade seemed to be that undrawn poultry, kept properly frozen, would be preserved for a long time without detriment. The investigations made by the government laboratory, however, showed that this was not the case. Both microscopical study and the taste of the cooked fowls showed that gross visible degeneration did take place.

Although no bacteriological examinations appear to have been made, some light is shed on the nature of these changes by the investigations recently reported by Pennington, in the Journal of Biological Chemistry. She studied the extent of bacterial growth in milk kept at low temperatures, and found that this was far more extensive than was usually believed. Thus, in clean milk kept at less than o° C., and containing originally 300 germs to the cubic centimetre, the number of germs at the end of five or six weeks was several hundred millions. The casein of the milk was reduced to about half its original amount. The taste and odor of the milk were not changed by this bacterial development, and

the milk did not coagulate on being heated. At low temperatures the liquefying organisms developed more than the acid producers, but at higher temperatures the reverse was the case.

Considering the importance of the subject, it is strange that so little work has been done on the bacteriology of undrawn poultry kept in cold storage. In view of the findings of the Department of Agriculture, it would appear to be advisable to establish a maximum time limit beyond which such poultry could not be kept. In order to fix such a limit, however, we must be in possession of far more scientific data than we now have.

LEPROSY IN THE UNITED STATES.

In the Evening Post of November 3d there is published a vigorous statement by Dr. Albert S. Ashmead, formerly foreign medical director of the Tokyo Hospital, of the need in this country of at least one institution for the care of lepers, and an appeal is made to private philanthropy for funds for this worthy purpose. Both common humanity and an enlightened self interest demand a more generous and humane provision for these incurable sufferers, a class of unfortunate patients in the care of whom we have been singularly backward. There is good reason to believe that there exists in the United States a larger leper population than is generally admitted. In the States of Louisiana, Minnesota, North Dakota, South Dakota, Wisconsin, and California, and in the Aleutian Islands of Alaska, leprosy may be fairly said to be endemic, and with increasing frequency sporadic cases are being reported from all our large cities. The ignorant and unfeeling manner in which these cases, when made known, are generally dealt with by our municipal authorities is a disgrace to a civilized

There has probably been an actual increase in the number of such cases since the termination of the war with Spain, with its resulting territorial expansion and the closer relations we have acquired with Cuba, the Philippines, the Hawaiian Islands, China, and Japan. Our leper population doubtless exceeds that of Norway, and vet that small and relatively poor but highly enlightened country provides three hospitals, two at Bergen and one at Trondhjem, for its lepers, who through a policy of intelligent segregation have been reduced in number from 2,870 in 1856 to fewer than 500 at the present time. It is estimated that there are fully 400 cases of leprosy among our population of Scandinavian immigrants alone, and this estimate is probably not excessive, as it about corresponds to the present incidence of the disease in Norway,

from which, it should be remembered, the United States has received immigration in recent years nearly equal to the present total population of Norway.

THE AGGLUTINATION TEST IN TUBERCULOSIS.

With the recent visit of Professor Courmont to some of the local laboratories interest has again revived in the agglutination test in tuberculosis, first described by Arloing and Courmont in 1898. Those who have followed the laboratory work in tuberculosis will recall that the important feature of the technique in the test consists in the preparation of a homogeneous culture of the tubercle bacilli. The homogeneous culture first prepared by Arloing and Courmont was grown on a potato and then transplanted into glycerin bouillon. The latter culture was then shaken briskly several times a day while in the incubator. In this way the tubercle bacilli were gradually made to grow all through the bouillon instead of merely in a crust on the surface. The cultures which Professor Courmont demonstrated while on his visit to the recent Tuberculosis Congress are uniformly cloudy like a typhoid culture.

The test is performed like ordinary agglutination tests, but macroscopically. In a set of three small test tubes are placed, say ten, ten, and fifteen drops of diluted culture respectively, and to these are added two, one, and one drop of serum from the suspected individual respectively. This gives dilutions of one to five, one to ten, and one to fifteen. Depending entirely on the agglutinability of the culture, the agglutinations resulting in these dilutions are to be interpreted. With a culture of ordinary agglutinability, a positive reaction in the one in five and one in ten dilutions, in an individual already suspected on clinical grounds of being tuberculous, is indicative that such infection is present. On the other hand, if in an individual known to be tuberculous there is no agglutination in these dilutions. this is taken as an indication of low resistance, of a failure to produce antibodies, and therefore as a sign of bad prognosis.

While it is true that a number of unfavorable comments have been made on this reaction, not only by the workers in this country, but also and especially by the German workers, it would seem desirable to have the test thoroughly tried. Certainly every diagnostic and prognostic test that is really of value should be available for those engaged in the study and suppression of this disease. Furthermore, there are few departments of immunity about which we are so ignorant as that concerning the antibodies in tuberculosis. We commend this test to the attention of our laboratory workers.

A SUPPOSED PATHOGENIC ACTION OF RADIOACTIVE WATERS.

Before the French Academy of Sciences (Presse médicale, November 4th) M. Répin remarked lately that he had observed that the Alpine spring waters that were supposed to give rise to goitre were constantly characterized by a notable radioactivity, and that it was attributable, at least in great part, to radiothorium. This condition, analogous to what was constantly found in waters more or less mineralized, led him to ask if radioactivity was not an attribute common to all waters proceeding from a great depth after prolonged contact with volcanic rock containing scattered traces of radium and If this was really the case, and if this radioactivity, as M. Répin supposed, counted for something as a cause of endemic goitre, it could be quite explained why the disease in all parts of the world prevailed most particularly in mountainous and upheaved countries, while it showed itself only sporadically in plains of stable stratification and stopped short at the boundary of homogeneous crystalline belts. On such a supposition, he said, we might explain the success recently met with by a number of English physicians in the treatment of goître by restricting the patients to the exclusive use of distilled water.

THE TITRATION OF DIPHTHERIA ANTITOXINE.

Except to those directly engaged in immunity studies it will probably be news that there is still some difference of opinion concerning the mode of titrating diphtheria antitoxic serum. We have so long been accustomed to hear the strength of this serum expressed in terms of Ehrlich's units that we naturally associate the therapeutic power with the antitoxine units present in the serum. Some years ago Roux advanced the proposition that there was no parallelism between the curative and preventive value of diphtheritic antiserum and the number of its antitoxine units. In support of this view he brought forward the results of experiments made by Momont and Danysz, which showed that a serum which contained three and a half times as many antitoxic units (by Ehrlich's method) as another serum was really inferior to the latter in both preventive and curative properties.

Since the publication of these experiments, the subject has been studied by other investigators, among whom may be mentioned Marx, Madsen, Dean, Cruveilhier, Kraus, and Steinhardt and Banzhaf. Of these, only Cruveilhier and Kraus arrived at results confirming Roux's statement. So far as the work of Kraus is concerned, it subsequently appeared that the antitoxic strength of the

sera used had not been fixed with sufficient accuracy to warrant the conclusions drawn. Cruveilhier's experiments were repeated step for step by Banzhaf. of New York, but with entirely different results. The therapeutic value of the serum was always parallel with the antitoxic strength as measured by Ehrlich's method. In connection with this subject it is interesting to note that a Viennese clinician believes he has found that a low grade diphtheria antitoxine gives better clinical results than a high grade serum used at the same time. In view of the extended use of diphtheria antitoxine, it would be very strange if this was really the case. The weight of evidence is certainly strongly in favor of the current view, namely, that the therapeutic power of the serum is measured by the number of its antitoxic units. Perhaps some of our clinicians can contribute something to this interesting discussion.

CATAPHORESIS IN THE TREATMENT OF CYSTITIS.

At a recent meeting of the French Association of Urology (*Presse médicale*, November 4th), Dr. Denis Courtade reported his experience (but, so far as the report goes, not his results) in five cases. The remedy employed was a five per cent. solution of sodium salicylate, a current of five milliampères being passed for ten minutes at a time three times a week.

PREGNANCY AFTER DOUBLE RENAL DECAPSULATION.

A case reported by Dr. Chambreland, of Bordeaux, at a recent meeting of the Obstetrical Society of France (Presse médicale, November 4th) seems to have some bearing upon two points connected with the relief afforded by decapsulation in renal disease—that of the promptness of its action and that of its duration. A woman was in a persistent state of coma after several eclamptic paroxysms. Labor having been terminated and scantiness of urine continuing, the kidneys were decapsulated. The convulsions ceased immediately, and then the coma disappeared. Her general health was rapidly ameliorated to the point of complete reestablishment. Two years later she became pregnant again, and the pregnancy pursued a normal course, and was followed by natural labor and a favorable lving-in period.

"COALS TO NEWCASTLE."

At the top of one of the columns of its first page, the *New York Times* of December 19th published a London "special cable" introduced by the following headlines: "Find Use for Appendix. Abused Or-

gan Employed as Tube to Convey Medicine to Lower Intestine." "The vermiform appendix," says the dispatch, "which has been looked upon hitherto as a useless and even dangerous organ, has at last justified its existence, according to a statement made by the surgeon of a London hospital, where the appendix has been shown to be a great help in treating diseases of the lower intestine." It then goes on to a crude description of the use to which the appendix has been put in irrigating the large intestine through "its lumen passage."

All this, which occupies about six inches of the newspaper's column, has reference of course to the operation known as appendicostomy, which was described more than five years ago (in the *Medical Record* for August 9, 1903) by Dr. Robert F. Weir, of New York. Since that time, as we learn from an excellent article contributed by Dr. W. B. Russ, of San Antonio, to the *Texas State Journal of Medicine* for July, 1908, several American surgeons have written on the subject in various journals. To telegraph such "news" to New York seems to us, therefore, very much like "carrying coals to Newcastle."

THE ARCHIVES OF DIAGNOSIS.

The October number of this quarterly, closing the first volume, warrants a continuance of the favorable opinion which we expressed of an early number. It contains articles by such well known men as Dr. Godfrey R. Pisek, Dr. Alfred C. Crofton, Dr. Thomas F. Reilly, Dr. Charles Greene Cumston, Dr. Byron Robinson, Dr. Carl Beck, Dr. Robert T. Edes, Dr. Alfred Gordon, Dr. S. D. Ingham, Dr. Tom A. Williams, and Dr. Ralph Waldo, as well as by the accomplished editor, Dr. Heinrich Stern.

THE ANTIVIVISECTION AGITATION.

The secretary of the Committee on Legislation of the Medical Society of the State of New York reminds the profession of the State that the antivivisectionists are bent on renewing their efforts to secure restrictive legislation that will seriously hamper the progress of medicine in so far as it is based on animal experiments. He points out that in their propaganda they are making use of appeals founded largely on assumptions and unsupported allegations. The Medical Society of the State of New York, he informs us, is prepared to furnish literature setting forth the truth with regard to experiments on animals, and to provide speakers for clubs and societies that are interested in the subject. Such speakers can undoubtedly accomplish a great deal in the way of enlightening the public concerning the care taken by experimenters to avoid cruelty and concerning the adequacy of our present laws for all legitimate purposes.

Rems Atems.

Executive Secretary for the Tuberculosis Exhibit .-The Executive Committee of the International Exhibition in Philadelphia has selected Dr. F. N. Yeager as executive secretar

The Medical Society of the Borough of The Bronx held a clinical meeting on Wednesday, December 9th. programme consisted of the presentation of patients and the reports of cases, followed by a general discussion.

The Medical Jurisprudence Society of Philadelphia.-At a stated meeting of this society, which was held ou Monday evening, December 21st, Dr. Alfred Gordon delivered an address on Amnesia from a Medicolegal Stand-

Dr. Rotch on Child Labor .- Dr. Thomas M Rotch, of Boston, the distinguished pædiatrist, delivered an address on Child Labor to the physicians of Philadelphia, at the Jefferson Hospital Amphitheatre, on Monday, Decemher arst

Scientific Society Meetings in Philadelphia for the

Week Ending January 2, 1909:

MDAY, December 18th.—Mineralogical and Geological Monday, December 18th.—Mineralogical and Geolog Section, Academy of Natural Sciences. Friday, January 1st.—American Philosophical Society.

The West Philadelphia Medical Association.-The following officers have been elected to serve for the ensuing year: President, Dr. F. M. Cleveland; vice-president, Dr. S. F. Gilpin; secretary, Dr. George Mills Boyd; financial secretary, Dr. W. M. Miller; treasurer, Dr. E. L. Graf.

The Buffalo Academy of Medicine.-A stated meeting of the academy was held on December 22d, under the auspices of the Section in Pathology. The principal feature of the programme was a paper on Absorption from the Peritoneal Cavity, by Dr. W. G. MacCallum, of Baltimore.

The Medical Society of the County of Richmond, N. Y., elected the following officers at a recent meeting: Dr. Eugene J. Callanan, president; Dr. Walker Washington, vice-president; secretary and treasurer, Dr. Charles E. Pearson; censors, Dr. George Jessup, Dr. W. J. Bryan, and Dr. E. E. Hillyer.

The Red Cross Christmas Stamps .- Announcement is made by the chairman of the Christmas Stamp Committee of the New York County Subdivision of the National Red Cross that by the end of the month more than five millions of the stamps will have been sold in New York. Similar reports are being received from every large city in the United States, as well as the smaller cities and towns.

The Syracuse, N. Y., Academy of Medicine.-A meeting of this academy was held on Tuesday evening, December 22d, in the Carnegie Library Building. Dr. H. B. Doust presented a report of the work of the tuberculosis clinic for the past eight months. Dr. J. R. Wiseman read a paper on Perforated Duodenal Ulcer. The Library Committee submitted its report, and officers for 1909 were

Contagious Diseases in Chicago .- During the week ending December 12, 1908, there were reported to the Department of Health 867 cases of contagious diseases, as follows: Diphtheria, 222 cases; scarlet fever, 213 cases; measles, 98 cases; chickenpox, 132 cases; pneumonia, 26 cases; typhoid fever, 47 cases; whooping cough, 21 cases; tuberculosis, 82 cases; other diseases of minor importance, 26 cases.

Philadelphia Academy of the Natural Sciences.--At the annual meeting of the academy, which has held on the evening of December 15th, Dr. Samuel G. Dixon, State commissioner of health, was elected president for the fourteenth consecutive time. The two vice-presidents, Arthur Erwin Brown, Sc. D., and Edwin G. Conklin, Ph. D., were reelected, as were also the secretaries, the treasurer, and the librarian.

The Manhattan Medical Society held a stated meeting on Friday, December 18th. After the presentation of patients and the exhibition of specimens, surgical instruments, etc., two papers were read, one by Dr. H. Edwin Lewis on Malignant Disease of the Lung, with Report of a Case of Sarcoma, and the other on Latent Malignant Disease of the Stomach, by Dr. Heinrich Stern. A clinical conference on expectorants was held, and a general discussion followed.

New Buildings for Beth Israel Hospital.-The present buildings of this institution, which is situated on Cherry Street, are wholly inadequate to meet requirements, and plans are being prepared for the erection of new buildings The building committee has been instructed to select a site on the east side, somewhere between Houston and Twenty-third Streets. In addition to the real estate holdings of the hospital association the building fund amounts to \$100,000, and many liberal subscriptions have been promised.

Consumptives as Trained Nurses.—Dr. George B. Wight, Commissioner of Charities and Correction of New

Jersey, is quoted as recommending that the New Jersey Tuberculosis Sanatorium at Glen Gardner be used as a training school for tuberculous patients instead of a sana-torium merely. This sanatorium receives only incipient cases, and Dr. Wight believes that if these persons were properly taught they would become invaluable as trained nurses in local hospitals or camps, to care for others suffering with the disease.

Society Meetings for the Coming Week:
MONDAY, December 28th.—Medical Society of the County
of New York.

THURSDAY, December 31st .- Brooklyn Society for Neu-

rology.

Friday, January 1st.—New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynæcological Society, Brooklyn, N. Y.; Manhattan Cinical Society, New York; Practitioners' hattan Cinical Society of New York.

The Pacific Slope Public Health Association is the name of an organization recently formed in Portland, Ore at a meeting of representatives of the boards of health of practically every seaport town on the Pacific coast from Victoria, B. C., to San Diego, Cal. The object of the assoresolution is to secure protection against bubonic plague. A resolution was passed at the meeting that the legislative assemblies of the several States be asked to pass laws which would compel the fumigation of all vessels from off-shore

The Nobel Prizes.—The Nobel prize in medicine has this year been divided between Professor Elie Metchnikoft, assistant director of the Pasteur Institute, Paris, and Professor Paul Ehrlich, director of the Institute for Experi mental Therapeutics at Frankfort-on-Main. The Nobel prize in chemistry has been awarded to Professor E. Rutherford, F. R. S., director of the Physics Laboratory in the University of Manchester. The prize in physics has been awarded to Professor Gabriel Lippmann, professor of physics at the Sorbonne, Paris.

The Health of Pittsburgh .- During the week ending December 12, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Chickenpox, 20 cases, 0 deaths; typhoid fever, 17 cases, 7 deaths; scarlet fever, 23 cases, 0 deaths; diphtheria, 13 cases, 0 deaths; measles, 39 cases, 2 deaths; whooping cough, 9 cases, 1 death; pulmonary tuberculosis, 22 cases, 9 deaths. The total deaths for the week numbered 171, in an estimated population of 565,000, corresponding to an annual death rate of 15.73 in 1,000 population.

The Scientific Temperance Federation held its second annual meeting in Boston on December 8th. tary's report summarized the work accomplished by the organization during the past year, and presented briefly the outlook for the antialcohol movement from the scientific standpoint. The following officers were elected for the coming year: President, the Rev. C. A. Vincent; vice-president, Mrs. A. J. Gordon; recording secretary, Mrs. L. L. Transeau; corresponding secretary, Miss Cora Frances Stoddard; treasurer, Mr. Robert H. Magwood.

Changes in the Faculty of the Baltimore Medical College.—Dr. David Streett, dean of the Baltimore Medical College, announces certain changes in the faculty of that institution. Dr. Robert W. Johnson, professor of the principles and practice of medicine, who has been a member of the faculty for seventeen years, has resigned his chair and will retire from the faculty on January 1st; Dr. P. P. Wefold rescent of professor of anytony has been R. B. Warfield, associate professor of anatomy, has been elected to the vacant chair. Dr. William E. Moseley has resigned the chair of professor of diseases of women, which he has occupied for twelve years, and will retire on January 1st. He will be succeeded by Dr. W. B. Perry, associate professor of operative surgery.

The Medical Society of the County of Monroe, N. Y. -At the annual meeting of this society, acld on the even ing of December 15th, in Rochester, N. Y., the following officers were elected: President, Dr. T. A. O'Hare; viceofficers were elected: President, Dr. T. A. O'Hare; vice-president, Dr. C. E. Darrow; treasurer, Dr. R. R. Fitch, re-elected; secretary, Dr. C. R. Witherspoon, reelected. The following named physicians were elected to membership in the society: Dr. Christopher F. Chaffe, Dr. Charles W. Hennington, Dr. Edwin W. Kibbe, and Dr. Morris G. Or-chard, of Roehester, and Dr. F. H. White, of Fairport.

The East Side Physicians' Association, New York.-At a meeting of this association, which was held on December 18th, the programme included reports of the following cases; Uteri removed by Hysterectomy, by Dr. Abram Brothers; Extrophy of the Bladder, by Dr. George Dow Scott; Orthopædic Cases, by Dr. Sigmund Epstein. The paper of the evening was read by Dr. A. E. Isaacs, and was entitled Free Suppurative Peritonitis, Comment on Recent Discussions. Among those who participated in the discussion were Dr. A. G. Gerster, Dr. Howard Lilienthal, Dr Joseph Wiener, Dr. Henry M. Silver, and Dr. F. W. Gwyer.

The Memphis and Shelby County, Ky., Medical Society held its annual meeting in Memphis on December 15th. Dr. G. B. Thornton was elected president, to succeed Dr. Alexander Erskine. Dr. E. C. Blackburn was elected vice-president, and Dr. J. W. Price was reelected as secretary and treasurer. After the election of officers a banquet was held in the Hotel Cordova, Dr. B. F. Turner presiding as toostmater. presiding as toastmaster. Among those who responded to toasts were Dr. Alexander Erskine, the retiring president; Dr. George R. Livermore, the retiring vice-president; Dr. E. C. Blackburn, Dr. J. W. Price, Dr. William Krauss, Dr. Eugene Rosamond, and Dr. B. G. Henning.

The Hospital Saturday and Sunday Association of New York City announces that Saturday and Sunday, December 26th and 27th, will be Hospital Saturday and Sunday in New York. Contributions received on these days will be added to the general fund, and will be divided among the associated hospitals on the basis of free care for the sick. Contributions will be received through collections in the churches on Hospital Sunday, and in the synagogues on Hospital Saturday; through auxiliary associations in the trades; through the woman's auxiliary; through auxiliaries or committees on all the exchanges; or through gifts sent direct to Mr. Charles Lanier, general treasurer, 59 Cedar Street, New York.

A Dinner for Physicians .-- Mr. R. Fulton Cutting gave a dinner for Physicians.—Mr. R. Fulton Cutting gave a dinner on Sunday evening, December 20th, for the twen-ty-nine young physicians who worked during the summer in the depots of the New York Milk Committee in behalf of the babies in the congested districts. Eight nationalities were represented at the dinner—Jews, Italians, Germans, Bohemians, Hungarians, Irishmen, negroes, and Americans. Mr. Cutting is president of the New York Association for Improving the Condition of the Poor, under the direction of which the Milk Committee was organized, and the dinner was given as a tribute to the devotion and self sacrifice of the men who had given their time and energy to carrying on the work

The Medical Society of the County of Onondaga, N. Y., elected the following officers at the annual meet N. Y., elected the following officers at the annual meeting of the society, held in Syracuse, on December 15th: President, Dr. S. Ellis Crane; vice-president, Dr. T. H. Halsted; secretary, Dr. John C. Shoudy; treasurer; Dr. S. Allen Cone; censors, Dr. Frederick Flaherty, Dr. Arthur S. Ruland, Dr. A. E. Larkin, Dr. E. J. Wynkoop, and Dr. A. S. Hotaling; State delegates, Dr. John L. Heffron and Dr. D. M. Totman; delegates to Fifth district branch, Dr. George B. Broad and Dr. Dwight H. Murray. Dr. George H. Shaw, of Baldwinsville: Dr. George W. Stark, of Syracuse, and Dr. Horace G. Padgett, of Tully, were elected to membership. membership.

The Health of the Army in Different Sections of the United States is shown in the last annual report of the Surgeon General. From this it appears that the highest admission and noneffective rates and the lowest death rate occurred in the Department of the Gulf, while the lowest admission and noneffective rates were noted in the Department of California, and the highest death rate in the Department of the Columbia. The Department of the Lakes had the highest rate for typhoid fever, while the Department of Dakota had the lowest. The Department of Dakota had the highest rate for malaria and the Department of the Columbia the lowest. The Department of California had the lowest rate for pneumonia, while the Department of the Columbia had the highest; the latter department also had the highest rate for tuberculosis and the lowest for

The Jefferson County, Ky., Medical Association.—The handsome new headquarters of this organization in the Atherton Building, Fourth and Chestnut Streets, Louisville, were opened on the evening of December 14th with appropriate exercises. Dr. George W. Crile, of Cleveland, Ohio, who was the principal speaker of the evening, delivered an address on Acute Anæmia and its Treatment. Dr. B. F Zimmerman, the president of the society, presided, and Dr. Lewis S. McMurtry and other prominent physicians of Louisville delivered short dedicatory addresses, in which the history of the association was reviewed. The new headquarters contain an auditorium which will seat nearly three hundred people, and a library of three thousand volumes

Medical Society of the Woman's Hospital of Philadelphia.—A regular meeting of this society was held on Monday evening, December 21st. Dr. Clara T. Dercum exhibited a patient with an acute cerebellar lesion, and Dr. Matilda Osborne reported a case of pseudomuscular hyper-trophy. Papers were presented as follows: Treatment of Backward Displacements of the Uterus by the Alexander Operation, by Dr. Caroline M. Purnell; A Month in Bunm's Klinik, Berlin, by Dr. Catherine Macfarlane; Report of a Case of Cæsarean Section for Absolute Pelvic Contraction, by Dr. Mary W. Griscom; Report of a Case of Cæsarean Section for Disproportion between the Fætal and Maternal Parts, with Accidental Hæmorrhage, by Dr. Marie K. Formad.

The Investigation of New York's Oyster Supply. Announcement is made by the Health Department that, so far as their investigation of the oyster supply has been carried, everything indicates that the oyster beds are free from pol-lution, and that the method of storage prevents contamination. Dr. Walter Bensel, chief executive officer of the Department, after a personal investigation of the conditions under which oysters were grown off Cape Cod, in Great South Bay, Long Island, and in Lynnhaven Bay, Virginia, declared that there was not the slightest danger of the contamination of these oysters with typhoid germs. It is reported that on January 15, 1909, a general conference will be held in New York of the Commissioners of Shell Fisheries from sixteen States, the object being to advance the industry in the several States through taking care of the

Infectious Disease in New York:

We are indebted to the Bureau of Records of the De-partment of Health for the following statistics of new cases and deaths reported for the two weeks ending Decomber 10. 100

Charitable Bequests .- The German Hospital, Brook-

lyn, has received \$10,000 from the William Ulmer estate, and \$10,000 from the Charles Pfizer estate.

By the will of William H. Potter, of Kingston, R. I., the Butler and Rhode Island Hospitals, Providence, receive \$10,000 each; also lands in Providence and Cranston, and one-fourth of the remaining stocks and bonds not otherwise

By the will of the late Frederick Persch, of Buffalo, the German Hospital, Buffalo, receives \$1,000, and the Ger-

man Deaconness Home and Hospital receives \$2,000.

By the will of Dr. William Mackie, who died recently in Milwaukee, the Milwaukee Hospital receives \$2,000, and Dr. Mackie's medical library, composed of several hundred

By the will of Sarah R. Kolb, the Philadelphia Home for Incurables and the German Hospital, Philadelphia, receive \$5,000 each for the endowment of free beds, the German Protestant Home for the Aged receives \$1,000.

Dith of Current Titerature.

BOSTON MEDICAL AND SURGICAL JOURNAL

I. Some of the Difficulties, Professional and Social, of the Early Recognition of Tuberculosis, and Some Suggestions as to the Remedy, By EDWARD O. OTIS. Medical Inspection of Schools from the Standpoint of

the Medical Inspector,
By John T. Sullivan, T. J. Murphy, and M. J. Cronin.

Observations on Epilepsy (To be continued), By EVERETT FLOOD.

Shall the Tuberculosis Patient Be Treated in the Home Climate or Sent to Some Region with a More Equitable Climate, where More Hours Can Be Spent in the Open Air with Less Discomfort, By ISAAC WILLIAMS BREWER.

The New Silver Salts as Compared with Silver Nitrate in the Treatment of Ophthalmia of Newborn Chil-By HASKET DERBY.

Chronic Intestinal Catarrh (Concluded), By LESTER C. MILLER.

2. Medical Inspection of Schools.—Sullivan, Murphy, and Cronin observe that, although Boston is the pioneer city in the establishment of medical inspection of school children, there are many defects. Our authors are of the opinion that the system of medical inspection, including physicians and nurses, should be placed under the control of the Beard of Health. A chief medical inspector should be appointed, with deputies, if necessary, to have full authority over all, his function being to direct and control the work of the district inspectors and to see that each performs the duties required; also, through a supervising nurse, to direct the work of the nurses. The medical inspectors' powers should be definitely determined and specifically set forth, and a proper compensation should be given. The nurses should be subordinate to the district medical inspectors and should work only under their direction. A card system of records should be devised, to be filled out by both physicians and nurses, one set to be kept at the schools and another set at the office of the chief medical inspector. The Board of Health and the School Committee should cooperate in bringing about such needed reforms.

4. Shall the Tuberculous Patient Be Treated in the Home Climate or Sent to Some Region with a More Equitable Climate?—Brewer, while acknowledging the splendid results obtained in the Eastern sanatoria, believes that, all things being equal, better results can be obtained in the arid region than in the cloudy and humid atmosphere of the Atlantic States. He cites Dr. Osler, who, in discussing the subject of climate in the treatment of tuberculosis, says: "The requirements of a suitable climate are pure atmosphere, an equable temperature not subject to rapid variations, and a maximum amount of sunshine. Given these three factors, and it makes very little difference where the patient goes so long as he lives an outdoor life." There can be but little doubt, remarks our author, that the arid region of the southwest excels in purity of its atmosphere. There we find very few factories and other industrial establishments belching impurities into the air. Most of the impurities in our atmosphere are placed there by man or his instruments of labor. In Arizona the last census showed less than two persons to the square mile. The clearness of the

The Mortality of Chicago.-During the week ending December 12, 1908, there were reported to the Department of Health of the City of Chicago 537 deaths from all causes, as compared with 520 for the preceding week and 594 for the corresponding period in 1907. The annual death rate in a thousand population was 12.92, as against a death rate of 14.70 for the corresponding week in 1907. The total number of deaths of children under five years of age was 165, of which 104 were under one year of age. The principal causes of death were: Apoplexy, 7 deaths; Bright's disease, 30 deaths; bronchitis, 10 deaths; consumption, 53 deaths; cancer, 31 deaths; convulsions, 1 death; diphtheria, 23 deaths; heart diseases, 57 deaths; influenza, 4 deaths; intestinal diseases, acute, 33 deaths; measles, 5 deaths; nervous diseases, 15 deaths; pneumonia, 79 deaths; scarlet fever, 14 deaths; suicide, 10 deaths; typhoid fever, 2 deaths; violence (other than suicide), 28 deaths; all other causes, 135 deaths.

The Medical Society of the County of New York.—A stated meeting of this society will be held on Monday evening, December 28th, at 8:15 o'clock. Dr. James T. Gwathmey will exhibit an improved gas ether inhaler. Duncan Silkworth will read a paper entitled A Further Report on the Missionary Treatment of the Opium Habit, and will present patients. The remainder of the programme will consist of a "symposium" on Purulent Otitis Media. Dr. H. O. Reik, of Baltimore, will read a paper on the Pathology of Purulent Otitis Media, which will be illustrated with lantern slides. Dr. Edmund Prince Fowler will read a paper on the nonoperative treatment of this disease, accompanied by a demonstration of his method, and the erative treatment will be dealt with by Dr. Wendell Philips. Among those who will take part in the discussion are Dr. Edward B. Dench, Dr. Arthur B. Duel, Dr. James F. McKernon, Dr. Samuel J. Kopetzky, and Dr. Joseph A. Kenefick. At the close of the meeting a collation will be served, to which guests as well as members are invited.

The Health of Philadelphia.—During the week ending December 12, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 44 cases, 13 deaths; scarlet fever, 51 cases, 2 deaths; chickenpox, 93 cases, 1 death; diphtheria, 104 cases, 11 deaths; cerebrospinal meningitis, 2 cases, 1 death; measles, 45 cases, 0 deaths; whooping cough, 7 cases, 0 deaths; tuberculosis of the lungs, 100 cases, 14 deaths; cases, 0 deaths; tuberculosis of the lungs, 100 cases, 15 deaths; cases, 0 deaths; tuberculosis of the lungs, 100 cases, 15 deaths; cases, 0 deaths; tuberculosis of the lungs, 100 cases, 15 deaths; cases, 10 deaths; 10 10 dea cases, 53 deaths; pneumonia, 75 cases, 47 deaths; erysipelas, 5 cases, 1 death; puerperal fever, 2 cases, 0 deaths; cancer, 23 cases, 29 deaths; mumps, 9 cases, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than that of the lungs, 9 deaths; diarrhoca and enteritis, under two years of age, 21 deaths. The total deaths numbered 469 in an estimated population of total deaths numbered 409 in an estimated population, 15,32,738, corresponding to an annual death rate of 15,90 in 1,000 population. The total infant mortality was 98; under one year of age, 81; between one and two years of age, 17. There were 47 still births, 31 males and 16 females. The There were 47 still births, 31 males and 16 females. total precipitation was 2.01 inches.

Personal.-Dr. Joseph Tommasilli, an Austrian physician, who is connected with the Sanitary Bureau in the Panana Canal Zone, was recently bitten by a dog which showed signs of rabies. Dr. Tommasilli made a hurried trip to Washington, where he is now receiving the Pasteur treatment

Dr. William H. Wahl has resigned from the position of secretary of the Franklin Institute of Philadelphia.

Dr. E. P. Corson White, of Norristown, Pa., is registered

at the Philadelphia Polyclinic and College for Graduates in Medicine.

Mr. Charles F. Cox has been appointed the delegate of the New York Academy of Sciences to the Darwin centennial at the University of Cambridge.

Dr. Samuel G. Gant, professor of intestinal surgery at the New York Postgraduate School of Medicine, held a clinic at the Harper Hospital, Detroit, Mich., on Monday morning, December 14th, and in the evening of the same day he delivered an address before the Wayne County Med-

3. Sphenoid Operation.—Skillern describes the method of operation which he has found acceptable to all cases: The lateral wall of the nose, including the sæptum, is thoroughly cocainized with a 20 per cent. solution, a few drops of adrenalin chloride having been added. After anæsthesia has reached the point beyond tactile sensibility the posterior half of the middle turbinate is removed by means of the scissors and cold snare. After bleeding is controlled by lightly wiping with gauze soaked in adrenalin chloride the superior nasal passage with the superior turbinate is exposed to view. Hajek's ethmoid hook is now employed after the method of the author, and with two or three strong pulls the posterior ethmoid cells are broken through, the débris being removed with a Grünwald-Hartmann conchotome or a similar instrument. The sphenoidal sinus is now either exposed to view or opened completely up, depending on the anatomical construction of the part. Should there be present a sphenoethmoidal recess, the ethmoidal portion of the sphenoid wall will remain intact; if, on the other hand, the superior turbinate forms most of the anterior sphenoidal wall, breaking it down will naturally expose the sinus. We will suppose, however, that, after removing the

posterior ethmoidal cells, the anterior wall of the sphenoid has not been injured and we are able to see the ostium with pus oozing out. It is now an easy matter to introduce the evulsor, and with a few well directed pulls to open the ostium 8 to 10 mm. in diameter. The ostium is really never so small as it appears, because the mucous membrane, not only from the nasal side but from the interior of the sinus, joins to make more or less of a diaphragm. The bone at this point is paper thin, gradually becoming thicker toward the base and basilar process. The bent forceps of Hajek are now used and as much of the bone removed as is necessary to insure a permanent opening which should reach as deep as the floor of the sinus.

5. Circulatory Disturbances in Diphtheria.-Howland remarks that as far as treatment is concerned there can be no doubt that rest and general management accomplish much more than drugs. All are agreed as to this. On the subject of the value of the different circulatory stimulants there is far less unanimity of opinion. The number of drugs that have been advised in this condition is proof of their inefficiency, especially when practically all observers agree that digitalis, the most certain of all cardiac stimulants, fails in its effect. This at once raises the interesting question whether, if the cardiac muscle is so extensively diseased as to fail to meet the demands made on it by its normal regulatory apparatus it is capable of being advantageously stimulated by drugs. Clinical experience seems to indicate that it is not, and if occasionally a clinician speaks favorably of one drug it has always been found ineffective in the hands of others. Krehl frankly states that drugs are unsatisfactory. We can expect very little permanent effect from their use and permanency of effect is what is required, for the myocardial lesions require days and weeks and not hours for their cure.

10. Hydrophobia. — Dudley gives a concise résumé of the local treatment of hydrophobia. A tourniquet should be applied if the bite is on an extremity. The limb should be thoroughly scrubbed about the wound with green soap or other soap. The wounded part should be excised as in tetanus, if it can be done without injuring important structures or causing great mutilation. If the wound cannot be excised-only anatomical reasons, and not fears of scars, etc., should deter us from this measure-and is a punctured wound, it should be converted into an open wound by free incision. The wound should be scrubbed again with green soap or other soap and then with bichloride of mercury, I to 1,000. Pure carbolic acid and then fuming nitric acid should be applied. If these remedies are not at hand, other strong acid, and the actual cautery may be used, but nitric acid is preferable to the actual cautery. The wound should be left open and packed lightly with gauze moistened in bichloride of mercury I to 1,000 and wet dressing of bichloride of mercury I to 1,000 applied for twelve hours, and then dry aseptic dressing, which usually does not require to be molested until the wound is healed, unless the nature of the wound has required extensive excision, when it must require time to heal, by granulation, and may require several dressings. Cocaine may be used hypodermically, if necessary, for excision or incision of the wound, and may be applied to the wound surface before cauterization. The bite should never be sucked for fear that the one who sucks it may absorb the poison through an abrasion, and then, too, we must remember that the virus can be absorbed through the healthy mucous membranes. If Bier's cups are at hand, suction may be thus artificially applied before and after the wound is incised or excised. If the bite is on an extremity, the Bier hyperæmic treatment with the elastic bandage might also be tried. The preventive inoculation treatment of Pasteur should be administered as soon as possible. Since the commencement of the Pasteur preventive treatment about 55,000 persons have been inoculated. with an average mortality of 0.77 per cent. (Ravenel). In the New York Pasteur Institute, under the directorship of Paul Gibier, of 1,367 cases treated during the decade ending January 1, 1900, nineteen patients died, a mortality of 0.66 per cent. The patients should be sent to the Pasteur Institute at once, since delay tends to diminish the protective power of the treatment. It is, of course, useless after the malady is well developed.

11. A Comparison of Alcoholic and Watery Extracts in the Serum Diagnosis of Syphilis.— Marchildon observes that alcoholic extracts may be safely used in the reaction for the serum diognosis of syphillis, because they in no way differ from watery extracts. There are some nonsyphilitic blood sera which give a positive Wassermann reaction. These sera, however, are so rarely met, and then only in such extensive pathological processes, that they do not vitiate the clinical value of the reaction.

- The Prognosis and Treatment of the Deep Lesions of the Eye, Associated with Gout.-Ball remarks that the great danger in these cases of retinitis or chorioretinitis is the development of an acute glaucoma. The high blood pressure with its increased vascular tension tends at once to increase the intraocular tension beyond the normal limits and well within the danger zone. If this occurs in a hypermetropic or very astigmatic eye, with its shallow interior chamber, the almost inevitable result is a more or less complete obstruction of the

with its severe pain, paralysis of the sphincter iridis, engorgement of the deep episcleral vessels, cloudy cornea, and loss of vision. It should be fully recognized that an iridectomy should never be done in acute glaucoma, which has been preceded or accompanied by retinal or vitreous hemorrhages, and where the extensive cardiovascular disease makes general anæsthesia dangerous to the life of the patient. We have other means at our disposal for allaying the pain, reducing the tension, and arresting the inflammatory process, even if the eye remains permanently blind. The treatment and management of these cases must vary with the age and general condition of the patient, the nature of the lesion, and the severity of the type. The habits of life must be regulated, of course modified in strictness by the patient's condition and environment. It must be largely dietetic, based on accurate knowledge of the patient's digestive capabilities. The administration of drugs, except to combat certain symptoms as they arise, is of secondary importance. To reduce the high blood pressure, sodium nitrite as a vasodilator, may be used, but always combined with some reliable heart tonic. The local treatment of these deep seated ocular lesions is of great importance. An exudative retinitis or chorioretinitis, with or without hæmorrhages, occurring in patients of forty years of age or over, has a tendency to increase the intraocular tension, aside from the increased intravascular tension. As a result the subjective symptoms are impaired central vision, a sense of tension at times amounting to dull pain, and more or less intolerance of light. It is not safe to use atropine for the purpose of putting the accommodation at rest because of its tendency to increase the intraocular tension and aid in the development of glaucoma. Pilocarpine in a half per cent. or one per cent, solution should be used, as it contracts the pupil, draws the iris away from the angle of the anterior chamber, and lowers the intraocular tension. The light should be modified by wearing smoked glasses, but not darker than tint No. 3. In the uncomplicated acute glaucoma, unaccompanied by retinitis, chorioditis, or intraocular hæmorrhages, the classical operation of iridectomy should be done at once. This relieves the pain, lowers the intraocular tension, and in the great majority of cases ends the attack at once.

6. Notes on the Hospitals, Taken during a Visit to Scandinavia.—Boucher traveled through the three Scandinavian kingdoms, and describes his visit to the leading hospitals. Thus, he inspected the hospitals of the capitals, Christiania, Stockholm, and Copenhagen. He says that in all his travels abroad, he has never had the same amount of courtesy and attention shown him. They inquire about our American methods, and while they are not prompt in accepting all our newer ideas, they have a great deal of respect for American surgery and American surgeons. Dr. Behm, in charge of the Finsen Hospital, informed him that they had practically given up the use of x ray treatment in cancer, excepting a few superficial epitheliomata of the face, but in cancer of the lip, breast, and deep cancer, they advise immediate surgical operation, and then follow with the x ray treatment after the growth and glands

have been removed. He assured our author that not only in their work there, but from what he had seen in his travels in England, Germany, and France, he felt the x ray must be considered a failure in the treatment of cancer.

The Lymph Propulsion and Exchange.-Tack says that in studying the lymph propulsion it must be borne in mind that the lymph, unlike the blood, does not go rapidly coursing through the body through fixed and unobstructed channels with a high reserve pressure back of it. It, therefore, is more appropriate to use the word propulsion rather than circulation in studying or speaking of the forces that propel, and of the movements of the lymph. The lymph then, unlike the blood, goes slowly through the tissues of the body, on its mission of nutrition and body waste absorption, slowly finding its way, or being slowly propelled, from lymph space to lymph space, between tissue cells, or by chemotaxis, exosmosis, capillarity, diffusion, or dialysis, through thin animal membranes or connective tissue, as its chemical composition changes, as a result of stagnation or partial absorption to favor one or all of the laws of transudation, until finally it finds its way, through a slow but physiological propulsion, to the great lymph and blood centre of the body, or the lung tissue and lymphatics of the thoracic cavity. Just as sap works its way from the root of a tree to its leaves for oxygenation and vice versa, so does lymph work its way from the uttermost extremities of the body to the The forces that tend to keep up this normally procrastinating, sluggish, chemical change awaiting, lymph propulsion, are: 1, Absorption. 2. The muscular contraction or activities of the body and the pumplike action of moving articulations on the synovial cavity fluids. 3, The lymph aspirating action of the thoracic cavity upon the thoracic and other lymphatic ducts and vessels. 4, Last, but, although never before mentioned, not the least of the physical, chemical, and mechanical forces at work to perfect the propulsion of the lymph, is the anatomical and physiological fact that during respiration some lymph is aspirated into the mediastinum through the peritracheal, pericesophageal, and perivascular lymph spaces of the trachea, œsophagus, and the veins that enter the mediastinum, the chief of which are the inferior vena cava and the right and left innominate veins. The lymph thus conveyed to and aspirated into the mediastinum and other midpleural lymph spaces, also that reaching the same region through the lymphatics of the diaphragm, is absorbed by the pulmonary parenchyma or glandular lung tissue, through the open stoma or lymph mouths of the visceral pleura. Some of the lymph is aspirated into the lung tissue from the peritracheal lymph spaces along the peribronchial lymph spaces. The rest of the lymph reaches the lung tissue directly through the blood as that conveyed by the thoracic duct. In the lung the lymph is mixed with the blood and soon again through the glandular action of the lung tissue is separated or classified; some remaining in the blood, to be taken on by the blood current; some being absorbed by the lung lymphatics and conveyed to the mediastinal and bronchiotracheal glands; and finally some finding its way along the perivascular spaces of the pulmonary arteries, reaches or is aspirated into the pericardium, from which it is forced, together with the

lymph that reaches the pericardial space by absorption through the pericardium, with each heart beat along the perivascular lymph space of the aorta and its arterial branches, to feed or nourish the tissues of the body.

9. A Specific Skin Eruption in Pneumonia.

By F. M. POPE. 2. Early Diagnosis of Organic Nervous Disease.—Bradshaw gives his ideas as to the value of the principal signs on which we have to rely in making the diagnosis of organic disease of the nervous system in its early stages. Knee Jerk.-Entire absence of the knee jerk is always indicative of organic disease. It never happens in hysteria. In a patient who is able to walk about it generally means tabes dorsalis or neuritis. If the latter, it is most likely diabetic in origin. The real problem is to make sure of the absence of the knee jerk, not in the interpretation of it. Mere feebleness of response which is equal and constant is not pathological. Ankle Clonus and Exaggerated Knee Jerk .- Briskness of the knee jerks is apt to be looked on as an indication of organic disease, but as an isolated phenomenon it is rarely of serious moment. clonus, if sustained, always means organic disease, and may be the only positive indication of it. Absent Knee Jerk .- Absence of the knee jerk being never due to hysteria or other functional disease, must always be looked on with grave suspicion. Its importance as a sign of locomotor ataxia can hardly be overestimated. In the infrequent instances in which the brunt of the disease falls on the cervical cord, and the incoordination and other symptoms are chiefly in the upper extremities, the knee jerks may for a long time persist. But in cases where the complaint is of pains and other symptoms referred to the legs and lower part of the body, if the knee jerks can be obtained we can assure the patient that he has not locomotor ataxia. Ocular Signs.-Examination of the eyes may yield valuable indications of commencing organic disease, but it may also lead us into serious error. The presence of optic neuritis, apart from kidney disease, is strong evidence of a coarse intracranial lesion. But as a rule optic neuritis is more often falsely thought to exist than it is overlooked. To affirm its existence we must see distinct swelling of the disc, exudation, or hæmorrhage. Mere redness of the disc or tortuosity of the vessels must not be accepted as evidence of neuritis. Inequality of the pupils is apt

to give rise to a suspicion of general paralysis; but it may be normal to the individual; it occurs in neurasthenia and, rarely, in intrathoracic pressure. It may occur in uræmia. Diplopia, transitory or permanent, is suggestive of organic disease. A history of transitory diplopia is common in locomotor ataxia, and may confirm the diagnosis. But so called rheumatic neuritis of the sixth nerve may cause diplopia. Nystagmus, in the absence of ocular causes, is strongly suggestive of organic disease and may serve to indicate the existence of disseminated sclerosis when the other symptoms would seem to point to mere hysteria. Slight oscillations of the globe, especially on extreme voluntary deviation, may be merely due to fatigue or may be part of a general muscular tremor. The Argyll Robertson pupil is so common in locomotor ataxia and in general paralysis that it is seldom safe to make a diagnosis of either of these conditions, especially the former, in its absence, unless the other signs and symptoms are well marked. But undue weight must not be attached to its presence, even when accompanied by mental symptoms. Thoracic, Abdominal, and Pelvic Symptoms.—Bladder troubles are so common in the subjects of nervous disease that their occurrence ought hardly to give rise to errors of diagnosis. It is, however, possible to mistake for stricture or enlarged prostate, retention of urine due to loss of the vesical reflex. Unconscious nocturnal micturition may be the only indication of nocturnal epilepsy. Retention of urine is often due to hysteria; involuntary micturition never. symptom frequently met with in locomotor ataxia, both in the early and late stages, is persistent frequency of the pulse. The so called visceral crises of locomotor ataxia, of which the gastric crisis is the best known, may give rise to great difficulty and serious error in diagnosis. The characteristic of these gastric attacks is their sudden onset, their intense severity while they last, and the fact that the patient is usually quite free from gastric symptoms for longer or shorter periods between the attacks. The cases most likely to simulate them are those in which, owing to some adhesion or other mechanical abnormality, the pyloric end of the stomach, though perfectly patent as a rule, is liable to get twisted or kinked at times, so as to cause complete obstruction, followed by symptoms of acute dilatation of the stomach. Persistently recurring visceral disturbances, arising in a middle aged man without obvious cause, ought to give rise to a suspicion of locomotor ataxia, but unless some of the characteristic strict-Iv nervous signs are discovered on further examination, one is not justified in making a positive diag-

8. Enteritis Due to a Bacterial Rat Poison .-Handson, Williams, and Klein report an epidemic of enteritis, confined to twelve persons, all of whom took their meals in a room where the "Liverpool virus" was placed for the purpose of killing the rats with which the building was infested. The disease was of short duration, all the patients being convalescent in ten days. Vertigo was the initial symptom in all cases, followed by abdominal cramps, diarrhœa, and vomiting. Bacteriological investigation showed the microbe causing the disease to be identical with that of "Liverpool virus."

- hree Cases of Troping Leading By W. S. Sheppard, rically on the Extremities, By W. S. Sheppard, Note on the Ætiology of Beriberi and the Presence By C. V. Saldanha.

1. Inaugural Symptoms.—Moynihan draws attention to the urgent need which exists for a study of the very early symptoms of all diseases, but more especially of those affecting many of the abdominal organs. The surgeon about to operate has the opportunity to observe not only the parts he is immediately concerned with, but also all other viscera which can be laid bare through the same incision. If a morbid process in its earliest stage be then discovered, perhaps in parts other than those primarily concerned in the operation, the patient's story of his symptoms may be retold as soon as recovery is complete. It therefore rests with the surgeon to elicit the inaugural symptoms associated with the pathological changes which he finds within the abdomen, and by making sure of their significance and of the due order of their appearance, to furnish the knowledge that will ensure clinical recognition of visceral diseases in their early stages, in the stages when they are surely amenable to curative treatment. There are few catastrophes occurring within the abdomen that are veritably "acute." When we speak of such things we refer, as a rule, to the abrupt incursion of acute symptoms into the even and placid course of a disorder whose quieter manifestations have been present for months or years. In perforation of an ulcer, for example, the inaugural symptoms to be looked for are the sudden onset of an acute, intolerable pain that does not abate, rigidity of all the abdominal muscles, light and shallow breathing, with an inspiratory phase that usually ends abruptly in a "catch," together with the intensely anxious facial expression. These are ample warrant for a diagnosis of perforation. Rapid pulse rate, vomiting, and abdominal distension are late events, not inaugural symptoms, proving that time has already been wasted. In duodenal ulcer, again, hæmorrhage is a late event, yet it is often waited for before the diagnosis is made. Close attention to the inaugural symptoms of gallstones will repay us sevenfold. These inaugural symptoms are referred by the patients to the stomach, not to the liver or gallbladder. Complaint is made of epigastric distension and oppression, coming on soon after meals, relieved by belching, dismissed almost instantly by vomiting, elicited with remarkable constancy by certain articles of diet, and dependent rather upon the quality than on the quantity of the food. There is a sensation of great tightness, which if unrelieved may become acute pain, and which is relieved by bending the body forward, etc. There may be a feeling of faintness and nausea, and rarely there is vomiting. A frequent and very characterpicion.

istic early symptom of cholelithiasis is the occurrence during an attack of indigestion of a slight sensation of chilliness, especially in the evenings, after a meal. With the rarest exceptions stones do not develop in the gallbladder and do not remain there after their formation without exciting symp-These symptoms have not been adequately studied so far. Among the earliest evidences of the invasion of the colon by carcinoma are the following: First, the insidious onset of intestinal irregularity; now slight constipation, now slight diarrhœa. A second very significant early symptom is the occurrence of a spasm, slight and transient, in a part of the large intestine. The patient has a feeling of "gripping" and always in the same spot. This is clearly to be explained by the existence of a slight hypertrophy of the intestinal muscle as a result of the increased effort necessary to pass the contents of the gut through a segment in which stenosis is always beginning to appear. The occurence of mucus or of occult blood in the stools is probably to be expected in the comparatively early stages also. In appendicular inflammation, pain is in all instances the inaugural symptom; if other symptoms appear

first the diagnosis must be looked upon with sus-

5. Lactic Acid Baceria.—Allen tells us that in preparing curdled milk with any of the various lactic acid bacillary cultures, care should be taken that the milk is not previously contaminated bacteriologically. Should this be the case, the needful six to twelve hours incubation will enormously increase the contamination, thus rendering the milk very dangerous. To avoid this, the milk should be first sterilized by maintaining its temperature at boiling point for almost an hour, after which the lactic acid bacteria can be added. The writer cites two cases, illustrating the power of the lactic acid bacteria todrive out other organisms. One was a case of posttyphoid intestinal indigestion with numerous bacteria in the stools; here the lactic acid bacilli were given in the form of curdled milk. The other case was one of chronic gleet of years' standing, which had been treated with gonococcal vaccine. gonococci had disappeared but numerous other organisms persisted and kept up the discharge. Living cultures of lactic acid bacteria in milk were instilled into the urethra, with the result that the discharge ceased, and cultures showed nothing but the lactic acid bacteria.

9. Beriberi.—Saldanha states that beriberi is due to a substance he calls "arsin," which is the product of a fungoid disease of uncured rice. This substance is mostly contained in the rice dust. The poorer classes consume not only the rice, but the water in which it is cooked. In some cases the arsin causes diarrhœa and is eliminated; tolerance is soon established, and beriberi results. Beriberi is neither contagious not infectious any more than is arsenical or alcoholic paralysis. The neuritis in beriberi is quite secondary. The constant factor in the disease is vasomotor paralysis of terminal branches with tendency to chronic congestions of organs in which they ramify. Tea and stimulants seem to mask the effects of arsin, and when systematically withheld from a staple diet of uncured rice, an epidemic of beriberi is the usual result.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of April 8, 1908.

The President, Dr. Albert M. Eaton, in the Chair. LIFE INSURANCE AND MEDICAL PRACTITIONERS

The Various Forms of Life Insurance and their Comparative Value to the Physician.-Dr. CHARLES M. STELZER read a paper thus entitled. He said that in taking insurance one paid for what he got. No matter what representation was made as to the terms of the various forms of policy, the financial basis was fundamentally the same. Apart from the convenience offered, the value of all the various policies was the same. If the holder did not get at the maturity of his policy what he thought he would get, it was chiefly because he did not study the policy carefully at the time he took it out. Some years ago the policy usually was of the participating variety, that is, the insured shared in the profit and loss of the business, and as a result often did not get so much as was predicted by the agent. Lately, according to the law in some States, the companies had been obliged to give a guaranteed policy; they must give facts as to what a policy would be worth at the end of a term of years. This particularly applied to New York State.

The purposes for which insurance was taken out were protection of one's family and to meet business ventures, mortgages, etc. It was a moral obligation of the physician's to carry insurance, so that his family might be provided for in case of his death. It was also often the means of saving a personal estate by furnishing cash to pay immediate demands.

As to the form of insurance for the physician, for a man under forty-five years of age, the limited payment life policy, the payments, for example, to extend over twenty years, was the most desirable; above forty-five, unless one had large means and wished to pay for only ten or fifteen years, the best form was the ordinary life policy. The endowment policy cost more, but gave no more protection; it might, however, be regarded as a form of investment. It must be borne in mind that the old tontine, or deferred dividend, policies were very disappointing at maturity, because the predictions made at the time of their issue were based on the high rates of interest then prevailing as compared with more recent years. In New York such policies were now prohibited by law.

Two other forms of policy were, first, one which provided for the payment to the beneficiary of a certain sum annually after the death of the insured, and, second, one which paid to the insured a certain sum

annually during his lifetime.

"Substandard" insurance provided that one who was below par in health might take out a policy for a certain sum and pay a premium on that sum, but in case of death he was paid only a certain percentage of the face of the policy, this percentage increasing each year that the insured lived after taking out the policy, until, if he lived over thirteen years, there was received at death the face of the policy. In New York, since the recent legislation, this plan was no longer followed, but an extra premium was charged on these substandard risks.

Another important feature of recent insurance was the more liberal disability clause. This provided that during a period of total disability no premiums need be paid by the insured, but the policy still remained in force and lost none of its value.

The Bearing of the Recently Enacted New York Law on the Fee for Medical Examination of Insurance Applicants.-Mr. J. BURNETT GIBB, of the American Society of Actuaries, by invitation, read a paper thus entitled. He said that the New York law was the only one which affected the medical fee. The law provided that no company should expend in that State for commissions on first year's premiums, for other agency expenses, including advances to agents, and for medical examinations, an amount exceeding in the aggregate the total loadings upon the first year's premiums and the present values of the estimated mortality gains for the first five years of the insurance, as ascertained by the select and ultimate method. The cost of the medical fee cut deepest in the small policy and in the lower premium forms. For instance, on a ten year term policy issued at the age of twenty-one, for \$1,000, the annual premium was \$10.22, and, if a medical fee of \$5 was paid with an inspection fee of \$1, it would leave only \$4.22 to pay for carrying the risk one year, as well as the agent's commission and other expenses. This would be doing business at a

In considering what a proper fee was, the medical examiner should remember that the companies always met their obligations, so there were no bad debts in connection with these examinations. The protection of life insurance was not needed by any one more than by the man of small means, so the medical profession, by uniting in favor of a higher scale of compensation, must shoulder the responsibility of depriving the companies of the opportunity of extending the benefits of insurance to the class to whom it did the most good.

The Five Dollar Minimum Fee for Medical Examination of a Life Insurance Applicant.—Dr. I. NORMAN HENRY read this paper. He said the justification of the five dollar fee for medical examination seemed almost like a work of supererogation. There were two general classes of insurance, the industrial and the ordinary. The examination of applicants for the former was not nearly so exacting as for the latter, and the fee varied from twenty-five cents to three dollars. The larger companies issuing ordinary insurance usually had two classes of medical examiners, one spending regular hours at the office of the company and paid a salary, and the other composed of physicians in active practise who were paid so much for each examination. Gradually the companies had found that, in order to have good examiners, they must pay a reasonable fee; hence, many had fixed a minimum fee of five dollars. In several instances county medical societies had adopted resolutions demanding a fee of five dollars. This fee might have been obtained by less drastic action, smacking less of the methods of the labor union. The fee for professional work was purely arbitrary, and, as five dollars in the country was relatively larger than the same sum in the city, if this plan was followed the city physicians might feel justified in uniting on a seven or ten dollar fee. A fee of five dollars, no matter what the amount of the policy, would be most satisfactory to the physician, and in one instance at least it had proved so to the company. The examiner should not be influenced in any way by the size of the policy. Medical examination of an applicant required much skill and work and should be well paid for. The work of examining was best done by physicians in active practice, as they were best qualified to judge of the severity and consequence of abnormities encountered.

Honor Roll of Life Insurance Companies Paying the Five Dollar Minimum Fee for Medical Examinations.—Dr. ERNEST W. KELSEY read a list of companies that paid this minimum fee.

Dr. J. Allison Scott said he wished his remarks to be taken as from one in the general practice of medicine and not connected with any insurance He had, however, formerly been connected with an insurance company, and therefore had some knowledge of the business side of insurance which those working outside of the home office could not have. Often the medical director of a company might wish to do one thing, but the business officers desired to do the opposite, and often the latter prevailed. It was very common for an undesirable risk to be refused by the medical department and accepted by the president and vice-president. The reverse was also true. This might be due to some outside information which the business officers had received about the habits or history or occupation of the applicant. He doubted very much if the medical officers wished to keep the examiners' fee down, but believed they were overruled by the business officers. It would be very indiscreet to try to establish fees by legislation, for the physician could not undertake to fix by law his fees for practice. There were always men who would work for small fees, but as a rule the companies did not desire such men. The important factor in life insurance for the medical man was that by carrying a policy on his life he was compelled to save money. The speaker believed that the insurance companies would in the next ten years take cognizance of the fact that doctors were not good insurance risks. The mode of life of the physician rendered him an easy mark for various forms of disease, so that it was likely that insurance companies would put doctors in a special category. As to substandard risks, it was true that there were men now going about in perfect health who ten or fifteen years ago were rejected in compliance with the cast iron rules in reference to health, because they had a mitral murmur or a trace of albumin. There were also pulmonary subjects which were rejected. All these cases could be accepted with restrictions.

Dr. WILLIAM HOWARD KING said that he had been dealing with substandard risks for ten or twelve years. Selection began with the agent, who had the applicant make out a trial application which brought out the chief points. When this was received by the medical director, he investigated the doubtful points and, if possible, made the applicant a tentative offer through the agent. If this was satisfactory, the applicant submitted to a medical examination. The examiner was informed in reference to the ques-

tionable points and made special investigation in regard to them. There were various forms of insurance issued to the substandard risks. If the applicant was very little below the standard, the extra hazard might be compensated for by limiting him to an endowment policy or a limited payment, because at the end of the premium paying period the liability of the company ceased. Another method was to advance the age of the insured. For example, the man who was forty might be required to pay the premium of the age of fifty. In investigating the matter of substandard risks it was found, for instance, that those with an intermittent pulse attained to an average survival very much greater than normal. Experience with mitral murmur cases for the past twelve years had been distinctly good. All heart cases were eliminated, if possible.

Dr. T. Hewson Bradford thought there was a wide field for substandard insurance. In his experience a large number of applicants who had been declined because of disability had lived for years in apparent good health. He had recently seen a man of eighty who had been rejected twenty years before because he was under weight and drank a good deal of whiskey. The man informed him that he was still under weight and still drank a good deal of whiskey. If, in a case of mitral murmur, there was good compensation, the speaker saw no reason why an applicant should not be accepted. The rating of the substandards should be done in the actuarial denartment

Mr. FRANK, actuary of the Fidelity Mutual Life Insurance Company, said he thought it well for the insurance officers to hear these discussions, because it informed them as to the point of view of the physi-The only difference that existed seemed to be due to lack of conference and discussion. If there was more discussion between the two parties concerned, there would probably be full agreement. The insurance companies appreciated the value of the medical examiners. The only point of difference seemed to be in reference to the fee. The spirit of this medical society in inviting the insurance representatives to discuss the matter was one of fairness and showed a desire to meet the subject in the proper If this matter could be considered by a joint commission of doctors and insurance officers, the differences could doubtless be adjusted.

Dr. Seltzer said that the importance of substandard risks could be seen when one considered that it was very hard to find a person over forty-five who is flawless. Many of these conditions were transitory and should be dealt with cautiously. It had become a question whether it was really necessary to have a medical examination for policies of \$1,000 or under. The fact that a certain fee was relatively greater in the country than in the city was pointed to as a justification for a sliding scale of fees for the examiner. The average policy in the country was smaller than in the city, ranging from \$1,000 to occasionally \$5,000, while in the city the average policy ranged from \$6,000 upward. Therefore, according to the sliding scale, the city examiner would get more than the country examiner, which was an equitable condition.

Meeting of April 22, 1908.

The President, Dr. ALBERT M. EATON, in the Chair,

A Demonstration of the Method of Taking the Opsonic Index .- Dr. HARRY A. DUNCAN said that the theory of immunity as advocated by Wright put most of the emphasis on the blood serum as the active protective substance of the body, especially that element of the blood which prepared the bacteria so that the leucocytes might ingest and destroy them. To measure the degree of resistance or susceptibility possessed by some patient to any disease caused by germs, all that was necessary was to compare the action of the patient's blood serum upon the bacteria in question with the action of the blood serum of some healthy individual. The influence of the serum upon the germ was noted by observing the number of the germs which the polymorphonuclear leucocytes found suitable for ingestion. To take the opsonic index of a patient, there were needed for the test blood serum from the patient, blood serum from a healthy individual with which to compare it, an emulsion of the bacteria in question, and leucocytes washed free of all adhering serum. The blood sera were secured by centrifuging a few drops of blood which had been collected in a small pipette known as Wright's pipette. The bacterial emulsion was obtained by rubbing up in salt solution a culture of the germ in question grown on an agar slant. The corpuscles were cleaned of all their own serum by washing them repeatedly in salt solution and a five per cent. sodium citrate solution, which prevented clotting, and the centrifuge separated the corpuscles from the washing fluids. Equal quantities of the patient's serum, washed corpuscles, and bacterial emulsion were drawn up into an opsonizing pipette, mixed, and incubated for fifteen minutes at blood heat to give the serum an opportunity to act upon the bacteria and the corpuscles a chance to ingest them. Equal quantities of the healthy serum, washed corpuscles, and bacterial emulsion were treated in the same way in another opsonizing pipette. At the end of the fifteen minutes the contents of these pipettes were expelled on to clean glass slides, smeared, and stained. The number of bacteria ingested by fifty corpuscles acted on by the patient's serum was counted and compared with the number ingested by fifty corpuscles influenced by the healthy serum.

Dr. NATHANIEL BOWDITCH POTTER, of New York, cited some figures illustrating the difficulty in relying upon the opsonic index. In opposition to this, however, he admitted that it had some value. He believed the bacterial inoculations were useful in many instances.

Dr. NATHANIEL GILDERSLEEVE regarded the opsonic index as of very moderate value for diagnostic purposes, but of more value in determining the size of the dose of material to be inoculated and in interspacing the doses.

Dr. G. Morton Illman's experience with taking the opsonic index led him to feel that it was fairly consistent. The greatest success clinically was observed in cases of tuberculosis and in staphylococcic and streptococcic conditions.

The Microscopical Diagnosis of Diseases by Blood Smears.—Dr. L. NAPOLEON BOSTON OUTlined the clinical evidences of unquestionable value obtained by a microscopical study of the blood after it had been smeared upon cover glasses or slides. Given a blood smear, without any further knowledge of the patient from whom it had been obtained, it was possible to make a diagnosis in but a small number of diseases, such as malarial disease, filariasis, chronic plumbism, trypanosomiasis, leuchæmia, chlorotic anæmia, etc. The diseases in which such blood examination might support the further clinical study of the case in question were given as anæmia, with reference to the particular type, pneumonia, sepsis, trichiniasis, infection with intestinal parasites, and all diseases where leucocytosis was present. It was further of service in connection with acute mania, melancholia, poisoning from both mineral and gaseous substances, and conditions resulting from malnutrition, such as syphilis, glandular tuberculosis, etc. A full consideration was given to those diseases where living animal parasites were to be found in the circulating blood, with an outline of the laboratory study.

A Demonstration of the Method of Using the Sphygmograph.—Dr. George W. Norris demonstrated the instrument known as the Jacquet cardiosphygmograph, which was an elaboration of the old clinical sphygmograph, capable of attachment to the wrist in the usual manner. There were, however, in addition to the level which recorded the pulsations of the radial artery, two other levels which could be made to record simultaneously any other two pulsations which it might be desired to take. For example, it was possible to take simultaneous tracings of any two of the following pulsations in addition to that of the radial artery: The jugular pulse, the respiration, the apex beat, a pulsating hydrothorax, an aneurysm, occasionally the right ventricle as well as the left, a pulsating liver, etc. The impulses were transmitted pneumatically from the pulsation to be traced to the recording level. The instrument was also fitted with a time marker which recorded fifths of a second, so that it was possible with the use of calipers to determine the exact duration of any wave. The whole apparatus was small and compact and might readily be carried to the bedside in a small hand bag. This method of studying cardiac disease, it was said, had come prominently forward of late since the great amount of recent physiological and experimental investigation had thrown an entirely new light on many phases of heart disease, especially arrhythmia. By taking a simultaneous tracing of the radial artery, the jugular vein, and the apex beat it was possible to obtain graphic records of the functional performance of each separate chamber of the heart. The cost of the instrument from the manufacturer was \$90 but, thanks to the beneficent high tariff, the American physician had to pay \$130 for it.

Dr. WILLIAM PEPPER pointed out by means of diagrams how the various parts of a tracing taken from the neck could be identified and the causes for the production of these so called A, B, and C waves. Attention was then called as to the way in which, from these various pulsations, information could be obtained of the state of the heart which could be got

in no other way. Chief among the facts so learned might be mentioned the recognition at times of tricuspid lesions, either stenotic or regurgitant, and most important of all, knowledge concerning the contractility and excitability of the heart. Diagrams were exhibited illustrating the different varieties of extra systoles and how they could be classified by studies of the venous pulse into those arising from the ventricle or auricle and those from other points.

Book Aotices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

A Manual of Bacteriology, Clinical and Applied. By R. TANNER HEWLETT, M. D., F. R. C. P., D. P. H. (Lond.), Professor of General Pathology and Bacteriology, King's College, London, etc. Third Edition. London: J. & A. Churchill; 'Philadelphia: P. Blakiston's Son & Co., 1908. Pp. xii-638. (Price, \$4.20.)

This book has many excellent features to commend it, chief among which is the clearness with which all the subjects are discussed and with which the information is arranged. As in most bacteriologies of the present day, a considerable part of the book is devoted to protozoa, and in this part the author gives an excellent account of the various protozoa of medical interest. While it is manifestly impossible in a book of this size to discuss fully any single bacterium, the author has understood how to present the salient points of each organism and their relation to the disease in question. The chapters on the examination of water and the interpretation of the results is especially good, and the same is true of the discussion of disinfection. The book is well printed, and the illustrations are exceptionally fine. The bibliography affords opportunity for further reading to those desiring to do so.

La cura della tisi polmonare mediante il pneumotorace artificiale. Dott. Antonio Pisani. Milan: Società Editrice Libraria, 1908.

In June, 1907, Professor Forlanini announced before the Milan Sanitary Association that he had successfully treated tuberculosis with cavity formation by means of artificial pneumothorax. The treatment consisted in producing and maintaining indefinitely a pneumothorax on the affected side. The opposite lung must, of course, be healthy. The apparatus used consists of a receptacle with nitrogen (the gas injected), a hypodermic needle seven centimetres in length, and a connecting device of rubber, with a double pressure bulb. From 50 to 400 c.c. of gas are injected into the pleura. The gas is filtered through cotton in a glass tube before injection.

In the present pamphlet Dr. Pisani reports ten cases which he has treated with this method. All of these were in the third stage, with pulmonary cavities; six showed pleural adhesions; two, tuberculous laryngitis; and two, tuberculous enteritis. One patient was (clinically) cured; three were greatly improved; and six showed transient improvement. Three patients showed themselves "inclerant to the treatment." The author recommends much larger quantities of nitrogen in this form of

treatment (400 to 500 c.c.), and thinks that better results can be obtained thus than with small and frequent doses. The treatment with artificial pneumothorax, Pisani concludes, is worth trying in the advanced cases of tuberculosis, which have been hitherto abandoned as hopeless. This method, it will be observed, is apparently identical with that proposed several years ago by Dr. John B. Murphy, of Chicago.

Di aleune modificazioni citologiche nel sangue dei frat-turati. Dott. Giuseppe Bernardi. Pisa: F. Mariotti, turati. Dott. 1907. Pp. 105.

The fact that certain changes go on in the blood in cases of fracture has been known for some time, but many points as to the exact characteristics of the leucocytosis of fractures have hitherto remained somewhat obscure. In the present monograph are given the results of researches carried on since 1906 by Bernardi, who examined the blood of animals after producing comminuted fractures (in pigeons, rabbits, and guinea pigs), and also studied the blood of patients with fractures. He found that the leucocytosis accompanying fractures varied according to the age of the animal, the importance of the bone affected, and the severity of the fracture. The leucocytosis reached its maximum in about ten or fifteen days after the accident, and ended with the consolidation of the bony fragments. A few myelocytes are found in all cases of fracture, but their number is not proportionate to the seriousness of the fracture or the age of the patient. A multinuclear leucocytosis is always present, while the lymphocytes are reduced in number. The eosinophiles diminish in number at first, but later increase decidedly, unless complications occur. The scarcity or the disappearance of eosinophiles after the first few days should be regarded as a bad prognostic sign in fractures.

The results obtained by Bernardi are certainly most interesting, and the point just mentioned as to the eosinophilia may, if confirmed by further investigations, come to have an important prognostic bearing in cases of badly healing fractures.

BOOKS, PAMPHLETS, ETC., RECEIVED

A Synopsis of Surgery. By Ernest W. Hey Groves. M. S., M. D., B. Sc. (Lond.), F. R. C. S. (Eng.), Assistant Surgeon to the Bristol General Hospital. New York: William Wood & Co., 1908. Pp. viii-486.

Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commis sioned and other officers of the United States Public Health and Marine Hospital Service for the seven days ending December 9, 1908.

BECK, J. E., Pharmacist. Granted twenty-one days' leave of absence from January 7, 1909.

BILLINGS, W. C., Passed Assistant Surgeon. Bureau orders of November 28, 1908, amended, and directed to report to the Superintendent of the Revenue Cutter Service School of Instruction.

BLUE, RUPERT, Passed Assistant Surgeon. Granted four

BUUE, AUPERT, Fassed Assistant Surgeon. Granted four days' leave of absence from December 9, 1908.

BOWIE, ROBERT I., Sanitary Inspector. Granted six months' leave of absence from February 1, 1909, without pay.

BRANHAM, H. M., Acting Assistant Surgeon. Granted four days' leave of absence from November 10, 1908.

BROWN, F. L., Flarmacist. Granted twenty-five days' leave of absence from Parambers 1009.

Brown, F. L., Flarmacist. Granted twenty-five days' leave of absence from December 7, 1908.

Foster, S. B., Arting Assistant Surgeon. Granted twenty-three days' leave of absence from December 6, 1908.

GAHN, HENRY, Pharmacist. Granted fourteen days' leave of absence from December 14, 1908.

GIRSON, L. P., Arting Assistant Surgeon. Granted five days' leave of absence from December 2, 1908.

days leave of absence from December 2, 1908.

Granted one day's leave of absence, December 3, 1908, under paragraph 191. Service Regulations.

GODMAN, F. S., Pharmacist. Granted fourteen days' leave of absence from December 18, 1908.

HALLETT, E. B., Acting Assistant Surgeon. Granted two days' leave of absence from December 9, 1908.
HURLEY, J. R., Assistant Surgeon. Granted ten days' leave

of absence from December 6, 1908.

KASTLE, JOSEPH H., Chief Division of Chemistry, Hygienic Laboratory. Detailed to represent the Service at the annual meetings of the American Physiological Society and the American Society of Biological Chemists to be held at Baltimore, Md., December 28, 1908, to January

2, 1909.
 Light, S. D. W., Acting Assistant Surgeon. Leave of absence granted November 18, 1908, for twenty-two days from November 17, 1908, amended to read thirty days from November 18, 1908.
 NUTE, A. J., Acting Assistant Surgeon. Granted fourteen days' leave of absence from December 18, 1908.
 Ryder, L. W., Pharmacist. Granted ten days' leave of absence from December 18, 1908.

sence from December 1, 1908.

SWEET, E. A., Passed Assistant Surgeon. Granted one month's leave of absence from November 25, 1908, on account of sickness.

SWEET, E. A., Passed Assistant Surgeon. Relieved from further duty at San Diego, Cal., upon arrival of Surgeon Paul M. Carrington.

TAPPAN, J. W., Acting Assistant Surgeon. Granted ten days' leave of absence en route to station, December 5.

1908. WILSON, J. G., Acting Assistant Surgeon. Granted three days' leave of absence from December 6, 1908, under paragraph 210, Service Regulations.

Board Convened.

Board of medical officers convened to meet at the Marine Hospital in Baltimore, Md., December 7, 1908, for the purpose of conducting a physical examination of a cadet of the U. S. Revenue Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; Passed Assistant Surgeon J. W. Schereschewsky, recorder.

Army Intelligence:

Official list of changes in the stations and duties of offi-cers serving in the Medical Corps of the United States Army for the week ending December 19, 1908;

CRAMPTON, L. W., Colonel, Medical Corps. Relieved from duty in charge of the medical supply depot, St. Louis, Mo., in time to sail March 5, 1909, from San Francisco, Cal., for duty in the Philippines Division.

Greenleaf, H. S., Captain, Medical Corps. Granted leave

of absence for thirty days.

Hoff, J. V. R., Colonel, Medical Corps. Granted leave of absence for two months, with permission to return to the United States via Europe.

Lewis, W. F., Major, Medical Corps. Granted leave of absence for lifteen days.

MAUS, L. M., Colonel, Medical Corps. Relieved from duty as chief surgeon, Department of Luzon, and ordered to report as chief surgeon, Philippines Division; relieved from duty in Philippines Division April 15, 1000, and

ordered to San Francisco, Cal., for orders.

Reed. H. A., Lieutenant, Medical Corps. Ordered to Fort
Bayard, N. M., for treatment at the Army General

Shepherd, J. M., First Lieutenant, Medical Reserve Corps. Died December 11, 1908, at Salt Lake City, Utah, of general peritonitis, complicated with appendicitis.

Torney, G. H., Colonel, Medical Corps. Granted leave of

absence for fifteen days.

Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the week ending December 19, 1908:

ALDERMAN, C. G., Assistant Surgeon. Granted sick leave ALDERMAN, C. G., Assistant Surgeon. Granted sick leave for three months, when discharged from treatment at the naval hospital. Las Animas, Colo.

ALEXANDER, C. E., Pharmacist. Detached from the Relief and ordered home via the Concord and Supply.

BALCH, A. W., Passed Assistant Surgeon. Detached from the naval hospital, Cavite, P. I., and ordered home via the Concord and Supply.

Broom F. H., A. Land Songeon. Detached from the concord and supply.

naval recruiting station, Cleveland, Ohio, and ordered to the Franklin.

Brown, E. W., Assistant Surgeon. Unexpired portion of sick leave revoked; ordered to course of instruction at the Naval Medical School, Washington, D. C.
Butts, H., Assistant Surgeon. Detached from the naval

hospital, Canacao, P. I., and ordered to the naval sta-

tion, Cavite, P. I.

DOWNEY, J. O., Assistant Surgeon. Detached from the Charleston and ordered to duty at the naval hospital, Canacao, P. I.

Higgins, H. E., Assistant Surgeon. Detached from the naval hospital, Canacao, P. I., and ordered to the

Charleston.

LEE, A. E., Assistant Surgeon. Detached from the Concord

and ordered to the Rainbow.

RANDALL, J. A., Passed Assistant Surgeon. Detached from the Rainbow and ordered to duty at the naval hospital, Canacao, P. I.

RUGER—Arbuckle.—In Philadelphia, on Wednesday, De-cember 16th, Dr. Charles Z. W. Ruger and Miss Ella May

Arbuckle.

STONE-PAGE.-In Brookline, Massachusetts, on Monday

STONE—FAGE—In Brooking, Massachusetts, off Monday, December 14th, Dr. William Stephen Stone, of New York, and Miss Catherine Mary Page.

Wertz—Gaines.—In Hagerstown, Maryland, on Thurs day, December 10th, Dr. Irvin M. Wertz and Miss Jane Price Gaines

Died.

Cory.—In New Providence, New Jersey, on Wednesday. December 16th, Dr. Abraham Morrell Cory, aged eightyone years.

DAVIS.-In Pottstown, Pennsylvania, on Friday, Decem-

DAVIS.—In Potstown, reinsylvania, on Prinay, December 11th, Dr. John Davis, aged seventy-six years.

DAVIS.—In Brooklyn, New York, on Monday, December 14th, Dr. Robert Henry Davis, aged eighty-one years.

FIFE.—In San Francisco, California, on Saturday, December 5th, Dr. George Storrs Fife, aged seventy-two

years.

ΗΕΛΟΥ.—In Milford, Connecticut, on Wednesday, December 16th, Dr. E. B. Heady, aged sixty-two years.

ΚΑΦΙΕΝ.—In New York, on Monday, December 14th, Dr.

Marcus A. Kadien, aged forty-nine years.

LE PLONGEON.—In Brooklyn, New York, on Sunday, December 13th, Dr. Augustus Le Plongeon, aged eighty-two

years,
Mackie.—In Milwaukee, Wisconsin, on Wednesday, December 9th, Dr. William Mackie, aged fifty-three years.
Rioux.—In Sherbrooke, Quebec, on Friday, December 18th, Dr. J. F. Rioux.
Roop.—In Harrisburg, Pennsylvania, on Tuesday, De-

Roop.—In Harrisburg, Fennsylvania, on Luesday, De-cember 8th, Dr. J. Warren Roop, aged sixty-five years. Tope.—In Albuquerque, New Mexico, on Friday, Decem-ber 11th, Dr. W. A. Tope, of Downer's Grove, Illinois, aged forty-nine years. Wiscore In Harrisburg, Pennsylvania, on Sunday, De

cember 6th, Dr. Henry Clay Winger.
